**094540 MEASUREMENT OF CHARGE-CARRIER CONCENTRATION IN INDIUM PHOSPHIDE BY MEANS OF AN ELECTROLYTE-SEMICONDUCTOR CONTACT.** An electrolyte-semiconductor contact is used to study the conductivity of epitaxial layers and single crystals of n-type indium phosphide obtained by gas transport. Some of the specimens were alloyed with tin and sulfur. The volt-farad characteristics are used to find the potentials of planar zones, which amount to 0.8-1.3 V for different electrolytes. Values of concentration of charge carriers calculated from measured values of capacitance of the electrolyte-indium-phosphide contact showed good agreement with measurements of the Hall effect on single crystals in the range  $10^{16}$ - $10^{18}$  cm<sup>-3</sup>. The use of measurements of the capacitance of the electrolyte-semiconductor contact with simultaneous etching of a local region made it possible to study the electron distribution in epitaxial layers of indium phosphide. (Author abstract) 12 refs.

**094541 MAGNETOTRANSPORT PROPERTIES AND SUBBAND STRUCTURE OF THE TWO-DIMENSIONAL ELECTRON GAS IN THE INVERSION LAYER OF InSb BICRYSTALS UNDER HYDROSTATIC PRESSURE.** Magnetotransport properties of the n-inversion layer formed at the grain boundary in p-InSb bicrystals are investigated. Hydrostatic pressure up to 10<sup>3</sup> MPa is used to characterize the properties of the two-dimensional electron gas in the inversion layer. At atmospheric pressure in addition to previous results four series of quantum oscillations are revealed, indicating that four electric subbands are occupied. From quantum oscillations of the magnetoresistivity the characteristic parameters of the electric subbands and their pressure dependences are established. A strong decrease of the

carrier concentration in the inversion layer and of the corresponding subband population is observed when pressure is applied. A simple theoretical model is used to calculate the energy diagram of the quantum well and the pressure dependence of the subband parameters. (Edited author abstract) 26 refs.

Herrmann, R. (Humboldt-Universität zu Berlin, Berlin, East Ger); Kraak, W.; Handschack, S.; Schurig, Th.; Kusnick, D.; Schnackenburg, B. *Phys Status Solidi B* v 145 n 1 Jan 1988 p 157-166.

**094542 ON THE DEFORMATION POTENTIALS IN  $\text{CuInSe}_2$  TERNARY SEMICONDUCTORS.** From the analysis of the variation of the energy gap with temperature and pressure in the ternary compound  $\text{CuInSe}_2$ , the valence and conduction band deformation potentials are estimated to be 7.78 and 9.48 eV per unit dilation, respectively. It is found that both the valence and conduction band extrema move to higher energies on compression. It is also suggested that electron-electron scattering combined with polar optical modes has an important influence on the mobility in n-type  $\text{CuInSe}_2$ . (Author abstract) 22 refs.

Rincon, C. (Univ de Los Andes, Merida, Venez.). *J Phys Chem Solids* v 49 n 4 1988 p 391-393.

**094543 INTRINSIC AND DEEP CENTRE CHARGE CARRIERS IN INDIUM ANTIMONIDE.** In the temperature range 150 to 300 K the authors calculate  $n_{IC}$  for an ideal pure  $\text{InSb}$  crystal and also for doped  $\text{InSb:Cr}$  and  $\text{InSb:V}$  samples with deep impurity centres. They analysed the latest available experimental data on  $\text{InSb}$  band parameters and tried to make these data more exact by combining them with intrinsic carrier (IC) data. These results were used for analysis of the temperature dependences  $n(T)$ . The microscopic calculation of the IC concentration is a way to obtain information about deep centres even in cases where the transition to the exhaustion range is not observed. 11 Refs.

**094544 PICOSECOND RAMAN LIGHT-SCATTERING STUDY OF HOT CARRIERS IN  $\text{InP}$ .** We demonstrate a novel method of using picosecond time-resolved Raman scattering to study the kinetics of nonequilibrium carriers in semiconductors. A pump-probe technique employing two separate lasers of different intensities, focal-spot sizes, and pulse durations is used to ensure that a plasma of uniform density is probed. The nonequilibrium-carrier density near the surface of a semi-insulating  $\text{InP}$  sample is estimated by fitting the photoexcited plasmon - longitudinal optical phonon coupled-mode peak in the Raman spectra. The dielectric function used in the calculation includes contributions from intraband transitions of electrons, light holes, and heavy holes as well as from interband transitions of the holes. The temporal evolution of the optically excited carrier population is modelled using a one-dimensional diffusion equation. The ambipolar diffusion constant and the surface-recombination velocity of the nonequilibrium carriers are found to be comparable to estimated values based on extrapolation of equilibrium properties. (Author abstract) 15 refs.

**094546 MONTE CARLO INVESTIGATION OF MINORITY ELECTRON TRANSPORT IN  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$ .** The transport of minority electrons in p-type  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$  has been investigated for doping levels of  $10^{17}$  and  $5 \times 10^{17} \text{ cm}^{-3}$ . It is found that the electrons exhibit smaller velocities at electric fields below 4 kV/cm when the electron-hole interaction is taken into account. The velocities at fields above 4 kV/cm are higher and reach a maximum at 5 kV/cm. The fraction of electrons that transfer to the upper valleys are significantly reduced for electric fields below 6 kV/cm. (Author abstract) 10 refs.

## Chemical Reactions

**094547 LITHIUM INSERTION INTO INDIUM SEQUELENIDE.** The effects of lithium intercalation in  $\text{In}_2\text{Se}_3$  have been studied using different methods. Electrochemical properties of the non-stoichiometric  $\text{Li}_x\text{In}_2\text{Se}_3$  phase are given in the range  $0 \leq x \leq 1$  for either quenched or annealed compounds. Electronic conductivity has been measured during the insertion process in n-butyl lithium and suggests weak charge transfer. The relation between the morphology of samples and insertion mechanism have been discussed. (Author abstract) 25 Refs.

**Chemical Vapor Deposition** See Also SEMICONDUCTING GALLIUM ARSENIDE—Chemical Vapor Deposition.

**094548 REACTOR DESIGN AND OPERATING PROCEDURES FOR  $\text{InP}$  BASED MOCVD.** Important technological difficulties inherent in the MOCVD of  $\text{InP}$  based materials are reviewed together with appropriate solutions. A reactor layout incorporating sophisticated gas switching and pressure control facilities is described, together with options for in situ reagent concentration monitoring. A safe and effective technique for dealing with pyrophoric by-products is discussed. The relative merits of growth at atmospheric pressure and low pressure are considered. Similar performance is noted for the two regimes when preparing low dimensional structures but high background purity has been easier to achieve at low pressure. Persistent photoconductivity has been observed in 'bulk' layers of very high purity  $\text{InP}$  grown at low pressure.  $\text{InP}$  grown at low temperatures exhibits superior morphology when grown with the triethyl rather than trimethyl indium precursor. (Author abstract) 13 refs.

Thrush, E.J. (STC Technology Ltd, Harlow, Engl); Cureton, C.G.; Trigg, J.M.; Stagg, J.P.; Butler, B.R. *Chemtronics* v 2 n 2 Jun 1987 p 62-68.

**094549 MOCVD GROWTH OF  $\text{InP}$  USING RED-PHOSPHORUS AND HYDROGEN PLASMA.**  $\text{InP}$  epitaxial layers have been grown by metalorganic chemical vapor deposition using red-phosphorus and hydrogen plasma alternative to  $\text{PH}_3$  gas cylinder. The carrier concentration was  $3.9 \times 10^{16} \text{ cm}^{-3}$  and the Hall mobility was  $3650 \text{ cm}^2/\text{Vs}$  at 300 K. Quadrupole mass spectrometer showed that the group V sources in this method were  $\text{PH}_3$  and phosphorus vapor. (Author abstract) 9 refs.

**094551 LOW-TEMPERATURE GROWTH OF  $\text{InSb}$  BY VACUUM MOCVD USING  $\text{TEIn}$  AND  $\text{SbH}_3$ .** This report describes the homo-epitaxial growth of  $\text{InSb}$  by the Metal-Organic Chemical Vapor Deposition Method (MOCVD) using triethylindium ( $\text{TEIn}$ ) and stibine ( $\text{SbH}_3$ ) for indium and antimony sources, respectively. Single crystal  $\text{InSb}$  layers were grown at  $400^\circ\text{C}$ . The gas flow rate ratio ( $=\text{SbH}_3/\text{TEIn}$ ) should be more than 8 in order to grow a layer with good morphology. The epitaxial layer was n-type, with a carrier density and mobility of  $1.5 \times 10^{16} \text{ cm}^{-3}$  and  $7.6 \times 10^4 \text{ cm}^2/\text{Vs}$ , respectively, at 77 K. By inserting a buffer layer grown at  $400^\circ\text{C}$ , the single crystal  $\text{InSb}$  layer was grown even at  $300^\circ\text{C}$ . (Author abstract) 5 refs.

**094552 SIMS AND DLTS MEASUREMENTS ON  $\text{Fe}$ -DOPED  $\text{InP}$  EPITAXIAL LAYERS GROWN BY MOCVD.** SIMS and DLTS measurements have been carried out on Fe-doped  $\text{InP}$  epitaxial layers grown by metalorganic chemical vapor deposition (MOCVD). Fe was doped with ferrocene  $\text{Fe}(\text{C}_5\text{H}_5)_2$  and smoothly distributed in the epitaxial layers. The solubility limit of Fe is  $7 \times 10^{16} \text{ cm}^{-3}$  at a growth temperature of  $650^\circ\text{C}$ . A new electrically active defect was observed in  $\text{InP}$  doped with the excess concentration of Fe over the solubility limit. (Author abstract) 10 refs.

Takanohashi, Tsugunori (Fujitsu Lab, Atsugi, Jpn); Nakai, Kenya; Nakajima, Kazuo. *Jpn J Appl Phys Part 2* v 27 n 1 Jan 1988 p 113-115.

**094553 HETEROEPITAXIAL GROWTH OF INDIUM PHOSPHIDE ON SILICON BY MOCVD USING ADDUCT SOURCE.** The heteroepitaxial growth of  $\text{InP}$  on Si by low pressure metalorganic chemical vapor deposition is reported. The trimethylindium-trimethylphosphine adduct was used as the In source in this study. From X-ray and SEM examinations, it can be seen that  $\text{InP}$  epilayers of good crystallinity with mirror-like surfaces can be grown directly on (100) and (111) p-type Si substrates. A carrier concentration profile shows that the carrier distribution in the  $\text{InP}$  epilayer is very uniform. The efficient photoluminescence compared with that of  $\text{InP}$  homoepitaxy shows the good quality of  $\text{InP}/\text{Si}$  epilayers. (Edited author abstract). 8 Refs.

Lee, Ming-Kwie (Nat'l Sun Yat-Sen Univ, Kaohsiung, Taiwan); Tung, Hsin-Hang. *Chung kuo Kung Ch'eng Hsueh K'an* v 11 n 3 May 1988 p 291-294.

**094554 INDIUM TRANSIENTS IN THE GROWTH OF  $\text{InGaAs}$  BY METAL-ORGANIC CHEMICAL VAPOR DEPOSITION.** A study of indium transients in the growth of  $\text{InGaAs-AlGaAs}$  and  $\text{InGaAs-GaAs}$  heterostructures is described for samples grown by atmospheric-pressure metal-organic chemical vapor deposition (MOCVD) using trimethylindium ( $\text{TMin}$ ) and an interrupted growth process. No evidence of large compositional transients and rapid decays in the indium signal are observed in analysis of secondary ion mass spectrometry (SIMS) and sputtered neutral mass spectrometry (SNMS) data taken at the interfaces of both  $\text{InGaAs-GaAs}$  strained-layer superlattice structures and  $\text{InGaAs-AlGaAs}$  laser structures. (Author abstract). 24 Refs.

**094555 EFFICIENCIES OF InAs TRANSPORT AND EPITAXIAL GROWTH BY CHEMICAL VAPOUR DEPOSITION IN THE SYSTEM InAs-AsCl<sub>3</sub>-H<sub>2</sub>.** Efficiencies of InAs transport and epitaxial growth calculated on the basis of thermodynamic considerations and experimentally determined are compared. Parameters optimal with respect to productivity technology for the system InAs-AsCl<sub>3</sub>-H<sub>2</sub> are discussed. From the comparison of calculated and experimental results one can conclude that InAs is transported effectively from the source to the gas phase. This confirms the adequacy of the thermodynamic model to describe the processes taking place at the source zone. The experimental efficiency of InAs epitaxial growth is smaller than that calculated on the basis of the thermodynamic model because of the kinetically controlled growth regime at certain technological conditions. (Edited author abstract). 4 refs.

## Composition Effects

**094557 ELECTRON-MICROSCOPE STUDY OF A NON-STOICHIOMETRIC PHASE IN InSb HEATED IN A VACUUM.** When thin-foil specimens of InSb are heated in the vacuum of an electron microscope, a depletion of Sb takes place because of the preferential evaporation of Sb. This results in the formation of a novel non-stoichiometric (In-rich) solid phase having a cubic structure with a lattice parameter of 5.9 Angstrom, which is about 10% smaller than that of InSb. It has been shown that the twin-orientation relationship exists between the matrix and the non-stoichiometric phase. (Author abstract) 5 refs.

Saka, H. (Nagoya Univ, Nagoya, Jpn); Itoh, K.; Imura, T.; Kamino, T. *Phil Mag Lett* v 56 n 6 Dec 1987 p 225-230.

## Contacts

**094558 INFLUENCE OF INTERFACIAL MORPHOLOGY AND COMPOSITION ON THE BEHAVIOUR OF AuGeNi CONTACTS TO InP.** A correlation between electron microscopy, secondary-ion mass spectroscopy (SIMS) and electrical measurements is reported for AuGeNi alloyed contacts to InP. Changes in the morphology and in the composition of the material at the interface show strong trends as a function of the initial alloy temperature and of subsequent heat treatment to simulate accelerated device operation. Dramatic changes in the electrical properties of the contacts are shown to follow closely and consistently the changes in morphology. The principal factor controlling the stability of the contact appears to be the thickness and integrity of a new AuGeP phase at the interface. Growth of large particles of Au<sub>2</sub>P<sub>3</sub> occurs at high alloy temperatures or after prolonged heat treatment and is strongly associated with contact degradation. There was no evidence for preferential Ge diffusion. Various models for current transport across the metal-semiconductor interface are discussed as well as the implications for the control of contact resistance. (Author abstract) 30 refs.

**094559 EFFECT OF THE SURFACE COMPOSITION OF INDIUM PHOSPHIDE ON THE BARRIER HEIGHT AT A P-InP-Ag CONTACT.** Metal-semiconductor contacts are now widely used in various semiconductor devices. This explains the interest in studying the barrier formation mechanism in such contacts and the influence of various factors on the height of this barrier. Such investigations are generally carried out on semiconductors whose surface is cleaned by chemical etching and is coated by a thin oxide layer or on the surface of semiconductors obtained by cleaving in an ultrahigh vacuum. This paper presents the results of an investigation of the p-InP-Ag contact, fabricated on the surface of epitaxial InP layers after they have been cleaned by heating in an ultrahigh vacuum. The effect of surface impurities on the height of the potential barrier at the contact is investigated. 6 refs.

## Corrosion

**094560 FORMATION AND CORROSION PROCESSES OF COLLOIDAL In<sub>2</sub>Se<sub>3</sub>.** Colloids of an In<sub>2</sub>Se<sub>3</sub> layered-type semiconductor were prepared in aqueous medium in the presence of sodium metaphosphate. Formation of the crystalline colloids was followed spectrophotometrically. The reactions of OH CO<sub>2</sub><sup>-</sup>, and (CH<sub>3</sub>)<sub>2</sub>COH radicals with In<sub>2</sub>Se<sub>3</sub> particles were investigated by pulse radiolysis. Both oxidation and reduction of the colloids led to bleaching of semiconductor absorption. The bleaching was much more pronounced in anodic (oxidative) than in cathodic (reductive) corrosion processes. Decomposition by both processes resulted in disappearance of the 'structured' absorption of small particles. Bleaching was also observed upon laser flash photolysis of semiconductor colloids in the absence of scavengers. (Author abstract) 26 refs.

## Defects See Also CRYSTALS—Dislocations.

**094562 DEFECT STRUCTURES IN InP CRYSTALS BY LASER SCANNING TOMOGRAPHY.** Laser-beam scanning tomography (infrared light scattering tomography) images are taken from various InP crystals. They all display a distribution of bright points which are shown to be statistically arranged along the crystallographic axes <100> and <110>. These microdefects are likely distributed along dislocations in such a way that small volumes or 'cells' (typically 200-500 μm wide) are kept free from defects. It is shown that the density varies with the doping of the material; lower densities were observed in Fe-doped InP crystals. (Edited author abstract) 10 refs.

Fillard, J.P. (Univ de Sciences et Techniques du Languedoc,

Montpellier, Fr); Gall, P.; Baroudi, A.; George, A.; Bonnafé, J. *Jpn J Appl Phys Part 2* v 26 n 8 Aug 1987 p 1255-1257.

**094563 STUDY OF STATIC ATOMIC DISPLACEMENTS BY CHANNELLED-ELECTRON-BEAM-INDUCED X-RAY EMISSION: APPLICATION TO In<sub>0.53</sub>Ga<sub>0.47</sub>As ALLOYS.** A novel method for detecting and measuring the static atomic displacements from the perfect crystal sites existing in some alloys is investigated. The method uses the influence of the channeling of an electron beam on the ratio of the numbers of characteristic X-rays emitted by two atoms which are displaced differently with respect to the average lattice planes. Calculations taking into account the delocalization of the ionizing events and the atoms' thermal vibrations show that displacements smaller than 0.01 nm should be detectable. This is confirmed by an experimental STEM study of thin In<sub>0.53</sub>Ga<sub>0.47</sub>As epitaxial layers, where the arsenic atoms are shown to be displaced from the perfect crystal sites more than are the indium and gallium atoms. (Author abstract) 30 refs.

**094564 OBSERVATION OF CELLULAR STRUCTURES OF DEFECTS IN SEMI-INSULATING InP-Fe.** GaAs semi-insulating materials reveal an organization of defects which appears in (001) wafers as a pattern of cells. This typical arrangement is displayed in surface etch images as well as X-ray topographies, infrared transmission and so on. It is shown that a similar organization also exists in InP wafers: its visualization is not easy because of a weak contrast in the image: their observation requires a strong contrast enhancement by numerical processing. The structure could be related to entangled dislocations along shear stress planes resulting from the post growth cooling process. They are observed as very bright points in laser scanning tomography. These cellular patterns are not as dependent on the origin of the crystal and the typical average dimensions are in the range of 200-300 μm (similar to GaAs) which means that they fit within the dimensions of most optoelectronic integrated circuits. The macrospecific arrangement of cells does not display the tetragonal symmetry often observed on GaAs materials. (Edited author abstract) 18 refs.

**094565 ON THE POSSIBILITY OF FORMATION OF ASSOCIATED IMPURITY CENTERS IN SEMI-INSULATING INDIUM PHOSPHIDE DOPED BY OXYGEN.** The purpose of the note is the investigation of the photoelectrical properties of indium phosphide doped by iron and oxygen simultaneously. The impurities were introduced into the melt as Fe or Fe+In<sub>2</sub>O<sub>3</sub>. The amount of iron was kept constant (0.08 wt. percent) whereas the In<sub>2</sub>O<sub>3</sub> content was changed (0.04 to 0.40 wt. percent). Investigations of the photoconductivity (PC) were carried out using standard synchronous detection techniques in the temperature range 80 to 300K. Double doping by iron and oxygen leads to a noticeable change in the photoelectric properties of the material. x Refs.

## Deformation

**094567 DYNAMICAL RECOVERY AND SELF-DIFFUSION IN InP.** Single crystals of InP with <123> orientation have been deformed at constant strain rates at temperatures between 540 and 780°C. The resulting stress-strain curves are rather similar to those obtained for other semiconductors such as Ge, Si and InSb, and two stages of dynamical recovery can be clearly identified. From the strain-rate and temperature dependencies of the stress at the beginning of the first recovery stage, an activation energy of 2.3 eV is deduced. This may be regarded as a lower bound for the activation energy of self-diffusion of the slowest-moving species; for the pre-exponential factor  $D_0$  of the diffusion coefficient a value between  $10^{-3}$  and  $10^{-2}$  cm<sup>2</sup> s<sup>-1</sup> is estimated. (Author abstract) 37 refs.

## Diffusion

**094568 SULPHUR DIFFUSION INTO InP BY AN OPEN TUBE PROCESS.** A technique is described for the diffusion of sulphur into InP by an open tube process, which gives highly reproducible results from run to run, as required for device applications. A vacuum-deposited layer of gallium sulphide (Ga<sub>2</sub>S<sub>3</sub>) was used as the source for sulphur diffusion, with a chemically vapor deposited SiO<sub>2</sub> cap layer of preventing decomposition of the InP surface during heat treatment. Diffusions were carried out at temperatures ranging from 585°C to 708°C. Diffused layers were characterized by the surface carrier concentration and diffusion constant. From these measurements the diffusion profile for sulphur in InP is estimated to be of the complementary error function type. The activation energy of the diffusion was estimated to be 1.94 eV. The technique is ideally suited for the fabrication of shallow n+p junctions in InP, and has been used successfully for space-borne solar cells. (Edited author abstract) 12 refs.

**094571 STUDY OF RESIDUAL BACKGROUND DOPING IN HIGH PURITY INDIUM PHOSPHIDE GROWN BY ATMOSPHERIC PRESSURE OMVPE.** High purity InP epilayers have been grown by OMVPE with 77 K mobilities as high as  $119000$  cm<sup>2</sup> V<sup>-1</sup> s<sup>-1</sup> using TMI<sub>n</sub> specially purified via the diphos route. The effect of growth rate, growth temperature and V/III ratio on background doping and mobility is reported. Silicon is identified as the residual impurity in the epilayers. (Author abstract) 17 refs.

**094572 PROPERTIES OF InP DOPED WITH 4d IONS.** We have grown InP crystals doped with elements from the second long period (Nb, Mo, Ru, Rh and Pd) by the high-pressure gradient freeze method or by the liquid encapsulated Czochralski technique. Samples have been characterized electrically by Hall effect measurements and chemically analyzed by spark source mass spectroscopy and secondary-ion mass spectrometry. We found the 4d impurities are introduced with a concentration of many  $10^{15}$  cm<sup>-3</sup>. Nevertheless by spectroscopic measurements (electron paramagnetic resonance, photoluminescence and optical absorption) we have detected no lines which could be related to a ground or an excited state of the 4d impurity in isolated form. By deep-level spectroscopy, we detect only one hole trap in the concentration range of a few  $10^{15}$  cm<sup>-3</sup> which can be related to the 4d doping. The energy position of this trap is independent of the impurity and is found at 0.15-0.2 eV from the valence band. (Edited author abstract) 28 refs.

**094573 FLUORESCENCE EXAFS STUDY OF Zn-DOPED LEC InP CRYSTAL.** Interatomic distance between Zn impurity atom and P host atom in LEC InP:Zn was determined by extended X-ray absorption fine structure by monitoring the Zn K<sub>α</sub> fluorescence yield. The measured Zn-P interatomic distance remained the value of 2.42 Å, which was in excellent agreement with the distance 2.41 Å calculated from Pauling's tetrahedral radii for zincblende structure. From XANES spectra, strong lattice distortion was observed around the Zn atom. (Author abstract) 19 refs.

**094574 ELECTROCHEMICAL AND STRUCTURAL ASPECTS OF LITHIUM INSERTION INTO THE NEW LAYERED COMPOUND CdIn<sub>2</sub>S<sub>2</sub>Se<sub>2</sub>.** Electrochemical lithium insertion in pure and (PTFE-and/or C-) mixed CdIn<sub>2</sub>S<sub>2</sub>Se<sub>2</sub> has been investigated by galvanostatic discharge experiments. Structural changes induced by lithium insertion have been observed by powder X-ray diffraction measurements. The reversibility of the process is poor in the whole range explored, but differences in behaviour are noticed. Analyses of the results evidence that CdIn<sub>2</sub>S<sub>2</sub>Se<sub>2</sub> is a very interesting new compound, more significant for its fundamental properties than in view of its application as cathode material in aprotic solvent lithium cells. (Edited author abstract) 23 refs.

**094575 EFFECT OF THE InP DOPING DENSITY ON THE ELECTRICAL PROPERTIES OF THE TWO-DIMENSIONAL ELECTRON GAS IN LPE-GROWN MODULATION-DOPED HETEROSTRUCTURES.** In<sub>0.53</sub>Ga<sub>0.47</sub>As/n-InP modulation-doped heterostructures have been grown by liquid phase epitaxy. Shubnikov-de Haas and quantum Hall effect measurements were taken for the confirmation of the existence of the two-dimensional electron gas (2DEG). Mobility enhancements were observed at low temperatures from the variable-temperature Hall measurements. When the doping density of InP layer was varied from  $2.1 \times 10^{17}$  to the  $5.2 \times 10^{18}$  cm<sup>-3</sup>, the sheet electron density and mobility of 2DEG at 10 K were changed from  $6.52 \times 10^{11}$  to  $1.01 \times 10^{12}$  cm<sup>-2</sup> and 49,500-43,600 cm<sup>2</sup>/v-s, respectively. From the recordings of high-field Hall plateaus, the channel densities were  $4.03 \times 10^{11}$  and  $6.03 \times 10^{11}$  cm<sup>-3</sup>, respectively. The corresponding Fermi energies were 20.1 and 29.9 meV measured from the lowest energy level in the potential well. (Author abstract) 29 refs.

**094576 DOPING INHOMOGENEITIES AND COMPENSATION IN n-TYPE LEC InP WAFERS.** Lateral scans of free carrier infrared absorption with lateral resolution of 100 μm and Hall effect measurements were performed across (001) wafers cut from Sn- and S-doped 111 direction crystals. Considerable microinhomogeneities as well as macroinhomogeneities are detected in the distributions of the concentrations of free carriers, donors, and compensating acceptors. The macroinhomogeneities are due to growth facets representing regions of increased carrier concentration, while the microinhomogeneities are growth striations appearing both in and outside of facets. This behaviour may be understood by considering the growth direction of the crystals. Reasons for differences between the optical and electrical values of the compensation ratio as well as possible origins of the compensating acceptors are discussed. (Edited author abstract) 16 Refs.

**094577 EFFECT OF COOLING AMBIENT ON ELECTRICAL ACTIVATION OF DOPANTS IN MOVPE OF InP.** The electrical doping level of p-InP (Zn or Cd) cooled from typical MOVPE growth temperatures is strongly dependent on the gaseous cooling ambient. This is the result of electrical deactivation rather than loss of the dopant. Atomic H is found in samples cooled in AsH<sub>3</sub> or PH<sub>3</sub> and the possibility of an H passivation mechanism is discussed. (Author abstract) 6 Refs.

## Electric Conductivity

**094578 ELECTRICAL TRANSPORT PROPERTIES OF INDIUM SELENIDE SINGLE CRYSTALS.** Electrical conductivity and Hall effect measurements were performed on InSe single crystals grown by the Bridgman Stockbarger method. The measurements were carried out both along the c-axis and perpendicular to it. The samples were of n-type nature in the whole temperature range from liquid nitrogen temperature up to 500 K. The anisotropy properties of n-type InSe crystals at temperatures 77-500 K were investigated. The electrical conductivity measured when the current was oriented at right angles to the c-axis ( $\sigma_{\perp}$ ) was found to be higher than the conductivity measured parallel to the c-axis ( $\sigma_{\parallel}$ ). The anisotropy in the electron mobility was also observed. It is seen that at room temperature the concentration of free carriers lies between  $10^{13}$  and  $10^{14}$  cm<sup>-3</sup>. (Edited author abstract) 12 refs.

Hussein, S.A. (Assiut Univ, Qena, Egypt); Nagat, A.T.; Hafez, A.M.; Gameel, Y.H.; Belal, A.A. *Indian J Pure Appl Phys* v 25 n 7-8 Jul-Aug 1987 p 278-281.

**094579 ELECTRICAL CONDUCTIVITY ANISOTROPY IN TIN-DOPED n-TYPE INDIUM SELENIDE.** Electrical conductivity anisotropy of n-type indium selenide samples doped with different concentrations of tin is studied between 30 and 300 K. The anisotropy ratio is found to depend exponentially on the inverse temperature, the activation energy  $E$ , and the pre-exponential factor varying with free carrier concentration. This behavior is explained by the existence of potential wells created by planar aggregates of ionized donor impurities screened by free electrons. A simple model in which the depth of these potential wells is calculated as a function of temperature, charge density in the planar defects, and electron concentration, gives account of the measured activation energies, but does not explain the high value of the anisotropy ratio. The existence of strictly two-dimensional electrons bound to planar defects not contributing to the electrical conduction across the layers is proposed to explain this result. (Author abstract) 17 refs.

**094580 FINITE FREQUENCY SCALING OF HOPPING CONDUCTIVITY IN n-IN5Sb.** Conductivity measurements on three disc-shaped n-In5Sb samples were carried out in magnetic fields up to 70 kG at temperatures down to 40 mK and over a frequency range of 0-10<sup>5</sup> Hz. A scaling formula was found for AC and DC conductivity in the hopping conduction region. The value of a parameter in the equation is found to agree with the value predicted by theory for some semiconductor materials with a constant density of states at the Fermi level. (Edited author abstract) 18 refs.

Abboudy, S. (Univ of London, Egham, Engl); Fozzoni, P.; Mansfield, R.; Lea, M.J. *Phil Mag Lett* v 57 n 5 May 1988 p 277-282.

**094581 HOPPING CONDUCTION IN n-TYPE INDIUM PHOSPHIDE.** Measurements of the resistivity of three samples of n-InP with  $N_D - N_A = 4.8, 5.9$  and  $7.8 \times 10^{15} \text{ cm}^{-3}$  in magnetic fields up to 70 kG and for temperatures down to 60 mK are described. The theoretical resistivity in zero magnetic field is in good agreement with experiment for both nearest-neighbor and variable-range hopping, provided that an enhanced dielectric constant is used, which is required to reduce the theoretical hopping activation energy to the measured  $\epsilon_3$ . It is found that the temperature dependence of the pre-exponential factor is significant and that  $\epsilon_3$  should be determined from  $\ln(\rho/T)$  against  $T^{-1}$  plots. This also applies to the determination of  $T_0$  in the variable-range hopping region. The magnetoresistance in the weak-field limit for the nearest-neighbor-hopping region confirms previously reported measurements, and the anisotropy of the magnetoresistance agrees closely with the expected  $(H/4H_c)^2$  dependence. (Edited author abstract) 16 refs.

## Electric Field Effects

**094582 ELECTRON GAS HEATING AND COOLING EFFECTS BY MICROWAVE ELECTRIC FIELDS IN COMPENSATED InSb.** Data of an experimental investigation of the electron gas cooling in compensated indium antimonide in a warming electric field are presented. The electron average energy was determined from the hot electron thermoelectromotive force arising on opposite ends of the graded n-n<sup>+</sup> junction placed in a microwave electric field. It is found that at liquid nitrogen temperature, in the samples with electron density  $n < 2 \cdot 10^{12} \text{ cm}^{-3}$ , the average energy of an electron decreases in comparison with the equilibrium value in a certain range of electric fields. The dependences of the longitudinal and transverse diffusion coefficients on the amplitude

of microwave electric field were deduced from the hot electron thermoelectromotive force. (Edited author abstract) 9 refs.

**Electric Properties** See Also SEMICONDUCTOR DIODES—Tunneling.

**094583 ELECTRICAL PROPERTIES OF Fe-DOPED SEMI-INSULATING InP AFTER PROTON BOMBARDMENT AND ANNEALING.** The effects of proton bombardment and subsequent 30-min annealing on the electrical properties of semi-insulating InP doped with Fe at concentrations from  $9 \times 10^{15}$  to  $2 \times 10^{17} \text{ cm}^{-3}$  have been measured for proton doses from  $1.0 \times 10^{12}$  to  $4.4 \times 10^{15} \text{ cm}^{-2}$  and for annealing temperatures from 80 to 750°C. Proton bombardment decreases the sheet resistivity to as low as  $3 \times 10^4 \Omega/\square$ . The sheet resistivity is further decreased by annealing at temperatures up to 200-250°C but is increased by annealing at higher temperatures. Semi-insulating behavior is restored by annealing at 450°C or above. These changes can be explained by the formation of donor and acceptor defects at relative rates that vary with proton dose and by the removal of these defects at relative rates that vary with annealing temperature, although a variation in the effectiveness of the Fe acceptors or a hopping contribution to the conductivity may also play a role. (Author abstract) 8 refs.

**094584 SCATTERING MECHANISMS OF THE HALL EFFECT AND TRANSVERSE MAGNETORESISTANCE IN NON-DEGENERATE PIEZO-ELECTRIC SEMICONDUCTORS.** The Hall effect and transverse magnetoresistance in the intrinsic non-degenerate semiconductors InSb and GaAs have been investigated according to the scattering processes of carriers in solids. These scattering processes include the acoustic phonon scattering, piezo-electric scattering and ionized-impurity scattering. The energy band structure of carriers is assumed to be non-parabolic. Results show that the Hall angle, the Hall coefficient, and the transverse magnetoresistance depend strongly on the dc magnetic field due to the energy-dependent relaxation time. A comparison between experimental work and theory for the Hall effect and transverse magnetoresistance in InSb has been made. The effect of non-parabolicity in InSb has also been discussed in comparison with the numerical results for the parabolic band structure. (Edited author abstract) 37 refs.

**094585 ELECTRICAL CONTACTS TO SEMICONDUCTING INDIUM TELLURIDE FILMS.** Thin films of indium telluride were prepared by thermal evaporation of the bulk compound in vacuum. When a stoichiometric bulk is evaporated in vacuum, the resulting film is often non-stoichiometric. Hence, a detailed analysis of the dependence of film composition on the composition of the bulk was carried out. The effect of temperature on the nature of the contacts was studied on an In-InTe-In structure. In order to study the mechanism of conduction, Al-InTe-In sandwich structures were prepared with aluminum and indium as the lower and upper contacts, respectively. The linear dependence of  $\log I$  on  $V^{1/2}$  indicates Schottky emission to be the dominant electron transfer mechanism. 10 refs.

Rousina, Roughieh (Sardar Patel Univ, Gujarat, India); Shivakumar, G.K. *J Mater Sci Lett* v 7 n 5 May 1988 p 463-465.

**094586 ELECTRICAL PROPERTIES OF Cd-DOPED p-InSe.** Results are presented on the temperature dependences of the hole concentration and the Hall mobility in Cd-doped p-InSe, and the acceptor level

related to Cd atoms is characterized. Furthermore, the relationship between the mobility and the impurity concentration is discussed. Single crystals of p-type InSe were grown by a conventional Bridgman technique. Cd of 99.99 percent purity was doped from 0.1 to 1 at percent to the stoichiometric melt of InSe. The results of x-ray measurements showed that these p-type InSe belong to the  $\gamma$ -polytype as in the case for not purposely doped n-type InSe. In conclusion, the carrier transport of Cd-doped p-InSe is dominated by the acceptor level at 0.45 eV above the valence band. The temperature dependence of the hole mobility can be well fitted by the combined mobility of the optical phonon and the ionized impurity scatterings. 13 Refs.

**094587 ELECTRICAL CHARACTERIZATION OF n-INP GROWN BY METAL-ORGANIC VAPOUR-PHASE EPITAXY.** At room-temperature, the Hall mobility observed in epitaxial n-InP samples grown by metal-organic vapour-phase epitaxy is often lower than predicted, with a corresponding rise in the electronic concentration. These effects are attributed to the presence of a residual deep donor center that both acts as a strong scatterer and provides the additional electronic excitation observed at high temperature as it ionizes. A binding energy of 215 meV is consistent with both electrical-transport measurements and the observed photoluminescence. (Author abstract) 21 refs.

## Electronic Properties

**094588 LOCALISATION EFFECTS CAUSED BY THE REMOTE DONORS IN MODULATION-DOPED QUANTUM WELLS.** We have developed a theoretical model to determine the size and scale of potential fluctuations  $2\eta$  created in the 2D electron gas in the QW by the random distribution of ionized donors modeled as a 2D sheet. We show that for  $E_{FE} > \eta$  all electrons are localized at low temperature, while for  $E_{FE} < \eta$  there are both localized and free electrons. This behavior manifests itself in experimental results of mobility measurements using persistent photoconductivity which exhibit a mobility edge. Photoluminescence results where the oscillator strength for the localized electrons is suppressed compared with free electrons recombining with the few photo-excited localized holes also support this theory since the fluctuations separate the localized electrons and holes in real space. (Edited author abstract) 22 refs.

**094589 CYCLOTRON RESONANCE IN THE n-INVERSION LAYER OF InSb GRAIN BOUNDARIES.** We report the observation of the cyclotron resonance of electrons in a grain boundary inversion layer. We provide transmission measurements on a p-type InSb bicrystal at discrete wavelengths between  $\lambda = 70.6 \mu\text{m}$  and  $251 \mu\text{m}$  using an optically pumped molecular gas laser. The observed cyclotron resonance spectra consisting of the cyclotron resonance lines of at least three electric subbands do not allow a direct determination of the cyclotron masses of the different electric subbands because of the large linewidth of several lines. (Edited author abstract) 11 refs.

Mueller, H.-U. (Univ zu Berlin, Berlin, East Ger); Ludwig, F.; Herrmann, R. *Solid State Commun* v 65 n 7 Feb 1988 p 761-763.

**094590 CHARACTERISTICS OF DISORDER IN DEFECTIVE LAYERED SEMICONDUCTOR  $\alpha$ - $\text{In}_2\text{Se}_3$ .**  $\text{In}_2\text{Se}_3$  which crystallizes in layer structure has been studied at different post preparation temperatures. The presence of a large number of intrinsic defects affects strongly its electrical and optical properties. Our experiments aimed at measuring the influence of the post-preparation annealing on conductivity and anisotropy. From FIR spectroscopy the reflectivity spectrum is found to be included by crystal disorder. Photoluminescence measurements are also included and provide valuable information concerning the crystal degree of ordering. (Author abstract) 10 refs.

Kambas, K. (Aristotle Univ of Thessaloniki, Thessaloniki, Greece); Fotis, J.; Hatzikrantonis, E.; Julien, C. *Phys Scr* v 37 n 3 Mar 1988 p 397-400.

**094591 HIGH MOBILITY TWO-DIMENSIONAL ELECTRON GAS IN  $\text{InP}/\text{Ga}_{0.47}\text{In}_{0.53}\text{As}$  HETEROJUNCTIONS GROWN BY LOW-PRESSURE ORGANOMETALLIC VAPOUR PHASE EPITAXY.** The two-dimensional electron gas in  $\text{InP}/\text{GaInAs}$  heterojunctions, grown by LP-OMVPE, showed Hall mobilities as high as 164 000 and 103 000  $\text{cm}^2/\text{Vs}$  at 4 K and 80 K, respectively. A maximum Hall mobility of 172 000  $\text{cm}^2/\text{Vs}$  was measured at 20 K. Shubnikov-de Haas oscillations measured at 200 mK in magnetic fields up to 20 T indicated the total absence of parallel conduction. By illuminating the sample it was possible to populate the second electrical sub-band at a total carrier density  $n_s = 4.4 \times 10^{11} \text{ cm}^{-2}$ . (Author abstract) 7 refs.

**094594 COMPARISON OF THE ELECTRONIC PROPERTIES OF THIN-PERIOD (INAS)(GAAS) AND (INAS)(ALAS) SUPERLATTICES WITH COMPOSITIONALLY SIMILAR RANDOM ALLOYS.** A comparison is made between the electronic properties of the (InAs)(GaAs) and (InAs)(AlAs) superlattices with their compositionally similar random alloys. While the long-range order in the superlattice can dramatically reduce the effect of alloy scattering on both transport and excitonic linewidth, the electronic properties of the thin-period superlattice are similar to the alloy with major differences occurring only in the hole states. Since the band-edge lineup at strained heterointerfaces is largely unknown, the authors present the dependence of the bandgap, the electron and hole effective masses and the separation between the heavy and light hole bands at the center of the Brillouin zone with respect to the band-edge lineup. Calculations show that thin-period strained super-

lattices using these systems could have excellent potential for high-speed devices. 19 refs.

Jaffe, Mark (Univ of Michigan, Ann Arbor, MI, USA); Singh, Jasprit. *IEEE Trans Electron Devices* v ED-34 n 12 Dec 1987, 1987 IEEE Microwave and Millimeter-Wave Monolithic Circuits Symp, Jun 8-9 1987 p 2540-2545.

**094595 DEEP LEVELS IN n- $\text{InP}$ .** Seven electron traps and two hole traps have been detected on various n- $\text{InP}$  samples of high-quality Au/ $\text{InP}$  Schottky barrier and p+n junction structures by using DLTS technique. We propose that electron trap  $\text{ME}_1$  ( $E_C$ -0.69eV) observed for the first time is related to impurity iron, and the commonly detectable electron trap  $\text{ME}_2$  ( $E_C$ -0.62eV) is probably caused by native defect or residual impurity other than iron. (Author abstract) 2 refs.

Hu, B.H. (Acad Sinica, Shanghai, China); Zhou, B.L.; Chen, Z.X. *J Lumin* v 40-41 Feb 1988, Excited State Processes in Condensed Matter, Proc of the Int Conf on Lumin, Beijing, China, Aug 17-21 1987 p 371-372.

**094596 ELECTRON TUNNELLING INTO INTERFACIAL LANDAU STATES IN SINGLE BARRIER n-TYPE  $(\text{InGa})\text{As}/\text{InP}/(\text{InGa})\text{As}$  HETEROSTRUCTURES.** A new type of tunnelling phenomenon in forward-biased single-barrier  $n^+(\text{InGa})\text{As}/n^-(\text{InGa})\text{As}/\text{InP}/n^+(\text{InGa})\text{As}/n^+(\text{InGa})\text{As}$  heterostructures has been observed when a quantizing magnetic field is applied in the plane of the  $\text{InP}$  barrier. The occurrence of two distinct series of resonances in the voltage- or field-dependence of the current is interpreted in terms of electron tunnelling from a 2DEG in the  $n^-$  layer into interfacial Landau states in the  $n^+(\text{InGa})\text{As}$ . These states correspond to classical skipping orbits of an electron along the tunnel barrier interface. For devices in which the  $n^+(\text{InGa})\text{As}/n^+\text{InP}$  interface at the back end of the gate is within approximately 0.3  $\mu\text{m}$  of the barrier, the interfacial Landau states are observed to evolve into box-quantized states as the magnetic field is reduced to zero. (Author abstract) 9 refs.

**094599 PREFERENTIAL PHOTOELECTROCHEMICAL ETCHING IN n- $\text{InP}$ .** A V-shaped groove was obtained on n- $\text{InP}$  with a maskless photoelectrochemical method by scanning a laser spot. The groove

profile changes with the number of scans, beginning with a flat bottom and ending with a V profile. All these etched shapes depend on the reactivity of the various crystallographic planes and on exposure time. (Author abstract) 7 refs.

Moutonnet, D. (CNET, Lannion, Fr). *Mater Lett* v 6 n 5-6 Mar 1988 p 183-185.

**094600 SURFACE ORIENTATION EFFECT ON PHOTOELECTROCHEMICAL ETCHING IN n-TYPE  $\text{InP}$ .** The effect of surface orientation on photoelectrochemical etching in n-type  $\text{InP}$  is studied. The (111) planes are of special interest because of their surface composition, only consisting of group III atoms (111) or of group V atoms ( $1\bar{1}\bar{1}$ ). A comparison with etching of the (100) face with acidic solution has shown the great dependence of etching morphology with P or In atom quantities. Following the different reactivities of group III and group V atoms, the etching seems to be always initiated by oxidizing of P atoms. These are directly apparent on the (100) and (111) faces and become apparent in surface defects on the (111) face. (Author abstract) 7 Refs.

## Fracture

**094601 INDENTATION FRACTURE IN THE  $\text{In}_{1-x}\text{Ga}_x\text{As}_y\text{P}_{1-y}/\text{InP}$  SYSTEM AND ITS EFFECT ON MICROHARDNESS ANISOTROPY CHARACTERISTICS.** Knoop microhardness anisotropy measurements on the  $\text{In}_{1-x}\text{Ga}_x\text{As}_y\text{P}_{1-y}/\text{InP}$  system have disclosed an appreciable variation in hardness behaviour across the composition range of the alloy. This paper relates these variations to changes in the directional fracture characteristics of the system. The qualitative investigation of both Vickers and Knoop indentation fracture has established the emergence of a secondary  $<100>$  cleavage direction at high values of the composition parameter. The marked change in Knoop microhardness anisotropy characteristics with increasing y in the  $\text{In}_{1-x}\text{Ga}_x\text{As}_y\text{P}_{1-y}/\text{InP}$  system has been partially correlated to the emergence of  $<100>$  cleavage and the general increase in indentation fracture, highlighted by the quantitative fracture measurements. Thus, it is concluded that even at very low indentation loads, the effect of fracture on the measured hardness of crystalline materials cannot be ignored. (Edited author abstract) 32 refs.

**094602 LIQUID PHASE EPITAXY AND CHARACTERIZATION OF RARE-EARTH-ION (Yb, Er) DOPED  $\text{InP}$ .** Yb-doped  $\text{InP}$  was grown by liquid phase epitaxy (LPE). Results of photoluminescence (PL) and secondary ion mass spectroscopy (SIMS) measurements revealed that Yb ions are not uniformly dispersed in the crystals but rather incorporated in the crystals as micro particles of Yb-rich compounds. It results in low reproducibility of the epitaxially grown crystals, and relatively weak Yb-related luminescence in spite of the high average Yb concentration in the crystals. Preliminary experimental results on Er-doped  $\text{InP}$  and  $\text{InGaAsP}$  also revealed formation of Er-rich micro particles within the epitaxial crystals. This seems to be the reasons for reported difficulties in fabricating high quality, reproducible, Er-doped  $\text{InP}/\text{InGaAsP}$  double heterostructure lasers by LPE. (Author abstract) 8 refs.

**094603 COMPOSITIONAL HOMOGENEITY OF MOVPE-GROWN  $\text{In}_x\text{Ga}_{1-x}\text{As}$ : DEPENDENCE ON REACTOR WALL TEMPERATURE AND WORKING PRESSURE.** The compositional homogeneity of MOVPE-grown in  $\text{In}_x\text{Ga}_{1-x}\text{As}$  layers over an area of  $5.5 \times 10 \text{ cm}^2$  is investigated. The various conditions under which these layers were grown are atmospheric pressure and low pressure as well as cold and hot reactor walls. At atmospheric pressure a cold reactor wall initiates a convective vortex, a hot reactor wall yields parasitic depositions on the reactor wall. At low pressure the layer composition is found to be nearly independent of the wall temperature. Layers with a high compositional homogeneity of about 1% over an area of two 2 inch wafers can be grown at a total pressure of 100 mbar. (Author abstract) 6 refs.

**094604 ELECTROABSORPTIVE  $\text{In}_{1-x}\text{Ga}_x\text{As}_y\text{P}_{1-y}$  SUPERLATTICES GROWN BY LIQUID PHASE EPITAXY.** An automatically controlled liquid phase epitaxy process has been developed for the growth of superlattice structures with layers in the thickness range 50-300 nm. Homojunction structures in  $\text{InP}$  or  $\text{In}_{1-x}\text{Ga}_x\text{As}_y\text{P}_{1-y}$  have been grown with from 18 to 102 alternating p and n layers. Heterostructures with undoped layers of smaller band-gap separating the p and n layers have also been produced. A sideways offset of the position of the solutions allowed all p and n stacks to be deposited at opposite ends of the substrate in addition to the interleaved layers at the center. Simple ohmic contacts to the p and n ends enabled the electroabsorption characteristics of the central area to be measured for light travelling perpendicular to the junction planes. Only a few volts produced significant changes in absorption at wavelength from 1.2 to 1.3  $\mu\text{m}$ , in agreement with theory. (Author abstract) 14 refs.

Greene, P.D. (STC Technology Ltd, Harlow, Engl); Wheeler, S.A. *J Cryst Growth* v 84 n 2 Aug 1987 p 259-265.

**094605 CADMIUM DOPING OF  $\text{InP}$  GROWN BY MOCVD.** The use of Cd as a p-type dopant during the growth of  $\text{InP}$  by metalorganic chemical vapor deposition (MOCVD) has been investigated. Trimethylindium, phosphine and dimethylcadmium (DMCd) were used as sources of In, P and Cd, respectively. The effect of the DMCd flow rate and the reactor pressure on the  $\text{InP}$  doping level was determined. The concentration of Cd in the  $\text{InP}$  was found to be proportional to its partial pressure in the reactor and the deposition rate was independent of the total reactor pressure. These results are in agreement with theoretical considerations. Deterioration of the layer morphology was observed for depositions at low reactor pressure and high DMCd flow rate. The results demonstrate that Cd is not a suitable dopant for low pressure MOCVD for high p-type doping levels. (Author abstract) 9 refs.

Blaauw, C. (Bell-Northern Research, Ottawa, Ont, Can); Emmerstorfer, B.; SpringThorpe, A.J. *J Cryst Growth* v 84 n 3 Sep 1987 p 431-435.

**094606 GROWTH OF THIN  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$  LAYERS BY LIQUID PHASE EPITAXY.** The growth rate of thin ( $< 100 \text{ nm}$ )  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$  layers by step-cooled liquid phase epitaxy (LPE) is reported. Growth from  $\text{In-Ga-As}$  melts at approximately  $600^\circ\text{C}$  is shown to require growth times under one second to obtain layers less than 150 nm thick. In contrast adding the isoelectronic dopant aluminum to growth melt significantly reduces the observed growth rate, and layer thicknesses below 30 nm can be obtained for growth times on the

order of one second. Aluminum isoelectronic doping is therefore considered an important method for obtaining thin layers of  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$  by LPE. (Author abstract) 8 refs.

Whitney, Peter S. (MIT, Cambridge, MA, USA); Fomstad, Clifton G. *J Cryst Growth* v 84 n 4 Oct 1987 p 676-678.

**094607 MOCVD GROWTH OF  $\text{InP}$  ON 4-INCH SI SUBSTRATE WITH  $\text{GaAs}$  INTERMEDIATE LAYER.** This letter describes the heteroepitaxy of  $\text{InP}$  on Si by MOCVD. A new epitaxial structure with a thin  $\text{GaAs}$  intermediate layer ( $\text{InP}/\text{GaAs}/\text{Si}$ ) is proposed to alleviate the large lattice mismatch (8.4%) between  $\text{InP}$  and Si. Using this structure, a 4-inch  $\text{InP}$  single crystal with a mirror-like surface and good thickness uniformity ( $\Delta d/d = \pm 10\%$ ) was obtained. Residual stress in the  $\text{InP}$  film was  $5.7 \times 10^8 \text{ dyn/cm}^2$  for the  $\text{InP}/\text{GaAs}/\text{Si}$  structure, as compared to  $8.3 \times 10^8 \text{ dyn/cm}^2$  for the  $\text{InP}$  directly grown on Si. This shows that the  $\text{GaAs}$  intermediate layer is also effective in reducing the residual stress in the  $\text{InP}$  epilayer. (Author abstract) 9 refs.

**094608 STRAIN-INDUCED SHIFT OF OPTICAL PHONON FREQUENCY IN  $\text{InGaP}$  LAYERS GROWN ON  $\text{GaAs}$  SUBSTRATES.** Raman spectra from  $\text{InGaP}$  epitaxial layers grown on  $\text{GaAs}$  (001) and (111)B substrates were studied. Both LO and TO phonon frequencies varied, not only with the alloy composition, but also with the lattice strain induced by the lattice mismatch between the epitaxial layer and the substrate. The amounts of these frequency variations agreed with the calculations, including a two-dimensional elastic strain in the epitaxial layer. (Author abstract) 21 refs.

**094609 INTERMIXING PROCESS OF  $\text{InGaAs}/\text{InP}$  MQW GROWN BY METALORGANIC MOLECULAR BEAM EPITAXY AT THERMAL ANNEALING.** The intermixing process of  $\text{InGaAs}/\text{InP}$  multiple-quantum-well (MQW) structure by thermal annealing at  $500\text{--}700^\circ\text{C}$  is investigated. Optical measurement appears to show that the MQW structure is unstable in the annealing above  $700^\circ\text{C}$ . SIMS and X-ray analysis, however, reveal that the MQW structure remains basically intact and that this intermixing process is mainly attributable to a minor diffusion of P atoms inducing a lattice-mismatched layer. The pronounced optical peak shifts can be roughly explained on the basis of this minor diffusion process. (Author abstract) 12 refs.

**094610 LOCAL ATOMIC ARRANGEMENT IN AN  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$  QUASI-BINARY ALLOY GROWN BY LIQUID-PHASE EPITAXY.** Weak diffuse scattering was observed in the small-angle scattering region from the  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$  alloy, which is theoretically found to originate from an atomic configuration on the group III sublattice. The experimental results could be explained in terms of the existence of a short-range ordered configuration. Such a deviation from the randomness was limited in terms of the volume of a unit cell, but no long-range order correlation was observed. (Author abstract) 6 refs.

**094611 LARGE SCALE SYNTHESIS AND GROWTH OF POLYCRYSTALLINE  $\text{InP}$ .** An apparatus has been designed and constructed for the direct synthesis and growth of polycrystalline indium phosphide by injection of phosphorus through a layer of boron oxide

into indium. Two modes of operation were used. In the first, the whole charge was frozen out slowly to form a crucible-shaped ingot which was broken up for use in single crystal growth. A seed crystal was used to present supercooling of the melt. In the second, the seed crystal was used to initiate Czochralski growth and the product was removed as a polycrystalline ingot. Details are given of the design features of the apparatus. The electrical properties of the product are presented, as well as analytical results obtained by spark source mass spectrograph. (Author abstract) 6 refs.

**094612 EPITAXIAL GROWTH OF MANGANESE-DOPED INDIUM PHOSPHIDE.** The successful preparation of iron-doped semi-insulating  $\text{InP}$  by organometallic vapor-phase epitaxy (OMVPE) has been recently reported. In this letter we report the preparation and characterization of manganese-doped  $\text{InP}$  OMVPE using an organometallic manganese source. Hall effect and photoluminescence measurements were used to assess the electrical and optical properties of the epitaxial layers. The grown layers were p-type and had carrier concentrations in the range  $7 \times 10^{14}$  to  $2 \times 10^{16} \text{ cm}^{-3}$ . 11 refs.

**094613 HETEROEPITAXIAL GROWTH OF  $\text{InP}$  ON GARNET.** In small areas  $\text{InP}$  has epitaxially been grown by organometallic vapor phase epitaxy on a synthetically grown lattice-adapted garnet substrate. Two one-dimensional lattice-matching relations have to be fulfilled. A high-resolution transmission electron micrograph shows that a somewhat inclined (001)  $\text{InP}$  surface is grown on a (111) garnet substrate in agreement with the matching relations. (Author abstract) 6 refs.

**094614 X-RAY CHARACTERIZATION OF  $\text{In}_x\text{Ga}_{1-x}\text{As}/\text{GaAs}$  QUANTUM WELLS.** X-ray diffraction patterns have been measured for pseudomorphic  $\text{In}_x\text{Ga}_{1-x}\text{As}/\text{GaAs}$  quantum well (QW) structures of widths 183, 121 and 61 Å, and composition x of about 0.28 grown by molecular beam epitaxy. The measured patterns show Pendellosung fringes due to the 513 Å  $\text{GaAs}$  barriers. These Pendellosung fringes are modulated by a broad weak peak mostly coming from the 183 Å  $\text{In}_x\text{Ga}_{1-x}\text{As}$  well layer. The X-ray diffraction fringe modulating patterns between  $32^\circ$  and  $33^\circ$  are fairly symmetric for a non-interrupted growth procedure. The diffraction pattern for the same structures with interrupted growth is less symmetric, since there is further modulation by another weaker peak. Layer thickness and In composition in thin layers (around 100 Å in the thickness) can be estimated by X-ray modeling and good agreement obtained between the measured and the calculated X-ray diffraction patterns. (Edited author abstract) 10 refs.

**094615 LPE GROWTH OF  $\text{InP}/\text{InGaAsP}/\text{InGaAs}/\text{InP}$  HETEROSTRUCTURE AT NORMAL COOLING RATE AT  $630^\circ\text{C}$ .** LPE growth conditions for  $\text{InGaAsP}/\text{InP}$  DH structures (approx.  $1.6 \mu\text{m}$ ) on (100)  $\text{InP}$  at  $630^\circ\text{C}$  are discussed.  $\text{InGaAsP}$  anti-meltback layers should be of  $\lambda \geq 1.3 \mu\text{m}$  for the active layers of  $\lambda = 1.6\text{--}1.66 \mu\text{m}$ . Control of the magnitude of the supersaturation of the melt for the anti-meltback layers and the upper cladding layers is very important in order to achieve the

meltback-free LPE growth. For the  $\lambda = 1.66 \mu\text{m}$  InGaAs active layer, it is also important to prevent circumferential dissolution of active layers. (Author abstract) 12 refs.

**094616 GROWTH AND CHARACTERIZATION OF LARGE SIZE, HIGH QUALITY,  $\text{InP}$  SINGLE CRYSTALS.** Single-crystal InP wafers grown by both the vertical gradient freeze (VGF) technique and the liquid encapsulated Czochralski (LEC) have been studied and compared in terms of overall quality. The techniques used to characterize the defect structure consist of (i) defect-revealing etch, (ii) transmission x-ray topography (TXRT), and (iii) transmission cathodoluminescence (TCL). Subsequent to etching, the VGF substrates were found to have a uniformly low ( $<100/\text{cm}^2$ ) EPD from the wafer edge to the center with no slip observed. The low defect density is independent of the sulfur doping level in the range  $2 \times 10^{17}$ – $3 \times 10^{18}/\text{cm}^3$  and is attributed to the reduced axial and radial temperature gradients during growth. In contrast, the Sn- and Fe-doped LEC material had overall EPD levels exceeding  $10^4/\text{cm}^2$ . (Edited author abstract) 13 refs.

**094617 USE OF TERTIARYBUTYLPHOSPHINE FOR THE GROWTH OF  $\text{InP}$  AND  $\text{GaAs}_{1-x}\text{P}_x$ .** A newly-developed phosphorus source, tertiarybutylphosphine (TBP), which is much less toxic than  $\text{PH}_3$ , has been used to grow InP and  $\text{GaAs}_{1-x}\text{P}_x$  by atmospheric pressure organometallic vapor phase epitaxy (MOVPE). Excellent morphologies are obtained for the growth of InP between 560 and  $630^\circ\text{C}$  for TBP partial pressures larger than  $0.5 \times 10^{-3}$ . For the first time, V/III ratios as low as 3 have been used to grow InP epilayers with featureless morphologies at  $600^\circ\text{C}$ . The use of TBP to replace  $\text{PH}_3$  in the growth of  $\text{GaAs}_{1-x}\text{P}_x$  results in a nearly linear relationship between vapor and solid composition at  $610^\circ\text{C}$ , i.e., the P distribution coefficient is nearly unity. This contrasts sharply with the very low P distribution coefficient obtained using  $\text{PH}_3$  at such low growth temperatures. (Edited author abstract) 29 refs.

**094618 HIGH-PURITY LPE GROWTH OF  $\text{InP}$  BY CO ADDITION TO AN  $\text{In-P}$  MELT.** High-purity InP layers are grown using an LPE technique with Co addition. In an In-P solution, Co combines with P to form a CoP precipitate. Solution impurities were removed by incorporation into the CoP precipitate and the In-P solution was purified as a result. High-purity InP layers with  $100,000$ – $110,000 \text{ cm}^2/\text{Vs}$  of Hall mobility at 77 K were obtained by a combination of adding the Co and baking the In-P solution in wet hydrogen. (Author abstract) 14 refs.

**094619 COMPARATIVE STUDY ON PROTECTION METHODS AGAINST  $\text{InP}$  SUBSTRATE DECOMPOSITION IN LIQUID PHASE EPITAXY.** The use of a Sn-In-P melt and of InP cover wafers of different orientations to prevent thermal surface decomposition of InP substrates in liquid phase epitaxy has been compared. An almost equivalent protection efficiency was found for the Sn-In-P solution and a (111B) wafer. However, with the melt approach a remarkable increase of residual impurity density was observed particularly at the interface of epitaxial InGaAs layers. (Author abstract) 5 refs.

Pfanner, K. (Heinrich-Hertz-Inst fuer Nachrichtentechnik Berlin GmbH, Berlin, West Ger); Franke, D.; Sartorius, B.; Schlak, M. *J Cryst Growth* v 88 n 1 Apr 1988 p 67-70.

**094620 CRACKS IN  $\text{InP}$ -BASED HETEROSTRUCTURES.** InGaAs/InP and InAlAs/InP single heterostructure grown by molecular beam epitaxy and InGaAsP/InP single heterostructures grown by liquid phase epitaxy under large negative lattice mismatch conditions have been investigated in order to clarify the physical mechanisms of crack formation and propagation. It has been found that cracks generated at the epilayer-substrate interface propagate into both the epilayer and the substrate. It has been observed that cracks parallel to the  $[11\bar{0}]$  direction have a higher mobility than cracks parallel to the  $[110]$  direction. The previously reported cracking model, involving glide, combination and lock up of misfit dislocations, has been confirmed. (Author abstract) 19 refs.

**094621 DIFFUSION-LIMITED GPE GROWTH OF MIXED CRYSTALS: APPLICATION TO  $\text{In}_{1-x}\text{Ga}_x\text{As}$  ON  $\text{InP}$ .** It is shown that for LPE at constant temperature in an  $(n+1)$  component system the layer thickness is proportional to  $\sqrt{t}$  and the solid composition is constant irrespective of the magnitude of the  $n^2$  diffusion coefficients  $D_{ij}$ . For a ternary system the crystallization path is determined by the ratio of the effective diffusion coefficients of the two dissolved components  $D_2/D_3$ . Growth experiments of the InGaAs lattice-matched to InP at  $600^\circ\text{C}$  prove the  $\sqrt{t}$  law. The crystallization path is derived by measuring the solid composition as a function of supersaturation. An analysis using the phase diagram in clouding strain energy yields  $D_{\text{Ga}}/D_{\text{As}} = 0.42$ . The effective diffusion coefficients of As and Ga in In are obtained. (Edited author abstract) 23 refs.

**094622 ELECTRICAL AND OPTICAL PROPERTIES OF  $\text{InP}$  GROWN BY MBE USING  $\text{P}^+$  ION BEAM.** InP layers have been grown on Fe-doped semi-insulating InP substrates by molecular beam epitaxy using a low energy  $\text{P}^+$  ion beam under various conditions: V/III flux ratios were from 1.2 to 2.2, and growth temperatures were from 400 to  $490^\circ\text{C}$ . The electrical and optical properties of the epilayers are described. The unintentionally doped epilayers were n-type, and there existed two shallow donor levels with activation energies of 4 and 7 meV and two deep donor levels with activation energies of 125 and 175 meV. The carrier concentration and mobility increased with decreasing V/III flux ratio and/or increasing power temperature. The carrier concentration and mobility measured at 80 K were  $1.2 \times 10^{16} \text{ cm}^{-3}$  and  $21200 \text{ cm}^2/\text{Vs}$  for the sample grown at  $490^\circ\text{C}$  and with a V/III flux ratio of 1.9. Photoluminescence spectra and SIMS profiles showed that Fe atoms diffuse into epilayers from substrates and pile up near the surface. (Author abstract) 8 refs.

Morishita, Y. (Mitsubishi Electric Corp, Amagasaki, Jpn); Maruno, S.; Ito, T.; Nomura, Y.; Ogata, H. *J Cryst Growth* v 88 n 2 Apr II 1988 p 215-220.

**094623 LPE GROWTH OF  $\text{GeDOPED InGaAsP/InP}$  BY TWO-PHASE SOLUTION TECHNIQUE.** Germanium doping of  $\text{In}_{1-x}\text{Ga}_x\text{As}_y\text{P}_{1-y}$  ( $E_g \approx 0.95 \text{ eV}$ ) layers grown by LPE using two-phase solution technique produces n-type layers with distribution coefficient  $k_{\text{Ge}} \approx 4.5 \times 10^{-3}$ . In addition, Ge doping gives rise to a new band of luminescence. The experiments are carried out in a horizontal sliding boat system by using a two-phase solution technique in which an excess piece of undoped InP is kept floating on the growth solution. In most cases, the as-grown layers are smooth and shiny. At times, a clean wipe off does not occur and a metallic solution cover is found on the growth substrate at the end of the growth run. **094624 EFFECT OF LATTICE MISMATCH BETWEEN EPITAXIAL LAYER AND SUBSTRATE ON IMMISCIBILITY OF  $\text{InGaAsP/GaAs}$  LPE LAYERS.** The liquid phase epitaxy (LPE) growth of InGaAsP on GaAs in the immiscible region has been studied in terms of the substrate induced stabilization. The results show that layers grown on (100) GaAs exhibit extraordinary behavior in the PL spectra as well as the surface morphology, while those on (111)A and (111)B GaAs do not. This suggests that the stabilization due to the substrate for the (111) orientation is stronger than that for (100), which is consistent with the theoretical prediction that the effect of strain energy induced by the substrate is greater for the growth on (111) than (100) oriented substrates. It is suggested, by examining the compositional variation at the onset of the LPE growth, that the effect which weakens the substrate induced stabilization for the (100) orientation is the presence of defects due to the lattice mismatch between the substrate and the transient layer, that grows within the initial short time of about 50 ms. (Author abstract) 35 refs.

**094625 METAL ORGANIC VAPOUR PHASE EPITAXY (MOVPE) OF HIGH PURITY  $\text{InP}$  AND THE ROLE OF RESIDUAL IMPURITIES.** InP epitaxial layers have been grown using an atmospheric pressure, metal-organic vapor phase epitaxy (MOVPE) reactor and various trimethylindium sources purified by different routes and analyzed by inductively coupled plasma emission spectrometry (ICP) and different phosphine sources. The inadvertent incorporation of residual impurities Zn and Si has been studied by electrical methods and photoluminescence (PL). The effect of growth temperature, V/III ratio, and growth rate is reported. High purity InP with  $n_{77\text{K}} < 3 \times 10^{14} \text{ cm}^{-3}$  and  $\mu_{77\text{K}} > 110,000 \text{ cm}^2/\text{Vs}$  has been prepared from the purest trimethyl indium and 100% phosphine sources at a temperature of  $600^\circ\text{C}$  and a V/III ratio of 34/1. This material also shows good surface morphology and the optical spectra are dominated by excitonic, near-band gap emissions at low temperatures. The Zn and Si impurities have a dramatic effect on the electrical and photoluminescence properties, lowering the carrier mobility and introducing deep centers associated with bound donors (Si) and acceptors (Zn, C). (Author abstract) 39 refs.

Gerrard, Neil D. (UMIST, Manchester, Engl); Nicholas, D. Julian; Williams, John O.; Jones, Anthony C. *Chemtronics* v 3 n 1 Mar 1988 p 17-30.

**094626 DEVELOPMENT OF LOW DISLOCATION  $\text{InP}$  SINGLE CRYSTALS DOPED SIMULTANEOUSLY WITH Ga AND As.** InP single crystals with low dislocation were developed using an improved LEC technique and simultaneous doping of Ga and As. Amounts smaller than  $10^{19}$ – $10^{20} \text{ cm}^{-3}$  of Ga and As in the melted material were sufficient to reduce the EPD of both N-type crystal doped with Sn and semi-insulating crystal doped with Fe to less than  $1000 \text{ cm}^{-2}$ . Doping of Ga and As had no influence on the electrical properties and IR absorption. The deviation of lattice parameter was less than  $4 \times 10^{-4}$  and no misfit dislocation was observed in the epitaxial layer. These crystals are expected to be used for the manufacture of OE-IC and other devices and further the development of such devices. (Author abstract) 5 refs.

**094627 EFFECT OF GROWTH TEMPERATURE ON  $\text{InGaAsP/GaAsP}$  EPITAXIAL GROWTH.** The epitaxial growth condition of InGaAsP on  $\text{GaAs}_{0.61}\text{P}_{0.39}$  is discussed in conjunction with a lattice latching effect

which is shown to have a relationship with the solid composition of the epilayer. The growth temperature dependence of this relation is also discussed in terms of a theoretical calculation. The PL FWHMs of the epilayers depend on the solid composition but not on the growth temperature. This behavior is attributed to the compositional fluctuation, lattice latching effect and binodal instability of the epilayers. (Author abstract) 27 refs.

**094628 SIMULATION AND GROWTH RATE UNIFORMITY OF MOVPE INP USING ADDUCTS.** InP was grown by MOVPE using phosphine and the adduct TMIIn-TEP. Growth rate and uniformity were measured for different growth conditions and reactor geometries, and were compared to finite difference computer simulations. Good agreement was found between experimental and simulated growth uniformity, except when gas phase depletion reactions occurred. These reactions are usually thought to be eliminated by the use of indium-adducts, but in this paper we demonstrate that these reactions still occur under certain growth conditions. Growth rate simulations were compared to experimental data to detect the onset of depletion reaction effects, and to find means to eliminate them. Simulations were also used to improve reaction chamber design for growth uniformity. (Author abstract) 25 refs.

**094630 SOLID COMPOSITION OF  $\text{In}_{1-x}\text{Ga}_x\text{As}$  GROWN BY THE HALOGEN TRANSPORT ATOMIC LAYER EPITAXY.** The growth of  $\text{In}_{1-x}\text{Ga}_x\text{As}$  by halogen transport atomic layer epitaxy (ALE) is described. The vapor-solid distribution relation for the group III elements is experimentally obtained. A model which assumes the Langmuir-type adsorption for the group III monochlorides is developed. It is shown that the solid composition grown by halogen transport ALE is determined by the competitive adsorption of GaCl and InCl on the substrate. (Author abstract). 16 Refs.

**094631 HIGH QUALITY SINGLE CRYSTAL GROWTH OF LAYERED InSe SEMICONDUCTOR BY BRIDGMAN TECHNIQUE.** This paper concerns layered crystals of InSe semiconductor grown using the Bridgman technique from a nonstoichiometric melt of  $\text{In}_{0.52}\text{Se}_{0.48}$ . The segregation of excess In decreased by decreasing the temperature gradient of the solid-liquid interface and a good quality InSe single crystal could be grown in a temperature gradient as low as  $4^\circ\text{C}/\text{cm}$ . The value of electron mobility and photoluminescence spectra were greatly improved in comparison with the previously reported data. (Author abstract). 11 Refs.

**094632 COMPOSITIONAL GRADIENTS IN InGaAs - A GROWTH MODEL AND THE ELECTRICAL EFFECTS ON PHOTODETECTORS.** PIN de-

vices have been grown by vapor phase epitaxy in which the InGaAs layer has either a depth compositional gradient, as determined by X-ray diffractometry, or in which the InGaAs layers exhibit no depth compositional gradient. The electrical properties of these devices have been measured. While the devices with ungraded InGaAs layers show a strong dependence of the dark current on the lattice mismatch (versus the underlying substrate), the devices with depth gradients in the InGaAs layer exhibit low dark currents (less than 10 nA) over a wide range of heterojunction mismatch conditions. We propose a model for the growth of the InGaAs layer which both accounts for the presence of the depth gradient and presents a scheme for growing depth-uniform (ungraded) material. We then extend this model to explain the differing electrical properties of devices with and without depth compositional gradients. (Author abstract). 12 Refs.

**094633 GROWTH OF IRON DOPED SEMI-INSULATING INP BY HYDRIDE VAPOR PHASE EPITAXY IN A NITROGEN AMBIENT.** The hydride vapor phase epitaxial (VPE) growth of semi-insulating (SI) InP:Fe using  $\text{N}_2$  as a carrier gas is reported. Iron doping was achieved by using  $\text{FeCl}_2$  generated in situ by reaction of HCl and powdered iron in a  $\text{N}_2$  carrier, and the transport of iron as  $\text{FeCl}_2$  was verified by optical absorption spectroscopy. In order to achieve InP growth in a  $\text{N}_2$  carrier input flowrates were adjusted to minimize the pyrolysis of  $\text{PH}_3$ . The thermodynamics of  $\text{FeCl}_2$  transport and InP growth in an inert carrier are discussed, and preliminary results showing the growth of  $10^8 \Omega \text{ cm}$  InP: Fe using this technique are presented. (Author abstract). 12 Refs.

Karlcek, R.F. Jr. (AT&T Bell Lab, Murray Hill, NJ, USA). *J Cryst Growth* v 91 n 1-2 Aug 1988 p 33-38.

**094634 INCLUSION-LIKE DEFECTS IN INP SUBSTRATES AND RELATED DEFECTS IN HETERO-EPI-TAXIAL AND ZN DIFFUSED LAYERS.** InP substrates grown by the liquid encapsulated Czochralski technique often contain typical inclusion-like defects which consist of a central core from which dislocation loops are punched out. The correlation between these defects present in InP substrates and the crystal quality of InGaAsP and InGaAs epilayers and Zn diffused InP layers has been studied. It has been found that the InGaAsP layers grown by liquid phase epitaxy exhibit roughly circular large hillocks, up to  $100 \mu\text{m}$  in diam, related to the inclusion-like defects. The propagation of dislocation loops from the substrate into the epilayers has been demonstrated. As for InGaAs layers grown by the molecular beam epitaxy, defects elongated in the [110] direction, up to  $50 \mu\text{m}$  in length and  $100 \mu\text{m}$  in width, have been observed to be in a one-to-one correspondence with the inclusion-like defects. Misfit dislocations within both InGaAs/ InP and InGaAsP/InP heterostructures and cracks within Zn diffused InP layers have been found to originate preferentially at the inclusion-like defects. (Edited author abstract). 12 Refs.

Franzosi, P. (CNR, Parma, Italy); Salvati, G.; Scaffardi, M. *J Cryst Growth* v 91 n 1-2 Aug 1988 p 90-96.

**094635 DESIGN OF THE OPTIMUM REACTOR CHAMBER FOR UNIFORM INP EPILAYER THICKNESS PROFILES GROWN BY MOVPE.** Gas flow control tubes were designed to obtain uniform epitaxial layers grown by metalorganic vapor phase epitaxy (MOVPE). Four tube-shape parameters for the reactor, the angle of inclination of the susceptor, the angle of inclination of the top wall of the tube, and the curvature and height of the top wall were varied and the uniformity of the InP epitaxial layers was studied. The inclined susceptor and inclined top wall improved the thickness uniformity in the direction of the gas flow. It was also found that the curvature of the top wall of the tube was effective in the control of the epitaxial layer thickness in the direction normal to the gas flow. Uniform epitaxial layers over entire 5 cm diam wafers could be obtained by

optimizing the design of the tube. (Edited author abstract). 10 Refs.

**094636 MASS SPECTROMETRIC STUDIES OF PHOSPHINE PYROLYSIS AND OMVPE GROWTH OF InP.** The mechanism of  $\text{PH}_3$  decomposition was studied by using  $\text{D}_2$  as a carrier gas and analyzing the reaction products with a mass spectrometer. The effects of InP and silica surfaces were investigated. The only gaseous product below  $600^\circ\text{C}$  is  $\text{H}_2$ . Since any gas phase H atoms would produce HD, the reaction occurs entirely on the surface. The slow step is the unimolecular removal of the first hydrogen atom, with an activation energy of  $36.0 \text{ kcal/mole}$  on InP surfaces. The reaction on InP is first order for  $\text{PH}_3$  concentrations as high as 15%, so the surface is not saturated at those conditions. When trimethylindium (TMIIn) is added to the gas mixture, the mechanism changes dramatically, probably proceeding via an unstable intermediate adduct of TMIIn and  $\text{PH}_3$  which eliminates  $\text{CH}_4$  upon formation. This concerted reaction lowers the pyrolysis temperatures of both  $\text{PH}_3$  and TMIIn. (Author abstract) 28 refs.

## Hardening

**094637 SOLUTION HARDENING DUE TO A NONRANDOM ATOM ARRANGEMENT IN III-V TERNARY ALLOY SEMICONDUCTORS.** Nonrandomness in the atomic arrangement impedes the motion of a dislocation. The extra resolved shear stress to move a dislocation,  $\tau$ , is calculated for III-V ternary alloy semiconductors on the basis of a thermodynamical analysis where the strain energy is considered as the mixing enthalpy. The  $\tau$  is large for a large lattice-mismatched alloy, e.g., InGaAs while negligible for a closely lattice-matched alloy, e.g., GaAlAs. The hardening in the alloy with the strain due to lattice mismatch can be significant at high temperatures or during the operation of devices and thus could elongate the device lifetime. (Author abstract) 13 refs.

## Heat Treatment

**094638 RAMAN STUDY OF DISORDER IN LASER-ANNEALED III-V SEMICONDUCTORS.** From Raman study of laser-annealed InP and GaAs semiconductors (both crystalline and ion implanted), the conclusion is drawn that under certain conditions a disordered polycrystalline phase rather than a monocrystalline one may be produced. The diagnostic of the disorder is based on the Raman polarization measurements as well as on phonon linewidths and frequency shifts and on plasmon-phonon damping. Calculations were performed on the ratios of phonon scattering intensities for a polycrystal with either random or preferential orientation of crystallites. The dependence of Raman line shape on crystallite size is evaluated. From comparison of calculated and measured data the degree of orientation and size is estimated. (Author abstract) 16 refs.

Reshina, I.I. (Acad of Sciences of the USSR, Leningrad, USSR). *Phys Status Solidi A* v 106 n 1 Mar 1988 p 261-270.

**094639 COMPUTER ANALYSIS OF EFFECTS OF ANNEALING ON  $\text{InP}$  INSULATOR-SEMICONDUCTOR INTERFACE PROPERTIES USING MIS C-V CURVES.** The effects of annealing on the distributions of interface states at the I-S interface were investigated by analyzing the C-V characteristics of as-grown and annealed  $\text{Al}_2\text{O}_3/\text{native oxide}/\text{InP}$  MIS capacitors using a self-consistent computer simulation program. It is shown that interface states form a continuum of donor-like and acceptor-like states continuously distributed both in energy and in space. The state density distribution before and after annealing maintains the same functional form, which is U-shaped in energy and exponentially decaying in space. The charge neutrality point dividing donor-like and acceptor-like states occurs at the U-shaped minimum. Annealing reduces the spatial extension of states, the U-shape curvature and the magnitude of density. However, the energy position of the charge neutrality point remains remarkably invariant. (Author abstract) 31 refs.

## Impurities

**094640 ACCEPTOR LEVELS IN INDIUM SELENIDE. AN INVESTIGATION BY MEANS OF THE HALL EFFECT, DEEP-LEVEL-TRANSIENT SPECTROSCOPY AND PHOTOLUMINESCENCE.** Acceptor levels related to I, II, IV and V group impurities in indium selenide are studied by means of the Hall effect, deep-level-transient spectroscopy (DLTS) and photoluminescence. Activation energies for hole concentrations in the range from 200 to 300 MeV have been measured. A reversible change of sign of the Hall voltage has been observed below 215 K. This behavior can be explained through a model in which acceptor levels are assumed to be shallow and interlayer planar precipitates of ionized shallow donors create potential wells that behave as deep donors and in which a low concentration of bidimensional free electrons can exist. This model also explains the capacitance-voltage characteristics of both  $\text{ITO}/\text{p-InSe}$  and  $\text{Au}/\text{p-InSe}$  barriers. A broad band whose intensity is related to p conductivity appears in the PL spectra of low resistivity p-InSe. The shape and temperature dependence of this band can be explained through self-activated photoluminescence in a complex center. (Edited author abstract) 40 refs.

**094641 DIFFUSION MECHANISM OF Cd IN  $\text{InP}$  AND  $\text{InGaAs}$ .** Cadmium was diffused into  $\text{InP}$  and  $\text{InGaAs}$  using  $\text{Cd}_3\text{P}_2+\text{P}$  or  $\text{Cd}_3\text{P}_2+\text{Cd}_3\text{As}_2$  as the diffusion sources. Two diffusion fronts were observed. The diffusion characteristics for  $\text{Cd}_3\text{P}_2+\text{P}$  sources are interpreted based on the interstitial-substitutional model, or its modification, the vacancy complex model. The charge state of the diffusing interstitial cadmium atom is a singly ionized donor. The chemical species of phosphorus which reacts with  $\text{InP}$  is  $\text{P}_2$  and gaseous Cd originates from solid-phase  $\text{CdP}_2$ . For  $\text{Cd}_3\text{P}_2+\text{Cd}_3\text{As}_2$  diffusion sources, the effective diffusion coefficient and the surface acceptor concentration decrease with increasing the  $\text{Cd}_3\text{As}_2$  weight fraction. The relative depth of the deeper diffusion front becomes more deep when the supply of vacancies is suppressed. (Author abstract) 13 refs.

**094642 CALCULATION OF DISLOCATION PINNING FORCES IN  $\text{InP}$  WITH ISOVALENT IMPURITIES BY SOLID SOLUTION HARDENING MODEL.** Based on a solid solution hardening model, the authors have considered the solution of isovalent impurities in  $\text{InP}$  and the elastic misfit arising from the differences of the tetrahedral radii between added impurities and host atoms. For isovalent impurities in  $\text{InP}$ ,

pinning forces as large as  $10^9 - 10^{10}$  dynes/cm<sup>2</sup> have been calculated. Thus, the reduction in dislocation density in  $\text{InP}$  single crystals doped with isovalent impurities can be explained. (Author abstract) 15 refs. In Chinese.

**094643 TIN-RELATED SHALLOW DONOR IN INDIUM SELENIDE.** Hall-effect measurements in indium selenide samples doped with different amounts of tin are reported. The temperature dependence of free-electron concentration is interpreted through a single-donor single-acceptor model from which the ionization energy of the tin related shallow donor (22 meV) and the compensation ratio are obtained. At low temperature the electron concentration departs from activated behavior and tends to be constant. This can be interpreted through the existence of two-dimensional subbands related to interlayer planar aggregates of donor impurities that are located in energy below the tin-related donor level. (Author abstract) 15 refs.

Mari, B. (Univ of Valencia, Valencia, Spain); Segura, A.; Chevy, A. *Appl Phys A* v A46 n 2 Jun 1988 p 125-129.

**094644 NATURE OF THE ELECTRICAL INACTIVITY OF TIN AND IRON IMPURITY ATOMS IN  $\text{In}_2\text{Te}_3$  AND  $\text{Ga}_2\text{Te}_3$ .**  $\alpha\text{-In}_2\text{Te}_3$ ,  $\beta\text{-In}_2\text{Te}_3$ , and  $\text{Ga}_2\text{Te}_3$  crystals doped with iron or tin were studied. Iron and tin are found in divalent states in  $\beta\text{-In}_2\text{Te}_3$  and  $\text{Ga}_2\text{Te}_3$  by Moessbauer spectroscopy. Their electrical inactivity is explained by a compensation effect of  $\text{In}^+$  or  $\text{Ga}^+$  ions which pins the Fermi level to the middle of the energy gap. In  $\alpha\text{-In}_2\text{Te}_3$  doped with iron or tin some impurity enriched regions which results in additional conductivity at low temperature are found. (Author abstract) 13 Refs.

**094645 PHOTOLUMINESCENCE ENHANCEMENT OF  $\text{InP}$  TREATED WITH ACTIVATED HYDROGEN.** A large enhancement of the photoluminescence intensity emitted by a (100)-oriented  $\text{InP}$  surface after exposure to activated hydrogen, indicating a sharp reduction of the surface recombination rate, is reported in this work. It is shown, using capacitance-voltage measurements performed on metal-insulator-semiconductor structures, that the hydrogen treatment also results in a strong pinning of the interface Fermi level. These phenomena are interpreted on the following basis: (i) neutralization by hydrogen species of active recombination centers which are deemed to be phosphorus-dangling bonds; and (ii) creation of pinning surface states due to the formation of volatile phosphorus hydride compounds freeing excess indium atoms. (Edited author abstract) 28 refs.

Viktorovitch, P. (CNRS, Ecully, Fr); Benyahia, F.; Santinelli, C.; Blanchet, R.; Leyral, P.; Garrigues, M. *Appl Surf Sci* (1985) v 31 n 3 Apr 1988 p 317-326.

**094646 LOCALIZED VIBRATIONAL MODES IN PROTON AND DEUTERON IMPLANTED  $\text{InP}$  SINGLE CRYSTALS.** Infrared absorption spectra of proton and deuteron implanted  $\text{InP}$  single crystals exhibit four localized vibrational modes with frequencies of 2197, 2212, 2308, 2335  $\text{cm}^{-1}$  and 1600, 1619, 1659, 1678  $\text{cm}^{-1}$ , respectively. From a comparison of these mode frequencies with those in other species containing In-H(D) and P-H(D) bonds it is concluded that all four modes observed are due to stretching vibrations of bonds formed between phosphorus and the implanted atoms. The number of vibrating bonds is found to be proportional to the damage density. Annealing experiments indicate a higher thermal stability of the defect configurations giving rise to the two high-energy localized modes. (Author abstract) 14 refs.

## Low Temperature Effects

**094651 VARIABLE-RANGE HOPPING IN  $\text{InP}$  CLOSE TO THE METAL-INSULATOR TRANSITION.** Analysis of conductivity data taken over the temperature range 4.2-0.05 K for a compensated sample of  $\text{InP}$  on the insulating side of, but very close to, the metal-insulator transition in terms of the relation  $\sigma = \sigma_0 \exp[-(T_0/T)^s]$  gives  $s=0.25$  instead of  $s=0.5$  previously obtained for a sample at some distance from the transition. Application of a small magnetic field produces behavior characteristic of the metallic regime and so confirms the phase diagram proposed by Shapiro. (Author abstract) 6 refs.

Finlayson, D.M. (St. Andrews Univ, St. Andrews, Scotl); Mason, P.J.; Mohammad, I.F. *J Phys C Solid State Phys* v 20 n 25 Sep 10 1987 p L607-L610.

**094652 THERMAL EXPANSION COEFFICIENT AND GRUNEISEN PARAMETER OF INP CRYSTAL AT LOW TEMPERATURES.** The thermal expansion of the lattice constant of InP crystal has been measured in the range 4.2–300 K by the Bond method and the results are shown graphically. The thermal expansion coefficient  $\alpha$  calculated from the experimental results is negative between 15 and 80 K and positive below 15 K. The corresponding Gruneisen parameter  $\gamma$  closely follows the behaviour of  $\alpha$  and the values of  $\alpha$  and  $\gamma$  are tabulated and shown graphically. The results do not agree with the phenomenological theory in which only a negative  $\alpha$  is predicted for InP at low temperatures. (Author abstract) 13 refs.

**Magnetic Field Effects** See Also SEMICONDUCTOR DEVICES—Tunneling.

**094654 SHALLOW DONOR-LIKE IMPURITY STATES.** We present evidence of hydrogenic behavior of shallow donor-like impurity states in n-type InP ( $8.5 \times 10^{15} \text{ cm}^{-3} < N_d - N_a < 6.2 \times 10^{16} \text{ cm}^{-3}$ ) from magnetic freeze out experiments at magnetic fields up to 18 T. This occurs at  $T < 10$  K and at a magnetic field sufficiently high to induce a metal-insulator transition. At high fields, the reduction of the binding energy with respect to the hydrogenic model of D.M. Larsen can be well accounted for by the increasing overlap of the impurity wave functions as the donor concentration increases. (Author abstract) 18 refs.

Aulombard, R.L. (CNRS, Montpellier, Fr); Kadri, A.; Zitouni, K.; Konczewicz, L. *Solid State Commun* v 61 n 7 Feb 1987 p 419-422.

**094655 MAGNETOPHONON EFFECT IN N-InSb UNDER HYDROSTATIC PRESSURE.** The magnetophonon effect in nondegenerate N-InSb is investigated under hydrostatic pressure in the magnetic field up to 0.7 T at liquid nitrogen temperature. The magnetophonon oscillation in the Hall voltage for N-InSb under hydrostatic pressure is reported here for the first time. The experimental results and theoretical analysis show that both oscillations for the Hall coefficient and transverse magnetoresistance have a similar relationship with pressure, i.e., the periods of oscillation decrease with the increase of the pressure, which shows the similar physical mechanism, i.e., increase of the energy gap with increasing pressure. (Author abstract) 19 refs.

## Magnetic Properties

**094656 THE TWO-PHOTON MAGNETOABSORPTION IN n-InSb.** By measuring the photoconductivity (pc) and modulated pc, two-photon magnetoabsorption (TPMA) excited by a cw CO<sub>2</sub> laser in n-InSb at  $T = 15$  K in the Voigt configuration and magnetic field in  $<111>$  orientation up to 4.2 T was observed. The experimental results show that the TPMA process in InSb could be explained by the 'interband-intraband' transition

theory. Most of the absorptions observed are proved to be spherical transitions, while the remainders are induced from weaker inversion asymmetry transition, warping or K<sub>H</sub> transitions. TPMA coefficients are derived by calculating the imaginary part of the third nonlinear susceptibility. By comparing these coefficients with the changes in pc induced by TPMA the current TPMA theory is confirmed. (Edited author abstract). 13 Refs. In Chinese.

## Measurements

**094657 PHOTO HALL MEASUREMENTS OF BAND-TAIL ABSORPTION AND RECOMBINATION TIMES IN INDIUM ANTIMIDE.** Photo Hall measurements are reported for a n-type InSb sample at 77 K. A bulk recombination time of 350 ns and an effective surface recombination time of 20 ns, corresponding to a surface recombination velocity of  $2.8 \times 10^5 \text{ cm s}^{-1}$ , has been estimated from an analysis of the frequency dependence of the photocurrent generation. The measurements yield interband absorption coefficients in the band-tail which are systematically lower than the previous optical measurements, being up to an order of magnitude lower at  $100 \text{ cm}^{-1}$  below the band edge. The form of the band-tail is qualitatively described in terms of the convolution of an exponential edge and an acceptor impurity resonance. (Author abstract) 12 refs.

**094658 FAR-INFRARED MAGNETOOPTICAL ABSORPTION IN  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$ .** By observing far-infrared electron cyclotron resonance in photoexcited  $\text{In}_x\text{Ga}_{1-x}\text{As}$  ( $x = 0.53$ ) at 4.2 K, as well as the Zeeman absorption signal due to donor electrons, the electron transfer between the conduction band and donor states is investigated. Impact ionization of donor electrons by photoexcited electrons has been confirmed. From the time-resolved measurement, the apparent lifetime of conduction electrons is found to be  $17 \mu\text{s}$  and the momentum relaxation time  $6.7 \times 10^{-13} \text{ s}$ . The time-resolved absorption measurement gives a definite clue to the electron capture rate by a donor and the recombination rate at an acceptor center. (Author abstract) 9 refs.

**Mechanical Properties** See Also SEMICONDUCTING GALLIUM COMPOUNDS—Mechanical Properties.

**094659 MICROHARDNESS OF  $\text{CuInSe}_2$ .** Vickers microhardness measurements have been performed on (112) faces of n- and p-type  $\text{CuInSe}_2$  single crystals at room temperature. In nearly stoichiometric samples, hardness values of  $2.33 \pm 0.06 \text{ GPa}$  and  $3.37 \pm 0.09 \text{ GPa}$  were found for n- and p-type material respectively. Preliminary results regarding hardness anisotropy and microhardness changes due to larger deviations from stoichiometry are given. At applied loads in the range 5–500 g no dependence of the microhardness on the load was found. (Author abstract) 20 refs.

## Microscopic Examination

**094660 LATTICE POSITION OF DIFFUSED Zn IN InP.** We have measured the substitutional fraction ( $f_s$ ) for Zn atoms diffused into InP crystals using the proton-induced X-ray excitation (PIXE) technique. Diffusion times ranged from 15–60 min at 425–650°C. For several samples with diffusion depths in the range 0.75–3.7  $\mu\text{m}$  (as determined by SIMS analysis), we find that the Zn impurity atoms reside almost totally on lattice sites:  $f_s = 0.9 \pm 0.1$ . Contrary to results of an earlier study, we find

no evidence for precipitates in the diffused layers. However, only approx.  $10^{-3}$ – $10^{-1}$  of the Zn is electrically active, consistent with Tuck and Hooper's suggestion of neutral  $V_P\text{Zn}_{1/2}V_P$  complexes. (Author abstract) 10 refs.

**094662 TRANSMISSION/SCANNING TRANSMISSION ELECTRON MICROSCOPY INVESTIGATION OF Au/Cr CONTACTS TO P-TYPE InP.** The change in contact resistance produced by the annealing of Au/Cr metallizations to p-type InP has been correlated with the microstructural changes examined by electron microscopy. The contacts were initially non-ohmic. Their resistance decreased, but remained non-ohmic, even after annealing to temperatures up to 450°C. Transmission and scanning transmission electron microscopy of cross-section samples revealed the formation, at elevated temperatures, of CrP and AuIn intermetallic layers at the contact/semiconductor interface. Chromium appeared to initiate compound formation through the dissociation of InP, although gold likely assisted in driving the reactions. CrP formed first, at temperatures below 350°C, as a polycrystalline, fine-grained layer between the Cr and InP. The formation of islands of AuIn followed at about 400°C and these grew into a continuous layer upon further annealing. (Author abstract) 14 refs.

## Microstructure

**094663 AVERAGE BOND LENGTHS AND ATOM ARRANGEMENT IN  $\text{In}_{1-x}\text{Ga}_x\text{As}$  AND  $\text{GaAs}_{1-x}\text{P}_x$  III-V TERNARY ALLOY SEMICONDUCTORS.** Statistics for five different tetrahedra in  $\text{In}_{1-x}\text{Ga}_x\text{As}$  and  $\text{GaAs}_{1-x}\text{P}_x$  III-V ternary alloy semiconductors were derived through a thermodynamical analysis. Every bond length between nearest-neighbor atoms in each tetrahedron was calculated. Then, average bond lengths were obtained theoretically; they agree fairly well with experimental data from the extended X-ray absorption fine structure. Effects of the short-range order in atom arrangement on the average bond lengths were discussed. (Author abstract) 15 refs.

## Modification

**094664 SPECTROELLIPSOMETRIC STUDY OF THE ELECTROCHEMICAL MODIFICATION OF InP.** In the cathodic decomposition of InP, which occurs during hydrogen evolution, an indium rich film grows on the surface of the semiconductor. Subsequently this film undergoes transformations between oxidized and reduced forms following the electrode polarization. An in situ spectroellipsometric study of these transformations was carried out. From these measurements it is possible to obtain both the thickness and the dielectric function of the film. Using the effective medium approximation, the components of the two forms of film are identified: indium oxide and solution in the oxidized stage, indium and solution in the reduced one. These results show that spectroellipsometry is a method well suited to characterize

in situ the electrochemical surface modifications. (Author abstract) 14 refs.

**094665 ELECTRONIC BAND STRUCTURE AND OPTICAL ANISOTROPY IN InS: I. EXPERIMENTAL STUDY.** Optical properties of InS on (001) surfaces are investigated using polarized absorptions near the fundamental gap (1.5 to 3.0 eV) and polarized reflectivity in the range of photon energy from 2 to 20 eV using a synchrotron radiation source. Detailed analyses of polarized absorption spectra reveal that the fundamental band gap of InS is an allowed indirect transition for each polarization in the (001) plane. The lowest direct-gap is allowed for b-polarization, but forbidden for a-polarization. Dielectric functions are derived from reflectivity spectra by Kramers-Kronig analysis and some features in spectra are assigned to interband transitions. (Author abstract) 17 refs.

**094666 EXTRINSIC PHOTOLUMINESCENCE FROM InGa/GaAs PSEUDOMORPHIC SINGLE QUANTUM WELLS.** Extrinsic luminescence due to carbon and beryllium acceptors in InGaAs pseudomorphic single quantum wells has been studied. The relative intensity is found to be very weak, even for acceptor concentrations approximately  $10^{17} \text{ cm}^{-3}$ . Acceptor binding energies are obtained and compared with those for GaAs/AlGaAs quantum wells and InGaAs/GaAs multilayer structures. Despite the relatively large strains in the InGaAs/GaAs single quantum wells, we do not observe any significant effect on the binding energies. (Author abstract) 22 refs.

**094667 PHOTOLUMINESCENCE STUDIES ON THE LAYER SEMICONDUCTOR  $\text{In}_2\text{Se}_3$ .** Photoluminescence investigations of the layered  $\text{In}_2\text{Se}_3$  show clearly distinct results for two varieties of materials: pure  $\alpha$ - $\text{In}_2\text{Se}_3$  and mixture of  $\alpha$  and  $\gamma$ - $\text{In}_2\text{Se}_3$ . The pure  $\alpha$ - $\text{In}_2\text{Se}_3$  exhibits, at liquid helium temperature, two photoluminescence bands: one at higher energy 1.523 eV due to the radiative recombination of impurity bond excitons, and the other at lower energy 1.326 eV due to recombination on luminescence centers formed by intrinsic defects due to disorder in the cation sublattice. In the mixed  $\alpha$  and  $\gamma$ - $\text{In}_2\text{Se}_3$  only one broad band at 1.319 eV is observed related to the additional disorder in the cation sublattice coming from the alloying of the  $\alpha$ - and  $\gamma$ -phases. (Author abstract) 9 refs.

**094671 OPTICAL PROPERTIES OF InS UNDER HIGH PRESSURE.** Pressure effects are studied on the fundamental indirect gap, direct gap, and next highest critical point in InS single crystals by using a diamond-anvil cell for the first time. A synchronized decrease of their energies is observed with pressure increasing up to 2 GPa. This unusual behavior is inferred partly due to a softening of In-In bond under pressure. (Edited author abstract) 12 refs.

Takarabe, K. (Okayama Univ of Science, Okayama, Jpn). *Phys Status Solidi B* v 145 n 1 Jan 1988 p 219-225.

**094672 EFFECTS OF HEAT TREATMENT ON THE OPTICAL AND STRUCTURAL PROPERTIES OF InSe THIN FILMS.** Thin films of indium selenide of different thicknesses were deposited on glass substrates by vacuum evaporation. The optical gaps were determined from the absorption spectra. The value increases with the thickness of the films and heat treatment temperature. The variation of valence band density of states with temperature is observed. A radial distribution function analysis of X-ray diffraction spectra is made to get an insight into structural information. A transition from the amorphous to the crystalline state takes place at 573 K. (Edited author abstract) 28 refs.

**094674 TIME RESOLVED PHOTOLUMINESCENCE FROM  $\text{Yb}^{3+}$  CENTERS IN InP:Yb.** The time dependence of the internal 4f-4f transitions of  $\text{Yb}^{3+}$  in InP has been studied as a function of temperature over the

range 10 to 110K. The quenching of both the photoluminescence intensity and the excited state lifetime is found to be thermally activated with  $E_A \approx 0.1$  eV. This is interpreted in terms of hole emission from the neutral Yb acceptor. At low temperature the lifetime appears dominated by weak coupling to resonant states in the valence band, while nonexponential contributions to the decay are interpreted as being due to the capture of nonequilibrium carriers by the neutral Yb acceptor. (Author abstract) 18 refs.

Klein, P.B. (Naval Research Lab, Washington, DC, USA). *Solid State Commun* v 65 n 10 Mar 1988 p 1097-1101.

**094675 REACTIVELY EVAPORATED FILMS OF INDIUM SULPHIDE.**  $\alpha$ - $\text{In}_2\text{S}_3$  films were prepared by reactively evaporating indium in an atmosphere of sulphur. X-ray diffraction studies show that the grains have no preferred orientation on the substrate surface. Film properties (surface smoothness, optical transmission, and refractive index) are optimized in the substrate temperature interval (425  $\pm$  50)K. Fundamental absorption starts at (2.01  $\pm$  0.01)eV and the transition leading to this is a direct forbidden one. Charge carriers are n-type and the activation energy for electronic conduction is (0.26  $\pm$  0.02)eV. (Edited author abstract) 22 refs.

George, J. (Cochin Univ of Science & Technology, Cochin, India); Joseph, K.S.; Pradeep, B.; Palson, T.I. *Phys Status Solidi A* v 106 n 1 Mar 1988 p 123-131.

**094676 MAGNETO-OPTICAL INVESTIGATIONS ON P-InSb BICRYSTALS IN THE SUBMILLIMETER WAVELENGTH RANGE.** The magneto-optical properties of p-type InSb bicrystals are investigated from  $\lambda = 57$  to 251  $\mu\text{m}$  at temperatures  $T \leq 4.2$  K and magnetic fields up to  $B = 6.5$  T. At 118.8 and 251  $\mu\text{m}$  the cyclotron resonance of the conduction electrons in the n-inversion layer adjacent to the grain boundary can be detected. At all other wavelengths strong magnetic field dependent absorption effects in the p-type bulk mask the relatively small absorption effects in the inversion layer. The acceptor excitation spectrum of the bulk is discussed. From the periodicity of quantum oscillations three occupied electric subbands are identified. The experimental cyclotron resonance spectra are modeled as the superposition of three cyclotron resonance lines belonging to the three occupied electric subbands. Cyclotron masses are obtained and compared to the experimental data. (Edited author abstract) 20 refs.

**094677 RESONANT RAMAN SCATTERING OF Li INTERCALATED InSe.** Optical properties of  $\text{Li}_x\text{InSe}$  are presented as a function of the lithium concentration and temperature. Investigations of the photoluminescence and absorption measurements show that the presence of alternating sheets of lithium induces changes in the electronic band structure. The Raman spectrum does not change appreciatively unless it is modified by the presence of excitons near certain resonance conditions. (Author abstract) 7 refs.

Jouanne, M. (CNRS, Paris, Fr); Julien, C.; Beserman, R.; Balkanski, M. *Phys Scr* v 38 n 3 Sep 1988 p 471-473.

**094678 PICOSECOND  $\text{CO}_2$  LASER-INDUCED SELF-DEFOCUSING IN INSB.** Self-defocusing of 45-ps  $\text{CO}_2$ -laser pulses has been observed in InSb at intensities as low as 1 MW/cm<sup>2</sup>. It is caused by the two-photon absorption generated free carriers and the resulting self-phase modulation. In addition to demonstrating spatial beam modulation in this material at 10.6  $\mu\text{m}$ , the authors confirm directly that such a process occurs on a picosecond time scale. This suggests that the switching speed of infrared optical bistable devices can be increased to the picosecond regime. They also provide an

accurate determination of the two-photon absorption coefficient in InSb. Other applications to continuum and ultrashort pulse generation are discussed. 26 refs.

**094679 INVESTIGATIONS OF RECOMBINATION MECHANISMS IN THE PULSED FAR IN-FRA RED PHOTO RESPONSE OF n-InP.** Narrow (10-50 ns) far infrared pulses ( $\lambda = 91 \mu\text{m}$ ) with sharp ( $\geq 1$  ns) cut-off are used to probe the recombination dynamics of electrons in high purity n-InP. The decay of the photosignal is investigated for a variety of laser intensities, sample bias voltages, temperatures and compensation ratios. A simple model is outlined to explain the observed linear dependence at low bias of the inverse decay time parameter,  $\tau^{-1}$ , on electric field. For higher impurity samples at higher intensities the decay exhibits an initial fast component. A more complete model, invoking Auger recombination, is outlined to explain this effect. (Author abstract) 15 refs.

## Oxidation

**094681 KINETICS OF ANODIC OXIDE GROWTH.** The process of anodic oxide growth has been investigated. It is shown that the obtained experimental results confirm the Fehner-Mott oxidation model in the case of InSb, a typical compound of the III-V group. We also present a kinetic theory of the anion migration in the formed oxide. The theory is based on the following assumptions. (a) The only species which moves through the formed oxide is the OH<sup>-</sup> anion. (b) The chemical reactions of OH<sup>-</sup> with In<sup>3+</sup> and Sb<sup>3+</sup> cations take place simultaneously and independently, in a thin layer of the oxide/InSb interface. The resulting solution of the kinetic equations describes the anion distribution in the formed oxide. A simple expression for the rate of oxidation is obtained. Another possible application of the presented theory is suggested. (Author abstract) 10 refs.

Grinberg, S.P. (Tel-Aviv Univ, Ramat Aviv, Isr); Shapira, Yoram; Calahorra, Z. *Phil Mag Lett* v 55 n 6 Jun 1987 p 305-310.

**094682 NEW PLASMA OXIDATION OF InP FOR IGFET.** InP surfaces have been oxidized by reactive sputtering of InP target in a magnetically confined, dc excited, plasma of pure oxygen. Microprobe and Auger analyses have indicated a uniform composition with equal proportions of phosphorus and indium oxides. Measurement on MOS devices have shown a film resistivity of  $4.6 \times 10^{13} \Omega \cdot \text{cm}$  and minimum interface states density of  $1.2 \times 10^{12}/\text{cm}^2/\text{eV}$ . The MOSFET on p-InP has indicated an electron mobility of 400  $\text{cm}^2/\text{Vs}$  in the induced n-channel. (Author abstract) 30 refs.

## Phase Diagrams

**094683 THERMODYNAMICS AND KINETICS OF THE QUASIBINARY SYSTEM  $\text{Hg}_{(3-3k)}\text{In}_{2k}\text{Te}_3$ .** I. INVESTIGATIONS BY X-RAY DIFFRACTION AND DIFFERENTIAL THERMOANALYSIS. The phase diagram of the quasibinary system  $\text{Hg}_3\text{Te}_3\text{-In}_2\text{Te}_3$  was investigated by Guinier X-ray measurements and by DTA experiments. It is shown that at the stoichiometry  $\text{Hg}_5\text{In}_2\text{Te}_8$  an ordered phase is formed, which undergoes a phase transition at 720 K. There are indications that the high-temperature phase of  $\text{Hg}_5\text{In}_2\text{Te}_8$  has a structure with a partially ordered cation sublattice, but the miscibility gaps between the high-temperature phase and the regions with defect zincblende lattice could not be detected. At the stoichiometric composition  $\text{Hg}_3\text{In}_2\text{Te}_6$ , for temperatures higher than 625 K, a solid solution with the defect zincblende structure is formed, whereas at lower temperatures a decomposition into the two phases,  $\text{Hg}_5\text{In}_2\text{Te}_8$  and  $\text{HgI}_2\text{Te}_4$ , occurs. Several proposals for the structures of the ordered phases are developed. (Edited author abstract) 17 refs.

Leute, Volkmar (Univ Muenster, Muenster, West Ger); Schmidtke, Heinrich Michael. *J Phys Chem Solids* v 49 n 4 1988 p 409-420.

**094684 PHASE DIAGRAM OF  $\text{CuIn}(\text{S}_x\text{Te}_{1-x})_2$ .** The phase diagram of the system  $\text{CuIn}(\text{S}_x\text{Te}_{1-x})_2$  was obtained from differential thermal analysis (DTA) and X-ray diffraction measurements. DTA measurements were carried out on each sample and the transition temperatures were plotted as a function of alloy composition. A miscibility gap was found in a wide range of the system. Values of lattice parameters were determined in all cases and the limits of single phase solid solution were estimated. For the range of single phase behavior, values of energy gap were obtained by optical absorption measurements. (Author abstract) 9 refs.

## Phase Transitions

**094685 PHASE TRANSITION TEMPERATURE OF THE  $\alpha\text{-In}_2\text{Se}_3$  SINGLE CRYSTAL.** The variation of phase transition temperature was observed when the heating-cooling cycle of the stoichiometric  $\alpha\text{-In}_2\text{Se}_3$  single crystals was repeated under the vacuum of  $4 \times 10^{-5}$  torr. The critical temperature of  $\alpha \rightarrow \beta$ -phase transition decreased but the critical temperature of  $\beta \rightarrow \alpha$ -phase transition increased as the number of heating-cooling cycle increased. This phase transition temperature shift control can be understood when we consider the fact that the stoichiometric  $\alpha\text{-In}_2\text{Se}_3$  single crystal changes to the In-excess  $\alpha\text{-In}_2\text{Se}_3$  single crystal due to the evaporation of selenium atoms when the sample was in heating cycle. (Author abstract) 3 refs.

**094687 ELECTRONIC BAND STRUCTURE AND OPTICAL ANISOTROPY IN InS. II. THEORETICAL STUDY.** The electronic band structure of InS is calculated for the first time using the empirical pseudo-potential method. A group-theoretical study of the symmetry properties of InS is included. The resulting energy bands are then used to calculate the imaginary part of the dielectric function for each polarization along the principal axes of InS. The total and partial electronic densities are mapped on the (110) plane. Comparisons are made with previous experimental studies. (Author abstract) 19 refs.

Takarabe, K. (Okayama Univ of Science, Okayama, Jpn); Kawamura, H.; Wakamura, K. *Phys Status Solidi B* v 143 n 2 Oct 1987 p 519-538.

**094688 MULTIPHONON ABSORPTION IN InP.** IR absorption measurements have been made using a high resolution Fourier-transform spectrometer on crystals of InP in the region of  $(400-4000)\text{cm}^{-1}$  at temperature between 11-300 K. Very weak, new absorption bands, their absorption coefficients are of approx.  $10^{-1}\text{cm}^{-1}$ , were observed at  $996\text{cm}^{-1}$ ,  $965\text{cm}^{-1}$ ,  $932\text{cm}^{-1}$ ,  $838\text{cm}^{-1}$ ,  $776\text{cm}^{-1}$ ,  $742\text{cm}^{-1}$ ,  $718\text{cm}^{-1}$ ,  $590\text{cm}^{-1}$ ,  $558\text{cm}^{-1}$  and  $538\text{cm}^{-1}$ . The frequencies and temperature dependence of these weak bands indicate that they arise from three-phonon processes and appropriate assignments are given. We observed, using IR absorption technique, the boron contamination in LEC ( $\text{B}_2\text{O}_3$ )-CZ InP crystal. The content of boron contamination has been proved to be approx.  $10^{16}\text{cm}^{-3}$ . (Edited author abstract) 8 refs.

## Processing

**094689 SPECIAL FEATURES OF PULSED PHOTO ANNEALING OF INDIUM ANTIMONIDE.** The structure and morphology of the surface of indium antimonide subjected to ion implantation and annealing with a noncoherent light pulse emitted by xenon lamps were examined. The examination was carried out in an optical microscope, in a microinterferometer, and by transmission electron microscopy. The results show that at a light energy density of approximately  $17\text{J}/\text{cm}^2$ , local melting changes to uniform melting of the indium antimonide surface. The depth of penetration is approximately 20 nm. (Edited author abstract) 5 refs.

## Radiation Effects

**094692 A.C. HOPPING CONDUCTANCE IN ELECTRON-IRRADIATED InSb.** Sufficient degree of damage induced by electron irradiation in n-type InSb allows the observation of hopping conductance having a frequency dependence approximately  $\omega^2$  at low temperatures. The temperature dependence of  $s$  is studied and discussed in terms of quantum-mechanical tunnelling and the correlated barrier hopping mechanisms. (Author abstract) 19 refs.

## Reviews

**094694 DEVELOPMENT OF HIGH-QUALITY INP SINGLE CRYSTALS.** In the manufacture of electronic devices there is a need for crystals with low dislocation densities for both conductive and semi-insulating substrates. GaInAsP semiconductor lasers for optical communication at the 1.55  $\mu\text{m}$  band and GaInAs avalanche photodiodes (APDs) employing InP substrates have appeared on the market. To realize an optoelectronic integrated circuit (OEIC), the development of a semi-insulating substrate crystal has been started. An OEIC has transistors and optical devices integrated on the same wafer. A semi-insulating wafer is considered to be the most suitable substrate for an OEIC because of the easy isolation of its devices. Furthermore, as the thermal resistivity of InP is small (two-thirds that of GaAs), high power dissipation is permissible. If semi-insulating InP wafers are applied to transistors, the fabrication of a metal insulator semiconductor field effect transistor (MISFET) is possible. The chapter covers methods for crystal growth and reduction of dislocation density. 23 refs.

## Spectroscopic Analysis

**094695 FINE STRUCTURE IN THE FREE EXCITON REGION OF THE EMISSION SPECTRA OF  $\gamma$ -InSe.** The fine structure of the emission spectrum of  $\gamma$ -InSe in the free exciton region has been investigated. The complete behavior is given and the quantitative analysis is described in detail. Also, the doublet structure is examined and the possible stacking faults contribution is considered. It is found that the origin of the second peak is bound excitonic. The phonon modes involved in the temperature variation of the exciton energy are obtained from fitting the experimental data to previous theoretical calculations. An explanation is given for the temperature variation of the half width anomaly. (Author abstract) 16 refs.

**094697 VERIFICATION OF  $\text{CuInSe}_2$  DENSITY OF STATES FEATURES BY REFLECTION ELECTRON ENERGY LOSS SPECTROSCOPY.** Reflection electron energy loss measurements of  $\text{CuInSe}_2$  single crystals are reported and when possible, the losses are compared with previous results. Their identification of the transitions is confirmed and refined by spectrum simulations with total and partial densities of states from band structure calculations. New conduction-band maxima at energies not covered by the available calculations are proposed, and their consistency with the experimental loss energies is shown by another simulation with Lorentzian density peaks. (Edited author abstract) 26 refs.

**094698 PHOTOLUMINESCENCE SPECTRA OF LI-INTERCALATED INDIUM SELENIDE.** The photoluminescence (PL) spectra of pure and Li intercalated InSe using the n-butyl-lithium method are presented in the temperature range from 5 to 150 K and the effect of Li intercalation on the structure of the emission spectrum is examined. The new characteristics demonstrate the presence of new PL centers that modify the long-wavelength region of the spectrum. The observed modifications, which are analysed in detail, taking into account the dependence of the spectra on temperature optical excitation intensity and dose of intercalation, enable us to give an interpretation of their origin. (Author abstract) 18 Refs.

**094699 EFFECT OF LOCAL ATOMIC ARRANGEMENT ON Co-RELATED LUMINESCENCE IN III-V ALLOY SEMICONDUCTORS.** We have measured Co-related luminescence spectra of a series of  $\text{In}_{1-x}\text{Ga}_x\text{P}$  and  $\text{GaAs}_{1-x}\text{P}_x$  alloy semiconductors. The spectra show several broad bands and their intensities vary systematically with the change in alloy composition. These behaviors are well explained by the local atomic arrangements of each constituent atom surrounding the Co luminescent center, based upon the calculated occupation probability of the atoms. (Author abstract) 6 refs.

Conf on Lumin, Beijing, China, Aug 17-21 1987 p 409-410.

**094700 STUDIES OF InP SURFACE AND InP-INSULATOR INTERFACE BY SPECTRAL PHOTOLUMINESCENCE.** In this work, we use photoluminescence (PL) spectrum measurements (4 K and 77 K) as a means of assessing modifications of the surface properties of InP crystals subjected to various chemical treatments, insulating layer deposition and annealing. We show that all of the above processes strongly affect the photoluminescence spectrum of the InP surface (interface). We observed, in particular, important modifications of the intensity ratio (R) of two peaks located at 1.41 eV (P1) and 1.1 eV (P3). On the basis of a simple model we show that the PL spectrum provides direct information on (i) process induced modifications of the surface velocity and (ii) creation of new radiative centers which are probably related to lattice non-stoichiometry and which are responsible for the 1.1 eV transition. 3 refs.

**094701 PHOTOLUMINESCENCE CHARACTERIZATION OF RARE-EARTH (Er, Yb)-DOPED InP GROWN BY METALORGANIC CHEMICAL VAPOR DEPOSITION.** Er-doped and Yb-doped InP epitaxial crystals were grown by MOCVD and photoluminescence (PL) of intra-4f-shell transitions of the rare earth ions was observed. Rare-earth-ion-related PL intensities are observed to increase only sublinearly as a function of excitation photon density. Their decay time constants are about one order of magnitude smaller than those of corresponding rare earth ions in CdS. These results indicate that a strong nonradiative bimolecular decay mechanism is in effect in state-of-the-art crystals and that intra-4f-shell transitions of rare earth ions depend strongly on the host crystals in which the ions are incorporated. (Author abstract) 5 refs.

## Stability

**094702 MASS SPECTROMETRIC EVIDENCE OF INSTABILITY IN  $\text{In}_{1-x}\text{Ga}_x\text{As}$  COMPOUNDS: ACTIVITY MEASUREMENTS OF InAs.** Activity measurements in the  $\text{In}_{1-x}\text{Ga}_x\text{As}$  system are performed by mass spectrometry coupled with a multiple-Knudsen-cell furnace. The condition for reversible vaporization are first carefully analyzed as a function of the orifice to sample surface ratio, given the fact that the measurements of the partial pressure of Ga are doubtful, because equilibrium conditions are not established for this species in effusion cells. Activities of the InAs compound are deduced in the pseudo-binary section  $\text{In}_{1-x}\text{Ga}_x\text{As}$  from ionic intensities of  $\text{As}^{+2}$ ,  $\text{As}^{+4}$ , and  $\text{In}^{+}$ . The thermodynamic behavior of these solid solutions at 950 K shows an instable composition domain and consequently, at equilibrium, these mixtures present a miscibility gap. These thermodynamic results agree with all X-ray structure measurements showing that the usual elaborated compounds are homogeneous mixtures. Agreement between these data and previous calorimetric data is not good, and a lack of consistent thermodynamic data is still remaining for the GaAs-InAs pseudobinary system. (Author abstract) 36 Refs.

## Structure

**094704 ATOMIC STRUCTURE OF ORDERED InGaP CRYSTALS GROWN ON (001)GaAs SUBSTRATES BY METALORGANIC CHEMICAL VAPOR DEPOSITION.** InGaP crystals grown on (001)GaAs substrates by metalorganic chemical vapor deposition are structurally evaluated by transmission electron microscopy. High-resolution electron microscopy observation and electron diffraction analysis of both the (110) and the (11 $\bar{0}$ ) cross-section specimens strongly suggest that ordering of column III atoms on only two sets of the (111) planes with doubling in periodicity of (111) layers, i.e.,  $\text{In/Ga/In/Ga/In/Ga}$ , is occurring in the crystal. The ordering of the crystal is not perfect, and the ordered regions are assumed to be plate-like microdomains. (Author abstract) 18 refs.

**094705 InP (AND GaAs) SUBSTRATE STABILIZATION BY THE PRESENCE OF GaAs (AND InP) IN A METAL-ORGANIC VAPOUR-PHASE EPITAXY SYSTEM.** Metal-organic vapour-phase epitaxy (MOVPE) requires a stabilized substrate surface prior to growth to obtain a high-quality crystal. Here we show the effect of exposing GaAs and InP substrates to  $\text{AsH}_3$  and (or)  $\text{PH}_3$  in the temperature range from 550°C to 750°C, in an MOVPE reactor. The presence of a GaAs substrate partially stabilizes the InP substrate; the stabilized area decreases when either temperature of  $\text{AsH}_3$  flow increases. The presence of a stabilized InP substrate (under  $\text{PH}_3$  flow) also partially stabilizes the GaAs substrate. Surface analysis shows that the stabilized area contains column-V species coming from the neighbouring substrate. The V-hydride species active in the MOVPE environment are not dimers or tetramers. Annealing the substrates under both  $\text{AsH}_3$  and  $\text{PH}_3$  shows preference for As-species aggregation at the substrate surface. The simple model previously used to predict stabilization is extended to cover this mixed-hydride situation. (Edited author abstract) 17 refs.

**094710 X-RAY PHOTOELECTRON SPECTROSCOPY ANALYSIS OF CHANGES IN InP AND InGaAs SURFACES EXPOSED TO VARIOUS PLASMA ENVIRONMENTS.** InP and InGaAs electronic devices are subject to deterioration of their properties upon exposure to air, moisture, and irradiation due to the instability of their surfaces. Attempts to protect device surfaces by overcoating them with a plasma deposited protective coating are frustrated by a marked deterioration of their electrical properties after deposition. Using x-ray photoelectron spectroscopy, we have examined InP and InGaAs surfaces exposed to hydrogen, nitrous oxide, nitrogen, and ammonia plasma. We observed that these surfaces change substantially upon plasma exposure to either oxygen or hydrogen containing plasmas. The observed changes qualitatively agree with the observed device electrical property changes. (Author abstract) 24 refs.

ton, NJ, USA); Kaganowicz, G.; Robinson, J.W. *J Electrochem Soc* v 135 n 5 May 1988 p 1201-1206.

**094711 STABILISATION D'UNE SURFACE INP (100) PAR L'AZOTE OU PAR L'ANTIMOINE.** [Stabilization of an InP (100) Surface Using Nitrogen or Antimony]. For indium phosphide (InP), conventional cleaning procedures such as argon ion bombardment or vacuum annealing lead to the formation of metallic indium in the top layers. This negative effect may be reduced or balanced using special treatments based on the interaction of the surface with (V) elements closely related to phosphorus. In this AES-ELS study, some results are reported about the interaction of InP (100) with nitrogen ions and antimony atoms. From an initial surface including the usual contamination layer, bombardment of the sample with nitrogen ions of 300 eV energy induces the removal of carbon impurity; implantation of nitrogen in the top layers is simultaneously observed. At increasing N<sup>+</sup> dose, metallic In is detected in connection with etching effects on the surface oxide and on the N-implanted layer previously formed. Heat treatments of the InP sample with the presence of evaporated antimony atoms lead to the formation of In-Sb bonds, preventing the development of metallic In. Metallic Sb is not observed for the low coverages involved in the experiment. These results are deduced from the comparison of the AES-ELS spectra with those of pure In, Sb and InSb samples. (Author abstract) 6 refs. In French.

Bouslama, M. (Univ Claude Bernard Lyon I, Villeurbanne, Fr); Jardin, C. *Vide Couches Minces* v 43 n 241 Mar-Apr 1988, 2emes Journ Etud sur L'Epitaxie et la Passivation des Composés III - V, Fr, Apr 27-28 1988 p 221-222.

**094712 INTERACTION DE L'OXYGENE AVEC InP PASSIVE PHOSPHORE: PREMIERS RESULTATS SUR LE ROLE D'UNE COUCHE INTERFACIALE D'Yb.** [Interaction of Oxygen with Passivated Phosphorus: Preliminary Results on the Role of Interfacial Yb Film]. The interaction of molecular oxygen with the phosphorus passivated (100) face of InP (denoted InP(P<sub>2</sub>)) has been studied using Auger electron spectroscopy (AES) and ultraviolet photoelectron spectroscopy (UPS). It is shown that the 2 or 3 N.L. of phosphorus in excess on the surface almost inhibit any reaction with O<sub>2</sub> up to 10<sup>12</sup> L (1 L = 10<sup>-6</sup> T.s.). This is tentatively associated to a dense interconnected network of phosphorus. In an attempt to stimulate the O<sub>2</sub>-InP(P<sub>2</sub>) interaction, a layer of Yb has been evaporated before the O<sub>2</sub> exposure. The preliminary results show a dramatic increase of the oxygen adsorption for related structures observable at exposures as low as 60 L. (Author abstract) 7 refs. In French.

Tardy, J. (CNRS, Villeurbanne, Fr). *Vide Couches Minces* v 43 n 241 Mar-Apr 1988, 2emes Journ Etud sur L'Epitaxie et la Passivation des Composés III - V, Fr, Apr 27-28 1988 p 235-236.

**094713 SUR LES MODIFICATIONS DES PROPRIETES STRUCTURALES, MORPHOLOGIQUES ET ELECTRONIQUES DE InP (110) INDUITES PAR LE CHAUFFAGE.** [On the Modification of Structural, Morphological, and Electronic Properties of InP (110) by Annealing]. In this paper the authors present results obtained by A.E.S., L.E.E.D., and work function measurements on the modifications induced by annealing InP (110) cleaved surfaces. When increasing the temperature (up to 800 K), the L.E.E.D. diagram remains practically unaltered, while the Auger peaks and the work function rapidly changes. These last modifications are correlated and explained in terms of P vacancies. (Author abstract) 5 refs. In French.

Dumas, M. (CNRS, Montpellier, Fr); Benkacem, M.; Palau, J.M.; Lassabaterre, L. *Vide Couches Minces* v 43 n 241 Mar-Apr 1988, 2emes Journ Etud sur L'Epitaxie et la Passivation des Composés III - V, Fr, Apr 27-28 1988 p 241-244.

**094714 CHARACTERISATION DE L'INTERFACE InP-OXYDE ANODIQUE PAR UNE NOUVELLE TECHNIQUE DE MESURE DE CHARGES TRANSITOIRES.** [Characterization of the InP-Anodic Oxide Interface by a Novel Transient Charge Measurement Technique]. A new transient characterization technique is used to measure the surface potential shift, interface state density  $D_{it}$ , and state kinetics for n-InP MIS diodes with a double layer insulator (native anodic oxide-evaporated alumina). The surface Fermi level shift is limited at  $0.35 \pm 0.55$  eV from the conduction band by a steep increase of  $D_{it}$ . It is observed that this pinning level can be moved over 0.2 eV depending on the steady state bias conditions. This result can be explained by electrical-induced physical modifications of the interface in relation to phosphorous vacancy mobility. A secondary peak of states is observed close to the conduction band with a small capture cross section. (Edited author abstract) 4 refs. In French.

## Synthesis

**094715 PREPARATION AND SINGLE CRYSTAL INVESTIGATION ON THE INTERCALATION COMPOUND  $\text{In}_{0.67}\text{TaS}_2$ .** A vapor-phase transport technique yielded single crystals of the intercalation compound  $\text{In}_{0.67}\text{TaS}_2$  starting with  $2\text{H-TaS}_2$  and In. The title compound is hexagonal, space group  $P6_3/m2$ , with  $a=3.332(2)$ ,  $c=7.983(5)$  Å and  $Z=1$ . Using 293 K diffractometer intensity data, the crystal structure has been determined by a single-crystal X-ray technique and refined to a final  $R_w$  of 0.029. Although electron diffraction experiments did not reveal a clustering of the In atoms, their very large temperature factors indicate a positional disorder around the refined position in the trigonal-prismatic holes between the  $\text{TaS}_2$  layers. (Edited author abstract) 20 refs.

**Thin Films** See Also SOLAR ENERGY—Materials.

**094718 ELECTRICAL CHARACTERIZATION OF INDIUM TELLURIDE THIN FILMS.** The present

letter reports the growth of stoichiometric thin films of indium telluride and their electrical characterization. Stoichiometric films of indium telluride have been obtained by vacuum evaporation of a non-stoichiometric bulk compound with excess indium. The conductance resulting from the space-charge recombination process is proportional to the intrinsic carrier concentration and hence yields an activation energy equal to  $(E_g/2)$  and the conductance due to diffusion process being proportional to the square of the intrinsic carrier concentration yields an activation energy equal to  $E_g$ , the intrinsic band gap of the material. 7 refs.

Rousina, Roughieh (Sardar Patel Univ, Gujarat, India); Shivakumar, G.K. *J Mater Sci Lett* v 6 n 10 Oct 1987 p 1131-1132.

**094719 THERMAL DIFFUSIVITY MEASUREMENT OF MICRON-THICK SEMICONDUCTOR FILMS BY MIRAGE DETECTION.** We describe a method using the mirage detection technique for thermal diffusivity measurements of thin films. High frequency measurements are required for such materials. By determining the difference between two phase measurements, we have been able to avoid probe beam size effects which strongly affect the high frequency responses. The thermal diffusivity of a polycrystalline semiconductor thin film has been measured by using optical heating and compared with the corresponding single-crystal diffusivity. The thermal diffusivity of polymer semiconductor thin films has been obtained for various dopings by using electrical heating. (Author abstract) 20 refs.

**094720 FORMATION OF InSe AND GaSe DEPOSITED FILMS AND THEIR ELECTRICAL PROPERTIES.** The appropriate substrate temperatures for the formation of InSe and GaSe films by the evaporation of  $\text{In}_2\text{Se}_3$ , InSe,  $\text{Ga}_2\text{Se}_3$  and GaSe have been found. Epitaxial films of InSe were obtained by the evaporation of InSe on mica substrates whose temperature were kept at 400°C, whereas films of GaSe could not be formed on mica. The electrical properties of the InSe and GaSe films obtained are also reported. (Author abstract) 30 refs.

Yudasaka, M. (Yokohama Natl Univ, Yokohama, Jpn); Nakanishi, K. *Thin Solid Films* v 156 n 1 Jan 15 1988 p 145-152.

**094721 EFFECTS OF OXYGEN PARTIAL PRESSURE ON THE PROPERTIES OF REACTIVELY EVAPORATED THIN FILMS OF INDIUM OXIDE.** Thin films of indium oxide were prepared by evaporating indium in the presence of oxygen. The effects of varying the oxygen partial pressure on the optical, electrical and structural properties were investigated. Films evaporated under the optimum oxygen partial pressure of 0.133 Pa exhibited a resistivity of  $4.8 \times 10^{-4} \Omega \text{ cm}$  and a transmittance of more than 80% at wavelengths of 600 nm and above, for a film thickness of 225 nm. All the films, in the range of partial pressure of oxygen used, were found to be n type. The films showed a b.c.c. structure with  $a_0 = 1.0118$  nm and a preferred orientation along the  $\langle 400 \rangle$  axis. (Author abstract) 31 refs.

Naseem, S. (Univ of the Punjab, Lahore, Pak); Rauf, I.A.; Hussain, K.; Malik, N.A. *Thin Solid Films* v 156 n 1 Jan 15 1988 p 161-171.

**094722 PROPRIETES ELECTRIQUES DES COUCHES MINCES  $\text{D'In}_2\text{O}_3$  PREPAREES PAR OXYDATION POSTERIEURE DE METAL EVAPORE.** [Electric Properties of  $\text{In}_2\text{O}_3$  Thin Films Prepared by Post-Oxidation of the Evaporated Metal]. We studied the electrical properties of non-doped or tin-doped  $\text{In}_2\text{O}_3$  (ITO) thin films. The films were prepared by coevaporation of indium and tin in an  $\text{O}_2$  atmosphere of  $10^{-3}$  Torr, followed by post-oxidation of amorphous films of  $\text{InO}_x$  by heat treatment in air. Under optimum conditions of tin doping, an n-type semiconducting ITO film with resistivity  $\rho = (5-6) \times 10^{-4} \Omega \text{ cm}$  was

obtained. The films were highly degenerated, which allows us to postulate scattering of carrier electrons due to ionized impurities. (Author abstract) 23 refs. In French.

Noguchi, S. (Asahi Glass Co, Yokohama, Jpn); Sakata, H. *Thin Solid Films* v 157 n 2 Feb 29 1988 p 181-188.

**094723 GROWTH AND CHARACTERIZATION OF INDIUM TELLURIDE THIN FILMS.** Thin films of indium telluride prepared by conventional vacuum evaporation techniques are often non-stoichiometric because of fractionation. Hence, in an attempt to obtain stoichiometric films, non-stoichiometric bulk was used. It is observed that a bulk with a composition  $\text{In:Te} = 55.7:44.3$  (atomic per cent) yields stoichiometric films. The effect of deposition temperature and annealing at elevated temperatures has been studied in detail. The results indicate that an increase in the deposition temperature results in the re-evaporation of tellurium from the films whereas indium-deficient films are obtained on annealing at elevated temperatures. (Author abstract) 22 refs.

**094724 GROWTH AND CHARACTERIZATION OF  $\text{CuInSe}_2$  FILM BY CLOSE-SPACE EVAPORATION.**  $\text{CuInSe}_2$  thin films were prepared on mica substrates using an evaporation technique which involved varying the distance between the source and the substrate. Films evaporated on substrates at distances less than 1 cm from the source exhibited preferential orientation in the (112) direction. The grain size increased from 0.5 to 1.0  $\mu\text{m}$  as the source substrate distance decreased from 3 to 1 cm. The conductivity increased with a decrease in the distance between the source and substrate. Electron probe microanalysis of these films showed that films coated on substrates farther away from the source had a slight selenium deficiency and an excess of indium. Three characteristic energy gaps of 1.01, 1.25 and 2.4 eV were obtained from an analysis of the optical absorption spectrum. The optical transition probability for valence band to conduction band transitions was estimated to be 10.91 eV which gives an admixture of copper d states to the valence band of 32%. (Author abstract) 18 refs.

**094725 EFFECT OF POST-DEPOSITION VACUUM ANNEALING ON PROPERTIES OF ITO LAYERS.** Indium tin oxide (ITO) films have been deposited on glass substrates by dc reactive magnetron sputtering. The rectangular  $127 \times 336 \text{ mm}^2$  cathode target 90 percent In + 10 percent Sn was sputtered in an Ar +  $\text{O}_2$  gas mixture at a total pressure of 0.2 Pa. Post-deposition annealing of ITO-coated substrates at a temperature of about 500-700 K for some 70 min in vacuum at  $5 \times 10^{-3}$  Pa caused the layers to crystallize. The crystallization results in the ITO electric resistivity decreasing by more than five orders. After vacuum annealing ITO layers were obtained with a resistivity of about  $10^{-4} \Omega \text{ cm}$ . (Edited author abstract). 6 Refs.

**094726 EFFECT OF A TILTED MAGNETIC FIELD ON THE SIZE-QUANTIZED LEVELS OF QUANTUM WELLS IN ULTRATHIN FILMS OF NARROW-GAP SEMICONDUCTORS.** An attempt is made to investigate the effects of a tilted magnetic field on the size-quantized levels of quantum wells in ultrathin films of narrow-gap semiconductors, taking n-type InSb as an example. It is found that, in general, the energy eigenvalue of the lowest magneto-size-quantized level increases with increasing magnetic field and decreases both, with increasing film thickness and with increasing orientation of the magnetic field, for given values of the other parameters. Besides, it is observed that the difference of the energy

eigenvalues of the lowest two magnetic sub-levels of the lowest electric sub-band reaches a maximum at a given magnetic field, showing a decrease with its orientation, while it increases with the film thickness. (Author abstract). 17 refs.

Bose, M.K. (Univ Coll of Science & Technology, Calcutta, India); Majumdar, C.; Maity, A.B.; Chakravarti, A.N. *Phys Status Solidi B* v 148 n 1 Jul 1988 p 165-172.

**094727 PREPARATION OF EPITAXIAL InSb FILMS BY MAGNETRON SPUTTERING.** InSb demonstrates an extremely high electron mobility, up to 1 000 000  $\text{cm}^2 \cdot \text{V}^{-1} \cdot \text{s}^{-1}$  at 77 K, which makes it of particular interest for very high-speed circuit applications. The preparation of thin epitaxial films of InSb by magnetron sputtering is discussed. Using this technique, we have deposited good quality epitaxial InSb films on <100> InSb and <100> GaAs. The effects of substrate temperature and sputter pressure on film morphology, composition, and growth rate are examined. Preliminary measurement of the electrical characteristics of these layers and their crystal quality by X-ray diffraction and large-area electron-channelling pattern analysis are presented. (Edited author abstract) 12 refs.

**094728 INVESTIGATION OF ELECTRODEPOSITED CuInSe<sub>2</sub> FILMS.** After a brief review of CuInSe<sub>2</sub> films prepared using an electrophoretic technique, results obtained by an electrochemical deposition method will be described. The electrophoretic technique, which is simple, was first investigated and found to be unsuitable for CuInSe<sub>2</sub>-film deposition. Using the electrochemical deposition method, we obtained uniform and homogeneous CuInSe<sub>2</sub> films. The quality of the films was then determined by scanning electron microscopy, electron-probe microanalysis, X-ray diffraction, and secondary-ion mass spectroscopy. Heterojunction cells of the form CdS-CuInSe<sub>2</sub> were finally fabricated using the electrodeposited films. The devices showed an active-area AM1 short-circuit current density of more than 30  $\text{mA} \cdot \text{cm}^{-2}$  and a  $V_{oc}$  of about 0.2 V. (Author abstract) 4 refs.

**094729 GROWTH AND ANNEALING OF AgInSe<sub>2</sub> THIN FILMS.** Amorphous thin films of AgInSe<sub>2</sub> were grown by rf magnetron sputtering and then crystallized using two forms of optical annealing: laser annealing using a raster-scanned argon laser and heat-pulse annealing using a quartz-halogen heat-lamp system. It was determined that laser annealing of films on amorphous substrates resulted in fine-grained polycrystalline chalcopyrite AgInSe<sub>2</sub> thin films with a preferred (112) orientation. The presence of weak X-ray diffraction peaks associated with nonchalcopyrite phases indicated that some segregation had occurred. Heat-pulse annealing of films on single-crystal substrates led to better results. The films were more highly oriented with no evidence of any segregation. (Author abstract) 8 refs.

**094730 TRANSMISSION AND PHOTOREFLECTANCE SPECTRA IN HIGHLY STRAINED InGaAs-GaAs MULTIPLE QUANTUM WELLS.** Low temperature optical transmission spectra (TS) and room temperature photoreflectance (PR) spectra have been measured to investigate several  $\text{In}_x\text{Ga}_{1-x}\text{As}/\text{GaAs}$  strained multiple quantum wells (MQWs) grown by molecular beam epitaxy (MBE). Sharp PR features indicating excellent optical quality of these samples were observed. The excitonic transitions up to 3C-3H are observed. The band-to-band transitions are observed in

both TS and PR spectra, which are identified as 1C-1L transitions. The calculated transition energies, taking into account both the strain and the quantum well effects, are in good agreement with the TS and PR spectra. This shows that room temperature PR is a powerful and convenient tool to investigate the strained layer MQWs. A heavy-hole valence band discontinuity of 30% was obtained for  $0.13 \leq x \leq 0.193$ . We conclude that the light holes are in the GaAs barrier region (Type II MQWs) and the light hole transition 1C-1L is a sensitive parameter in determining the band offset in InGaAs/GaAs strained layer MQWs. (Edited author abstract) 21 refs.

Ji, G. (Univ of Illinois at Urbana-Champaign, Urbana, IL, USA); Reddy, U.K.; Huang, D.; Henderson, T.S.; Morokoc, H. *Superlattices Microstruct* v 3 n 5 1987, Third Int Conf on Superlattices, Microstruct and Microdevices, Chicago, IL, USA, Aug 17-20 1987 p 539-545.

**094731 REACTIVE SPUTTERED CuInSe<sub>2</sub>.** The deposition of CuInSe<sub>2</sub> thin films by co-sputtering from copper and indium planar magnetron sputtering sources in a working gas of argon plus  $\text{H}_2\text{Se}$  is being investigated. Near-stoichiometric coatings deposited onto glass and molybdenum-coated substrates have been found to have resistivities, Hall mobilities, absorption coefficients, band gaps, surface topographies, grain sizes and oxygen heat treatment behavior comparable with those of films produced by the more common three-source evaporation method. However, it has not been possible by reactive sputtering to deposit indium-rich films ( $[\text{In}]/[\text{Cu}] \approx 1.5$ ) of the type commonly used as a top layer in the preparation of two-layer device quality films by the evaporation method. Apparently an indium-rejection behavior, which occurs during the deposition process in  $\text{H}_2\text{Se}$  reactive sputtering, makes it difficult to achieve indium compositions beyond the amount that can be incorporated into the CuInSe<sub>2</sub> chalcopyrite phase. Experiments are described which were conducted to examine the dependence of the indium-rejection behavior on the deposition conditions. (Author abstract) 17 refs.

Thornton, John A. (Univ of Illinois, Urbana, IL, USA); Lomasson, T.C.; Talieh, H.; Tseng, B.-H. *Sol Cells* v 24 n 1-2 May-Jun 1988, Proc 8th Photovoltaic Adv Res Dev Proj Rev Meet, Denver, CO, USA, Nov 15-18 1987 p 1-9.

**094732 EFFECTS OF COMPOSITION AND SUBSTRATE TEMPERATURE ON THE ELECTROOPTICAL PROPERTIES OF THIN-FILM CuInSe<sub>2</sub> AND CuGaSe<sub>2</sub>.** Polycrystalline thin films of CuInSe<sub>2</sub> and CuGaSe<sub>2</sub> deposited by thermal evaporation onto heated substrates of 7059 glass and  $\text{Al}_2\text{O}_3$  were studied. The data for CuInSe<sub>2</sub> indicates an absorption coefficient as high as  $1.5 \times 10^5 \text{ cm}^{-1}$ , though predominantly  $(2.0-8.0) \times 10^4 \text{ cm}^{-1}$ , and band-gap values ranging from 0.94 to 1.02 eV, with band-gap narrowing observed for films deposited at 350°C. The effect of high temperatures and lower copper concentrations in CuInSe<sub>2</sub> and CuGaSe<sub>2</sub> is to shift the onset of absorption to higher energies. The data for CuGaSe<sub>2</sub> thin films indicate absorption coefficients up to  $(1-2) \times 10^5 \text{ cm}^{-1}$  at 500 nm and band gaps ranging from 1.66 to 1.72 eV. The effect of higher substrate temperatures on CuGaSe<sub>2</sub> is to eliminate secondary phases and minimize residual absorption below the band gap. The electrical measurements on CuInSe<sub>2</sub> indicate activated conductivity and show the films to be highly compensated by donors and acceptors whose origins are the native defects arising from non-stoichiometry. (Edited author abstract) 14 refs.

**094733 DEVICE QUALITY THIN FILMS OF CuInSe<sub>2</sub> BY A ONE-STEP ELECTRODEPOSITION PROCESS.** Fabrication of device quality polycrystalline thin films of CuInSe<sub>2</sub> with appreciable photovoltaic activity has been achieved by a simple one-step electrodeposition process from a single solution. Controlled by a personal computer, the thin film deposition process has been

upgraded to be semi-automatic with good accuracy, flexibility and reliability. The thin films are electrodeposited at constant potentials in unstirred solution. An innovative method employing a multi-potential procedure is used to produce the bilayer (indium-rich) thin films. Devices made from these films showed improved spectral response in the long wavelength region. The electron-beam-induced current measurement indicates a heterojunction device. (Edited author abstract) 16 refs.

## Transport Properties

**094734 DETERMINATION OF TRANSPORT PARAMETERS FOR InP DEVICE SIMULATIONS IN  $n^+nn^+$  STRUCTURES.** Phenomenological transport parameters in n-InP are derived from large scale, ensemble Monte Carlo particle simulations. These parameters are required in efficient numerical methods used to solve 'hydrodynamic-like' transport formulations which govern various physical models of bulk, unipolar InP devices. For an equivalent single-valley conduction band, a set of transport parameters in n-InP at 300 K is calculated from the Monte Carlo data. An example of the use of these parameters in a numerical simulation code is provided. (Author abstract) 7 refs.

## Vapor Deposition See Also LASERS, SEMICONDUCTOR—Fabrication.

**094735 EFFECT OF GAS PHASE GROWTH PARAMETERS ON THE COMPOSITION OF InGaAs IN THE HYDRIDE VPE PROCESS.** A 1.4  $\mu\text{m}$  thick InGaAs layer exhibiting an X-ray diffraction linewidth of 18 arc S has been grown on an InP substrate. This is the best crystalline perfection ever reported for InGaAs, as far as the author is aware. The effect of gas composition on lattice mismatch has been investigated for InGaAs layers grown under a variety of conditions. An empirical equation has been developed which relates lattice mismatch ( $\Delta a/a$ ) to metals ratio, mole fraction of  $\text{AsH}_3$  and mole fraction of HCl. Values of ( $\Delta a/a$ ) calculated using this equation are in good agreement with experiment. The metals ratio for lattice match is shown to vary linearly with the growth rate. This observation is shown to be consistent with mass transfer limitation in the gas phase. As a further consequence, relationships between layer thickness uniformity and lattice mismatch uniformity and between growth rate and gas composition are derived. (Author abstract) 18 refs.

Buckley, D.N. (AT&T Bell Lab, Murray Hill, NJ, USA). *J Electron Mater* v 17 n 1 Jan 1988 p 15-20.

**094736 LOW-VACUUM METALORGANIC VAPOR PHASE EPITAXY OF InGaP AND ITS IMMISCIBLE GROWTH.** InP and InGaP crystal growth on GaAs(100) was carried out by low-vacuum (0.03 Torr) MOVPE. Single crystals of InGaP were obtained on GaAs when the substrate temperature was 670°C. In this low-vacuum MOVPE growth of InGaP, as in conventional MOVPE, the growth rate is limited by the supply of group-III metalorganics, and Ga-element is taken into the grown layer more effectively than In-element. In some cases, immiscible InGaP growth was observed as a compositional separation in the grown layers when the substrate temperature was below 620°C. A model for the

crystal growth in low-vacuum MOVPE, which can explain the occurrence of the immiscibility, is proposed. (Author abstract). 27 Refs.

**094737 EQUILIBRIUM ANALYSIS OF THE VPE-HYDRIDE METHOD USING A GALLIUM-INDIUM ALLOY SOURCE.** Recently, a new and simple method was developed where the equilibrium expression can be used directly to analyze the VPE-hydride system with the two metal sources. This new method has been applied in study to the VPE-hydride technique with the alloy source. Results of the study explain the previously reported experimental data and predict that the composition of the ternary is not only dependent on the partial pressure of arsine and alloy composition but also on the partial pressure of HCl. The equilibrium analysis also indicates that the same alloy can continually be used in the VPE technique to produce the lattice-matched  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$ . 23 Refs.

## X-Ray Analysis

**094739 CHARACTERIZATION OF  $\text{In}_{1-x}\text{Ga}_x\text{As}_{1-x}\text{Sb}_x$  GaAs STRAINED LAYER SUPERLATTICES BY ION BACKSCATTERING-CHANNELING AND X-RAY DIFFRACTION.** The combination of ion backscattering and X-ray diffraction can be used to study composition, crystalline quality, and tetragonal distortion in strained layer superlattices (SLs). The authors investigated various  $\text{In}_x\text{Ga}_{1-x}\text{As}/\text{GaAs}$  SLs/MBE grown on GaAs(100) substrates using RBS/channeling, X-ray diffraction, and TEM techniques. The samples are composed of 2 to 20 nm thick layers with 10 to 40 periods and x-values of 18 to 24 percent. The epitaxial films were grown from Ga, In, and  $\text{As}_4$  fluxes. Initially, a 70 nm thick GaAs buffer layer with a perfect RHEED controlled surface was grown under optimal growth and thermal annealing conditions. In some cases an alloy buffer layer  $\text{In}_{0.5x}\text{Ga}_{1-0.5x}\text{As}$  was deposited. 12 Refs.

## SEMICONDUCTING INTERMETALLICS

### Magnetic Properties

**094740 HIGH-DENSITY PHOTOGENERATED FREE-CARRIER SPIN RELAXATION PROCESSES IN WURTZITE SEMICONDUCTORS:  $\text{CdSe}$  AND SEMIMAGNETIC SEMICONDUCTOR  $\text{Cd}_{1-x}\text{Mn}_x\text{Se}$ .** Picosecond time-resolved spin relaxation kinetics of high-density free carriers is investigated at low temperatures in  $\text{CdSe}$  ( $x = 0$ ) and in dilute semimagnetic semiconductor  $\text{Cd}_{1-x}\text{Mn}_x\text{Se}$  for  $x = 0.05$  and  $0.10$ . The

fast spin relaxation observed in  $\text{CdSe}$  results from a mechanism associated with the noncentrosymmetric character of the band structure for this material. This process is similar to the one proposed by M. I. D'yakonov and V. I. Perel' (1971) for the zinc blende crystal structures. The spin relaxation times in  $\text{CdSe}$  are on the order of 30 ps. The spin relaxation times are  $< 20$  ps in semimagnetic semiconductor  $\text{Cd}_{1-x}\text{Mn}_x\text{Se}$  and are consistent with spin-flip Raman scattering measurements. The increase in spin relaxation rate relative to  $\text{CdSe}$  is explained in terms of the carrier spin exchange between the carriers and the magnetic spin sites. A probable cause for the reduction in the observed spin polarization factor for carriers in  $\text{Cd}_{1-x}\text{Mn}_x\text{Se}$  ( $x \neq 0$ ) is presented. 42 refs.

### Structures

**094741 NEUTRON DIFFRACTION AND MAGNETIC ANISOTROPY STUDY OF Y-Fe-Ti INTERMETALLIC COMPOUNDS.** High resolution neutron powder diffraction has been used to determine the crystal structures of  $\text{YFe}_{11}\text{Ti}$  and  $\text{YFe}_{10}\text{Ti}$  intermetallic compounds. Both compounds crystallize in the  $\text{ThMn}_{12}$  tetragonal structure (space group  $I_4/mmm$ ). The 8j and 8f sites are virtually fully occupied by Fe whilst the 8i site is partially occupied by Fe and Ti atoms. The temperature dependence of the magnetic anisotropy from 293 to 78 K has been measured by the singular point detection technique. The magnetic anisotropy is found to increase with decreasing temperature. The value of the anisotropy field is 37 KOe and 21 KOe at 78 K and 293 K respectively. (Author abstract) 10 refs.

Moze, O. (Istituto MASPEC, Parma, Italy); Pareti, L.; Solzi, M.; David, W.I.F. *Solid State Commun* v 66 n 5 May 1988 p 465-469.

### Thin Films

**094742 ELECTRICAL TRANSPORT PROPERTIES OF THALLIUM-DOPED P-TYPE  $\text{Pb}_{0.8}\text{Sn}_{0.2}\text{Te}$  THIN FILMS.** Hall coefficient and d.c. conductivity studies were made on p-type  $\text{Pb}_{0.8}\text{Sn}_{0.2}\text{Te}$  thin films doped with different concentrations of thallium in the temperature range 77 to 500 K. The Hall coefficient and Hall mobility are found to decrease with an increase in the doping concentration of thallium. Hall coefficient data have been analysed in the light of a double valence-band model. Various band parameters such as valence band separation, population ratio, mobility ratio and effective mass ratio have been calculated. Hall mobility data have been analysed in the light of lattice- and defect-limited scattering mechanisms. (Author abstract) 33 refs.

Applications See LASERS, SEMICONDUCTOR—Fabrication.

Charge Carriers See Also RADIATION DETECTORS.

**094743 EFFECT OF REDUCTION OF PLZT ON CARRIER LIFETIME DETERMINED BY EBIC.** Lanthanum doped lead zirconate titanate (PLZT) behaves like an n-type semiconductor when reduced in vacuum. Steady state electron induced current was measured at different electron energies and lifetime of excess carriers was estimated at corresponding depths. The carrier lifetime decreased by one order of magnitude whereas the average sheet conduction increased by about four orders of magnitude due to reduction. (Author abstract) 11 refs.

Maurya, J.C. (Univ of Poona, Poona, India); Dixit, A.V.;

Manorama, Vardhreddy; Bhoraskar, S.V. *Solid State Commun* v 64 n 9 Dec 1987 p 1235-1240.

**094744 ACOUSTICAL DEFORMATION POTENTIAL AND EFFECTIVE MASS IN n-TYPE LEAD TELLURIDE BETWEEN 4 AND 300 K.** The acoustical deformation potential value is deduced for n-PbTe from low temperature electron mobility results. The value obtained is  $\Xi = (22 \pm 2)$  eV. Assuming  $\Xi$  independent of temperature T, the electron density of states effective mass at the conduction band edge follows the linear relation  $m^*(T) = 0.040 m_0 [1 + (4.7 \pm 0.3) \times 10^{-3} T]$  between 4 and 300 K. (Author abstract) 8 refs.

### Doping

**094745 DOPING OF LEAD SELENIDE WITH THALLIUM.** A study was made of the properties of thallium-doped lead selenide as a function of the charge composition during crystal growth from vapor according to the vapor-liquid-solid mechanism. It is shown that thallium is an acceptor impurity, and from a charge of composition  $\text{Pb}_x\text{Te}_{1-x}\text{Se}_x$  with  $2 = 0.413$  and  $y \geq 0.018$  and with  $y = 0.01$  and  $x \leq 0.52$  a material with p-type conductivity is obtained. The dependence of the composition of thallium-doped lead selenide during diffusion annealing on the thallium vapor pressure at constant lead vapor pressure is determined. It is shown that at a lead vapor pressure of 1.3332 Pa and a thallium vapor pressure  $\geq 1.87 \cdot 10^{-3}$  Pa it is possible to obtain crystals with p-type conductivity. 14 refs. In Russian.

### Electric Conductivity

**094746 NON-LINEAR TRANSPORT PROPERTIES OF THE  $\text{PbTe-GeTe}$  SYSTEM.** The dependence of the resistivity on temperature for PbTe crystals alloyed with  $< 10\%$  GeTe shows a smooth resistivity hump at low temperatures, which indicates a phase transition. Below the resistivity hump the behavior of the system is non-ohmic. The I-V characteristics at these low temperatures are S shaped. At a critical current density the system oscillates. The resistivity anomaly and the critical temperature at which this anomaly occurs was found to depend on the current density. (Author abstract) 18 refs.

Electric Properties See Also SUPERCONDUCTING MATERIALS—Impurities.

**094747 STRUCTURAL AND ELECTRICAL PROPERTIES OF  $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$  FILMS GROWN BY MOLECULAR BEAM EPITAXY.** Thin epitaxial layers of  $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$  were grown on (100) KCl substrates by molecular beam epitaxy using a single Knudsen source. A typical source temperature of 600°C and substrate temperatures of 250 to 350°C were used. Laue, X-ray, RHEED, SEM, and Van der Pauw techniques employed to characterize these films. Layers 4 to 5  $\mu\text{m}$  thick grown at a growth rate of 0.75  $\mu\text{m}/\text{h}$ . These layers are p-type having carrier concentrations in the range of  $10^{17}$  to  $10^{18} \text{ cm}^{-3}$  and mobilities on the order of  $10^3 \text{ cm}^2/\text{Vs}$  at 110 K. The composition x in the films is found to vary with the substrate temperature. Films grown at 325°C exhibit the same value of x as the source material. (Edited author abstract) 20 refs.

**094748 PHOTOINDUCED ELECTRIC PROPERTIES OF  $Pb_{1-x}Sn_xTe$  SINGLE CRYSTALS.** It was established that the simultaneous action of  $CO_2$ -laser radiation and an external electric field of frequency  $f \leq 10^5$  Hz and strength of the order of that of the laser wave electric field leads to a lowering of the hole concentration or an increase of the electron concentration of the same order as without an electric field but within a shorter time period. The influence of an electric field alone leads to no detectable changes in the electrical characteristics. Changes in the electrical properties upon variation of the orientation of the external electric field with respect to laser wave electric field direction were also established. 5 refs.

## Growth

**094749 PRECIPITATES IN  $PbTe:Cr$  CRYSTAL GROWN BY THE BRIDGMAN METHOD.** X-ray diffraction measurements and electron microprobe analysis were performed on  $PbTe$  crystals grown by the Bridgman method doped with 1.2 wt% Cr. Scanning electron microscopic observations and electron microprobe analysis carried out on the (110) oriented samples revealed needle-like precipitates enriched in chromium and tellurium. It was confirmed that the composition of the widest precipitates was equal to  $Cr_3Te_4$ . It corresponded to mixing of two compounds:  $Cr_2Te_3$  and  $CrTe$ . Using X-ray diffraction measurements, additional phases such as  $CrTe$  monoclinic,  $Cr_2Te_3$  hexagonal and  $CrTe$  hexagonal have been found in the samples. (Edited author abstract) 11 refs.

**094750 ELECTRIC PROPERTIES OF  $PbSe$  FILMS ON A POLYIMIDE SUBSTRATE.** Using methods of mathematical experiment design, global polynomial models are constructed for the carrier mobility and concentration of lead selenide films obtained from the vapor phase by the 'hot wall' method on a polyimide substrate. It is shown that, by measuring the technological factors of the film growth process, it is possible to effectively control the electric parameters of the films. The conditions of growth of film material with maximum carrier mobilities and minimum carrier concentrations are optimized. In Russian. 3 refs.

Frenk, D.M.; Voropai, V.A.; Lopyanko, M.A.; Pavlyuk, M.F.; Prokopi, V.V. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 8 Aug 1987 p 1261-1264.

**094751 VORSTELLUNGEN ZUM SCHICHTWACHSTUM VON BLEIPHthalOCYANINDUENNSCHICHTEN.** [Considerations Regarding Lead Phthalocyanine Thin Film Growth]. The effect of the preparation conditions on the structure and properties of lead phthalocyanine thin films is investigated. By means of electron microscopic examination, the simultaneous appearance of the monocline and tricline crystal modification is demonstrated. For the first time, the absorption peaks are given in the visible and IR regions of the monocline modification. The results are summed up in a three-phase model of lead phthalocyanine thin film growth. (Translated author abstract) 17 refs. In German.

Mrwa, Axel; Reinhardt, Carola; Hamann, Claus. *Wiss Z Tech Univ Karl Marx Stadt* v 29 n 2 1987 p 298-305.

**094752 GROWTH OF  $PbTe$  DOPING SUPERLATTICES BY HOT WALL EPITAXY.** The doping behavior of different species for the growth of  $PbTe$  layers has been investigated. For doping with Te, a model calculation for the status of the Te source as a function of the temperature and time is presented and compared with experimental data. The doping of  $PbTe$  using  $Bi_2Te_3$  and  $Tl_2Te$  sources was studied and typical carrier concentrations and mobilities are given. Finally the differences

between the different dopants with respect to interdiffusion are discussed. These results are important for possible device application of  $PbTe$  nipi structures as IR detectors. (Author abstract) 22 refs.

Clemens, Helmut (Montanuniversitaet Leoben, Leoben, Austria). *J Cryst Growth* v 88 n 2 Apr II 1988 p 236-240.

**094753 INFLUENCE OF ELECTROMAGNETIC RADIATION ON THE FIELD OF HOMOGENEITY OF LEAD TELLURIDE.** A substantial reduction in the dimensions and a change in the configuration of the homogeneity region of a narrow gap telluride lead semiconductor grown in a wide temperature range of 450-830°C with photostimulated epitaxy are detected with the effect of laser radiation ( $\lambda = 0.35$  micron) on the growth zone. (Author abstract) 2 refs.

## Impurities

**094754 IMPURITY LEVELS IN  $PbTe$  AND  $Pb_{1-x}Sn_xTe$ .** The doping characters of vacancies, the existence of impurity resonances, Fermi-level saturation and de-saturation, the sensitivity of the resonances to host chemistry, the behavior of In as both a donor and an acceptor in  $Pb_{1-x}Sn_xTe$ , and the occurrence of other apparently anomalous valences of impurities in IV-VI semiconductors are shown to be simple and direct consequences of a covalent defect theory. Several important defects are assigned to 'incorrect' or 'anti' sites. (Edited author abstract) 23 refs.

Lent, Craig S. (Univ of Notre Dame, Notre Dame, IN, USA); Bowen, Marshall A.; Allgaier, Robert S.; Dow, John D.; Sankey, Otto F.; Ho, Eliza S. *Solid State Commun* v 61 n 2 Jan 1987 p 83-87.

**094755 SPIN SPLITTING IN NARROW-GAP  $Pb_{1-x}Sn_xTe$  SEMICONDUCTORS.** The g factor in the solid solutions  $Pb_{1-x}Sn_xTe$  of the p and n type ( $x = 0, 0.1, 0.19, 0.2, 0.28, \text{ and } 0.38$ ), doped with germanium, cadmium, and bismuth, is determined from investigations of the quantum oscillations of the magnetoresistance. Comparison of the results obtained with theoretical calculations, taking into account the dependence of the matrix element of the momentum operator on the composition x, shows that the experiment agrees well with the theory within the framework of Dimmock's model. Analysis of the experimental results indicate that doping with nonmagnetic impurities does not affect the magnitude of the spin splitting. (Author abstract) 27 refs.

Dmitriyev, A.I. (Acad of Sciences of the Ukrainian SSR, USSR); Lashkarev, G.V. *Sov Phys J* v 30 n 8 Aug 1987 p 711-716.

## Magnetic Properties

**094756 ELECTRON PARAMAGNETIC RESONANCE OF MAGNETIC CLUSTERS IN  $Pb_{1-x}Gd_xTe$ .** Measurements of electron paramagnetic resonance (EPR) and of susceptibility with a superconducting quantum interference device (SQUID) have been performed on  $Pb_{0.995}Gd_{0.005}Te$  crystals from 4.2 to 300 K. The EPR spectra consist of two components, one showing the fine structure of  $Gd^{3+}$  ions in a cubic environment and the other a broad line, which we attribute to clusters of interacting Gd ions. The resonant field of the cluster line appears to be due to an exchange-narrowing mechanism. The ratio of cluster-line intensity to fine-structure intensity increases with decreasing temperature down to 10 K and then decreases. This decrease may be related to the spin freeze-out seen in ac susceptibility. The line-width broadening of the cluster and the single-ion lines are similar below 20 K, with a higher rate for the cluster line. The Curie-Weiss temperature is negative and small for both clustered and single spins, reflecting a weak antiferromagnetic interaction. (Edited author abstract) 15 refs.

**094757 FUNDAMENTAL ABSORPTION EDGE OF  $PbGa_2S_4$ .** Optical absorption spectra of  $PbGa_2S_4$  were measured in the photon energy range from 2.0 to 3.2 eV and for temperatures between 32 and 300 K.  $PbGa_2S_4$  is found to be an indirect-gap semiconductor with a gap energy of 2.84 eV at room temperature. At slightly higher energies the fundamental edge is followed by a direct gap with an energy of 2.91 eV at 300 K. The results obtained are compared with previous measurements and with experimental data for  $CdGa_2S_4$  having similar near-edge optical properties. (Author abstract) 13 refs.

Neumann, H. (Karl-Marx-Univ, Leipzig, East Ger); Hoerig, W.; Nook, G.; Syrbu, N.N. *Solid State Commun* v 65 n 2 Jan 1988 p 155-157.

**094758 OPTICAL BISTABILITY IN  $PbSnTe$  AT 10  $\mu M$ .** Experimental evidence of optical hysteresis is found for the first time in  $Pb_{1-x}Sn_xTe$ . Thus, the possibility of optical bistability in lead chalcogenides by a continuous wave laser excitation is realized. Possible mechanisms of the observed nonlinear refraction in the sample due to the thermal effects or to the free carriers generation, are discussed. (Author abstract) 13 refs.

**094759 NONLINERITIES IN EXCITONIC LUMINESCENCE OF DIRECT-GAP SEMICONDUCTORS UNDER VERY LOW OPTICAL EXCITATION LEVELS.** The dependences of peak luminescence intensity  $I_{lum}$  for free and bound excitons on the level  $I_{exc}$  of the above-gap optical exciton are studied in direct-gap semiconductors  $PbI_2$  and  $CdSe$  within a wide range  $10^{11} \leq I_{exc} \leq 10^{19}$  quanta  $cm^{-2} s^{-1}$ . The experimental dependences  $I_{lum} = f(I_{exc})$  are well represented by a nonlinear power law. The degree of nonlinearity increases gradually with the decrease of  $I_{exc}$  and also becomes higher with increasing of temperature. Linearity is sometimes observed only at sufficiently high  $I_{exc}$  above  $10^{16}$  quanta  $cm^{-2} s^{-1}$ . A phenomenological theoretical model is proposed which accounts for non-radiative surface recombination and non-uniform spatial distribution of the excited carriers and provides satisfactory qualitative agreement with the experimental findings. (Edited author abstract) 17 refs.

## Oxidation

**094760 SPECIAL FEATURES OF THE REACTION BETWEEN TETRAGONAL  $PbO$  AND OXYGEN.** A study was made of the reaction between tetragonal lead monoxide and oxygen at 690-810 K and at  $O_2$  pressures exceeding the dissociation pressure of red lead up to  $1.10^5$  Pa. The existence of supersaturated solid solutions of oxygen in  $\alpha$ - $PbO$  is noted. These solutions form under conditions where the formation of a new condensed phase ( $Pb_3O_4$ ) for kinetic reasons, does not occur. 13 refs. In Russian.

## Photoconductivity

**094761 RESIDUAL PHOTOCONDUCTIVITY IN  $Pb_{0.78}Sn_{0.22}Te$  IN THE FAR INFRARED RANGE OF THE SPECTRUM.** No red boundary for the phenom-

non of residual photoconductivity is found to wavelengths of approximately 350 microns in  $\text{Pb}_{0.78}\text{Sn}_{0.22}\text{Te}:\text{In}$ . The nature of the temperature and time relaxation in the longwave range of the spectrum is found to be the same as in the shorter wave range. An explanation of the phenomenon within a model of Jahn-Teller electron capture centers is proposed. (Author abstract) 11 refs.

**Photovoltaic Effects** See CERAMIC MATERIALS—Thin Films.

### Physical Properties

**094762 FARADAY EFFECT APPROACH TO A STUDY OF  $\text{Al}^{\text{IV}}\text{B}^{\text{VI}}$  NARROW-GAP SEMICONDUCTOR BAND STRUCTURE.** The magnetooptical Faraday effect in the transparency range of  $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$  ( $0.9 \leq x \leq 0.23$ ) and  $\text{PbSe}$  single crystals with carrier concentrations from  $2 \times 10^{16}$  to  $2 \times 10^{18} \text{ cm}^{-3}$  is investigated under applied magnetic fields up to 6 T over the temperature range  $T = 4.2$  to 300 K. g-factors and effective masses of carriers are determined within the range of  $T = 4.2$  to 300 K. It is shown that the experimental results with or without quantization of the energy spectrum may be interpreted only under a particular condition. Some new values of Dimmock six-band model parameters are obtained taking this condition into account. (Edited author abstract) 21 refs.

Martynchuk, E.K. (Acad of Sciences of the Ukrainian SSR, Kiev, USSR); Sizov, F.F. *Phys Status Solidi B* v 145 n 1 Jan 1988 p 309-318.

### Precipitation

**094763 PREPARATION OF BARIUM TITANYL OXALATE TETRAHYDRATE AND ITS UTILIZATION IN HIGH-CURIE-POINT BARIUM-LEAD TITANATE CERAMICS.** Barium titanyl oxalate tetrahydrate (BTOX) was prepared by coprecipitation method in which a mixture of barium-titanium chloride aqueous solution was slowly added to an ethanol solution of oxalic acid at room temperature. Aging after coprecipitation decreased the BET surface area of the precipitated barium titanyl oxalate tetrahydrate and the  $\text{BaTiD}_{20.5}$  second phase content of the calcined powder.  $\text{Ba}_{1-x}\text{Pb}_x\text{TiO}_3$  ceramics in which  $x = 0.50$  was synthesized by the reaction of BTOX,  $\text{PbO}$ ,  $\text{TiO}_2$  and dopants. A  $\text{Ba}_{0.5}\text{Pb}_{0.5}\text{TiO}_3$  ceramic with PTCR (positive temperature coefficient of resistivity) characteristics of 3.7 orders of magnitude, a minimum resistivity around 100 ohm/cm and a Curie point at 320°C was obtained. Factors such as the  $\text{Sb}_2\text{O}_3$ , MnO dopants contents, the Ti/(Ba+Pb) ratio, sintering temperature and microstructures which influence the PTCR characteristics were studied. (Author abstract) 7 refs.

Kao, Chih-Chun (Industrial Technology Research Inst, Hsinchu, Taiwan); Yang, Chun-Lien. *MRL Bull Res Dev* v 1 n 2 Sep 1987 p 57-62.

### Radiation Effects

**094764 CONTROL OF CARRIER LIFETIME IN  $\text{PbTe}$   $n\text{-ipi}$ -SUPERLATTICES BY EXTERNAL PHOTOINJECTION.** Photoexcitation of  $\text{PbTe}$  doping superlattices at different intensity levels can have a large influence on nonequilibrium carrier lifetime which in turn is determined both by  $\text{PbTe}$  bulk properties and details of the superlattice periodic potential. Such 'tunability' in the recombination rate is examined theoretically in a model which considers details of carrier tunneling and thermal excitation in the superlattice as well as the role of Auger recombination as a decay channel at high densities. Good agreement is obtained with experimental studies of transient photoconductivity in which picosecond pulses from a Nd:YAG laser have been used to vary the effective lifetime from less than 2 nsec up to 10 usec. We also show how the presence of 300 K background radiation has an important influence on practical recombination rates. (Author abstract) 11 refs.

Oswald, J. (Montanuniv Leoben, Leoben, Austria); Bauer, G.; Goltso, W.C.; Nurmikko, A.V. *Superlattices Microstruct* v 4 n 2 1988, Pap from the Chicago Conf, Chicago, IL, USA p 159-163.

### Spectroscopic Analysis

**094765 AUGER ELECTRON SPECTROSCOPY OF LASER-DEPOSITED  $\text{Pb}_{1-x}\text{Cd}_x\text{Se}$  FILMS.** Auger electron spectroscopy (AES) was applied for the film constitution investigation. Two groups of samples were prepared, one from a monolithic polycrystalline material and the other from tablets. The AES investigations show a lack of oxygen in both cases, despite the inevitable oxidation during the course of tablet preparation. The latter fact still remains open to discussion. Another important result from AES investigations is that there are no constitutional differences in the layers from pulse to pulse and there are no intermediate transitional layers, formed in the time (approx. 6 sec) between the pulses. 6 refs.

Sendova, M.S. (Sofia Univ, Sofia, Bulg); Maksimov, M.H.; Gaskov, A.M. *J Mater Sci Lett* v 7 n 2 Feb 1988 p 93-94.

**094766 DIRECT OBSERVATION OF GIANT DEVIATIONS FROM STOICHIOMETRY IN SINGLE CRYSTALLINE  $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$  BY MEANS OF THE MOSSBAUER EFFECT ON THE  $^{119}\text{Sn}$  NUCLEI.** The spectra of ordinary  $\text{Pb}_{0.77}\text{Sn}_{0.23}\text{Te}$  and metallic bare shown. The spectrum of the studied hyperstoichiometric samples consists of two lines which indicates the presence of two non-equivalent states of tin. Computer assisted determinations of the linewidth, isomer shift  $\delta$ , and magnitude of the effect were carried out as well as decomposition of the complex spectra into singlets. Not only tin but also lead occupies interstitial sites of the materials under investigation. The total concentration of interstitial metal atoms reaches values on the order of one atom per elementary cell. 2 Refs.

Baltrunas, D. (Acad of Sciences of the Lithuanian SSR, Vilnius, USSR); Zayachuk, D.M.; Motiejunas, S.; Starik, P.M. *Phys Status Solidi A* v 106 n 2 Apr 1988 p K173-K175.

**094767 ELECTRON SPIN RESONANCE STUDIES ON THE SUPERLATTICES  $\text{PbTe-Pb}_{1-x}\text{Eu}_x\text{Te}$  PREPARED BY HOT WALL EPITAXY.** Electron spin resonance spectra of the superlattices  $\text{PbTe-Pb}_{1-x}\text{Eu}_x\text{Te}$  prepared by a hot wall epitaxy technique have been examined, in which  $x$  denotes the fraction of europium or periodic monolayers of  $\text{Pb}_{1-x}\text{Eu}_x\text{Te}$  calculated by assuming no diffusion of europium(II) into the  $\text{PbTe}$  layer. For the spectra of the superlattices the linewidth was found to vary markedly over the range of  $x$  between 0.1 and 1, proving that most of the europium(II) exists on the monolayer of  $\text{Pb}_{1-x}\text{Eu}_x\text{Te}$ . In the case of randomly europium-doped crystalline  $\text{Pb}_{1-y}\text{Eu}_y\text{Te}$  of  $y = 0.003$ , in which  $y$  is the fraction of europium doped in the crystalline  $\text{PbTe}$ , the overall splitting of the ground state parameter of europium(II) in a cubic field surrounded by telluride ions as estimated to be  $1570 \times 10^{-4}$ . (Edited author abstract) 7 Refs.

Nakamura, Takato (Shizuoka Univ, Hamamatsu, Jpn); Ishida, Akihito; Fujiyasu, Hiroshi. *Thin Solid Films* v 161 Jul 1988 p 149-156.

**094768 DEPTH PROFILE OF THE ELEMENTS IN LEAD CHALCOGENIDE LAYERS.** The results of the quantitative X-ray electron spectroscopy and Auger electron spectroscopy of lead chalcogenide layers obtained by the hot wall technique are presented in this paper. The initial compounds  $\text{PbTe}$ ,  $\text{PbS}$ ,  $\text{PbSe}$ ,  $\text{PbS}_{1-x}\text{Se}_x$ ,  $\text{PbSe}_{1-x}\text{Te}_x$  and  $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$  were brought to  $P_{\text{min}}$  by the method of continuous and multiple sublimation-crystallization at the evaporation temperature. The layers were grown by congruent sublimation. The composition of the resulting layers was identical to that of the initial material. After sensitizing, polycrystalline films of  $\text{PbS}$  and  $\text{PbS}_x\text{Se}_{1-x}$  on photoglass supports displayed a non-homogeneous distribution of the elements across the near-surface

layer. The films that contained a larger amount of lead in the near-surface layer and had a better developed relief of the elemental distribution across the layer exhibited greater photosensitivity. (Edited author abstract) 9 Refs.

Kovalev, A.N. (Helsinki Univ of Technology, Helsinki, Finl); Korabiev, V.V. *Thin Solid Films* v 161 Jul 1988 p 281-287.

### Structure

**094769 ELECTRONIC STRUCTURE AND SYMMETRY PROPERTIES OF THE ENVELOPE FUNCTIONS IN  $\text{PbTe-Pb}_{1-x}\text{Sn}_x\text{Te}$  SUPERLATTICES.** In the framework of J.O. Dimmock's two band model and in the constant band edge approximation within each layer, the electronic structure for the  $\text{PbTe-Pb}_{1-x}\text{Sn}_x\text{Te}$  SL is studied. The study is carried out for the  $\langle 111 \rangle$  valley,  $k_1 = 0$ , and taking into account all the possible solutions for the effective Hamiltonian. A new dispersion relation and new zero energy gap conditions are derived. Numerical calculations reveal that the inclusion of the largest wave vector solutions do not substantially modify the energy spectrum obtained when such solutions are excluded. (Author abstract) 8 refs.

Gondar, J. Lopez (Univ of Havana, Havana, Cuba); de Dios Leyva, M. *Phys Status Solidi B* v 142 n 2 Aug 1987 p 445-453.

### Synthesis

**094770 SOLIDUS SURFACE OF THE SOLID SOLUTION  $\text{Pb}_{1-x}\text{S}_x\text{Se}_{1-x}$  ( $0.4 \leq x \leq 0.8$ ).** A study was made of the boundaries of the range of existence of the solid solution of lead sulfide and lead selenide, using the 'frozen-equilibrium' and 'first-crystal' methods. It was found that the maximum solubility of lead in the solid solution with  $x = 0.05$  is attained at 1140-1150 K and is equal to  $1.9 \cdot 10^{19} \text{ cm}^{-3}$ . The solidus surface of the  $\text{PbSe-PbS}$  system in the lead-rich region is displaced toward the lead side. In Russian. 7 refs.

Kuznetsova, L.A.; Shtanov, V.I.; Zlomanov, V.P. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 4 Apr 1987 p 537-539.

### Thermodynamic Properties

**094771 PARTIAL PRESSURES AND THERMODYNAMIC PROPERTIES FOR LEAD TELLURIDE.** The optical absorbance of the vapor over pure Te, over  $\text{Pb-Te}$  samples containing 49.01, 49.70, 51.26, and 55 atom percent (a/o) Te, and over a 1.56 mg crystal of  $\text{PbTe}$  is measured between 230 and 700 nm for optical cell temperatures of 1028, 1133, 1273, and 1353 K, and for a range of sample temperatures. The partial pressures of  $\text{Te}_2$ ,  $\text{P}_2$ , and of  $\text{PbTe}$  are extracted from the data. For  $\text{Te-saturated PbTe(c)}$ ,  $P_2$  reaches a maximum value of  $1.5$  to  $1.7 \times 10^{-2} \text{ atm}$  between 1064 and 1099 K and drops to  $2.6 \times 10^{-3} \text{ atm}$  at the 1197 K maximum melting point. (Edited author abstract) 32 refs.

Huang, Yu (Marquette Univ, Milwaukee, WI, USA); Brebrick, R.F. *J Electrochem Soc* v 135 n 2 Feb 1988 p 486-496.

**094772 PARTIAL PRESSURES AND THERMODYNAMIC PROPERTIES OF  $\text{PbTe-SnTe}$  SOLID AND LIQUID SOLUTIONS WITH 13, 20, AND 100 MOLE PERCENT  $\text{SnTe}$ .** The partial pressures of  $\text{Te}_2$ ,  $\text{PbTe}$ , and  $\text{SnTe}$  are determined for the solid solutions ( $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$ ) with  $x = 0.13, 0$ , and 1.0 and for  $y$  values corresponding to  $\text{Pb-Sn}$  saturation, to  $\text{Te}$  saturation, and to compositions within the homogeneity range, as well as for the liquids forming from these solids. The partial pressures are extracted from measurements of optical absorbance of the coexisting vapor phase between 230 and 700 nm. A number of thermodynamic and phase

program data are obtained. The enthalpy of fusion of congruently melting, 50.4 a/o Te SnTe, is  $45.7 \pm 1.2$  kJ/mol. (Edited author abstract) 45 refs.

Huang, Yu (Marquette Univ, Milwaukee, WI, USA); Brebrick, R.F. *J Electrochem Soc* v 135 n 6 Jun 1988 p 1547-1559.

## Thin films

**094773 EFFECT OF HYDROGEN ON THE ELECTRICAL PROPERTIES OF p-TYPE  $\text{Pb}_{0.8}\text{Sn}_{0.2}\text{Te}$  THIN FILMS.** D.C. conductivity and Hall Coefficient studies were made in the temperature range 77-300 K on p-type  $\text{Pb}_{0.8}\text{Sn}_{0.2}\text{Te}$  thin films exposed to molecular hydrogen gas at high pressures (150-500 PSI) for 2 h. The Hall Coefficient is found to increase with the increase in hydrogen pressure and reaches a maximum at about 250 PSI. With further increase in the gas pressure, the Hall Coefficient is found to decrease and to change its sign. Mobility however increases with the increase in the gas pressure. Hydrogen is found to stabilize the electrical properties of these films. (Author abstract) 8 refs.

Dawar, A.L. (Univ of Delhi, Delhi, India); Jagadish, C.; Shishodia, P.K.; Sharma, Sanjay; Kapoor, S.K.; Sachar, B.K.; Mathur, P.C. *J Phys Chem Solids* v 49 n 1 1988 p 113-114.

**094774 OXYGEN DIFFUSION TO THE BULK AND CRYSTALLITE BOUNDARIES IN PbTe FILMS.** Thermal oxygen diffusion to the bulk and at crystallite boundaries (CB) in PbTe films have been experimentally investigated. Ions  $\text{O}^{+}$  implanted in sub-surface layer of films served as source of diffusion to the bulk; this diffusion process was provided by annealing in vacuum. Diffusion along CB was stimulated by air annealing of the films. It was proved that changes of properties during diffusion in n-type PbTe films mainly occurred owing to localization of oxygen at CB. For investigated films oxygen diffusion constant and activation energy of the process have been obtained. (Author abstract) 8 refs.

Atakulov, Sh.B. (State Pedagogical Inst, Fergana, USSR); Kokanbaev, I.M. *Solid State Commun* v 61 n 6 Feb 1987 p 369-372.

**094775 BAND-GAP VARIATION IN TERNARY ALLOY FILMS.** Measurements of the optical absorption of thin films of  $\text{Pb}_{1-x}\text{Hg}_x\text{S}$  show a sharp increase in the optical band gap with a small addition of mercury to PbS. It is suggested that the band gap is increased in the films as a result of the formation of new conduction and valence bands. (Author abstract). 13 Refs.

Jain, Mukesh (Indian Inst of Technology, New Delhi, India). *Philos Mag Lett* v 58 n 1 Jul 1988 p 59-62.

**094776 INFLUENCE OF THE FILM HISTORY ON SOME ELECTROPHYSICAL PROPERTIES OF VE, CAD, AND COD PbSe FILMS.** The influence of the 'biography' of the PbSe films prepared by vacuum evaporation (VE) and chemical deposition selenosulfate based procedure - CAD - and selenourea based procedure - COD) on their structure, phase composition, resistivity, and photoconductivity is studied. The considered processes perturbing the film-air system are aging effects and different kinds of thermal treatments. It is evidenced that the number and the types of the active adsorption sites are the factors which differentiate between an 'as-grown' film and a film with a certain history. (Author abstract). 12 Refs.

Candea, Rodica M. (Inst of Isotopic & Molecular Technology, Cluj-Napoca, Rom); Biro, L.P.; Dadarlat, N.; Borodi, G.; Darabont, A.; Fitori, P.; Turcu, Rodica. *Phys Status Solidi A* v 108 n 1 Jul 1988 p 233-240.

**094777 PROPERTIES OF VARIABLE BAND GAP II-VI-IV TERNARY ALLOY THIN FILMS.** Thin films of  $(\text{PbCH})_{1-x}(\text{HgCH})_x$  ( $\text{CH} = \text{S, Se and Te}$ ;  $0.07 \leq x \leq 0.93$ ) materials were deposited at different temperatures by flash evaporation. Structural and optical analyses indicate that under appropriate conditions of growth, the

films grow as single phase and the characteristics are sensitive to mercury concentration ( $x$ ) and substrate temperature. The direct optical band gap can be varied between 1.43-2.17 eV in  $\text{Pb}_{1-x}\text{Hg}_x\text{S}$ , 0.20-0.06 eV in  $\text{Pb}_{1-x}\text{Hg}_x\text{Se}$  and 0.27-0.09 eV in  $\text{Pb}_{1-x}\text{Hg}_x\text{Te}$  films by changing mercury concentration from 0.07 to 0.93. The observed characteristics of the films can be explained by considering that the new lattices form by atom-by-atom condensation of evaporated materials. (Author abstract) 13 refs.

## SEMICONDUCTING LIQUIDS

### Physical Properties

**094778 SEMICONDUCTIVITY IN THE LIQUID Cu-TlTe SYSTEM.** Measurements of the electrical conductivity, the magnetic susceptibility, and the thermoelectric power for the liquid Cu-TlTe system are made in wide temperature and composition ranges. It is observed that the conductivity for the system falls abruptly at the composition of 50 mol percent Cu and the thermoelectric power changes its sign around this composition. The diamagnetic susceptibility also shows a sharp maximum at the corresponding composition. The experimental results of the present work are compared with the previous data of liquid telluride systems and are discussed in the light of current transport theories employed in amorphous and liquid semiconductors. (Author abstract). 19 Refs.

Satow, T. (Yamagata Univ, Yamagata, Jpn); Ishikawa, H.; Uemura, O. *Phys Status Solidi B* v 146 n 2 Apr 1988 p 661-669.

### Thermodynamic Properties

**094779 THERMAL EXPANSION AND STRENGTH CHARACTERISTICS OF THE INTER-ATOMIC BOND IN MELTS OF THE COMPOUNDS  $\text{Bi}_2\text{Se}_3$ ,  $\text{Sb}_2\text{Se}_3$  AND  $\text{Bi}_2\text{Te}_3$ .** A study was made of the temperature dependence of the specific volumes of bismuth and antimony chalcogenides in the liquid phase. The thermal expansion coefficients of melts of  $\text{A}_2\text{V}_3\text{VI}$  compounds were calculated at various temperatures. On the basis of these results, the characteristic Debye temperatures in the liquid phase at the melting point of each compound were estimated. It is noted that the melting process leads to a sharp increase in the thermal expansion coefficients (2.5-fold) and a decrease in the Debye temperature (1.6-fold), which attests to significant changes in the vibrational spectrum of atoms of  $\text{A}_2\text{V}_3\text{VI}$  compounds during the crystal-melt phase transition. In Russian. 11 refs.

Thermodynamics See SEMICONDUCTING SILICON—Growth.

## SEMICONDUCTING MANGANESE COMPOUNDS

### Electric Conductivity

**094780 HIGH-TEMPERATURE ELECTRICAL TRANSPORT PROPERTIES OF MANGANESE TELLURIDE.** Electrical conductivity, thermoelectric power and dielectric constant of polycrystalline manganese telluride ( $\text{MnTe}$ ) have been measured in the temperature range 300-100 K, using pressed pellets of powdered samples.  $\text{MnTe}$  shows semiconducting behavior in the entire temperature range studied. It exhibits extrinsic conduction up to 600 K but is intrinsic in nature above 600 K. Low mobility of the charge carriers ( $\mu \approx 10^{-2}$

$-10^{-3} \text{ cm}^2 \text{ V}^{-1} \text{ s}^{1/2}$ ) and low value of the mean free path (0.039 Å) in the intrinsic region (600-1000 K) indicate localization of the charge carriers, due to strong electron-phonon interaction. (Author abstract) 25 refs.

Yadava, Y.P. (Indian Inst of Technology, Kanpur, India). *Mater Lett* v 6 n 8-9 May 1988 p 297-302.

**094781 RESISTIVITY CHANGE OF  $\gamma\text{-MnO}_2$  IN A  $\text{H}_2/\text{Ar}$  MIXED GAS ATMOSPHERE.** In the present letter a change in resistivity of unexpected direction in  $\gamma\text{-MnO}_2$  with N-type semiconduction behaviour in the  $\text{H}_2/\text{Ar}$  mixed gas atmosphere is reported. The anomalous behaviour of the  $\text{H}_2$ -gas sensing of  $\gamma\text{-MnO}_2$  was found to be due to  $\gamma\text{-MnO}_2$  behaving in reverse to a normal N-type semiconductor, showing a resistivity increase in the reducing mixed gas  $\text{H}_2/\text{Ar}$ , contrary to its polymorph  $\gamma\text{-MnO}_2$ . As for the practical application, the reactive behaviour of excellent gas sensing is to be expected for a gas sensor. 4 refs.

Li, Jian-Bao (Univ of Tokyo, Jpn); Koumoto, Kunihito; Yanagida, Hiroaki. *J Mater Sci Lett* v 7 n 4 Apr 1988 p 331-334.

### Magnetic Properties

**094782 NEAREST NEIGHBOR EXCHANGE CONSTANTS IN  $\text{Hg}_{1-x}\text{Mn}_x\text{Te}$ ,  $\text{Hg}_{1-x}\text{Mn}_x\text{Se}$  AND OTHER SEMIMAGNETIC SEMICONDUCTORS.** High field magnetization experiments ( $B \leq 35$  T) have been performed at 1.8 K in  $\text{Hg}_{1-x}\text{Mn}_x\text{Te}$  ( $x=0.056$ ) and  $\text{Hg}_{1-x}\text{Mn}_x\text{Se}$  ( $x=0.0650$ ). At  $B > 6$  T the magnetization exhibits step-like increases due to the magnetic field alignment of the antiferromagnetically coupled nearest neighbor Mn pairs and triangles. A theoretical fit of the magnetization curves provide a determination of NN exchange constants  $J_{\text{NN}}/k_B = (-5.1 \pm 0.5)$  K for  $\text{Hg}_{1-x}\text{Mn}_x\text{Te}$  and  $J_{\text{NN}}/k_B = (-6 \pm 0.5)$  K for  $\text{Hg}_{1-x}\text{Mn}_x\text{Se}$ . Analysis of all the presently available  $J_{\text{NN}}$  values for semimagnetic semiconductors is presented and the observed trends and discrepancies are discussed. (Author abstract) 27 refs.

### Thin Films

**094783 SOLUTION GROWTH TECHNIQUE FOR THE DEPOSITION OF MANGANESE SULPHIDE THIN FILM.** Thin films of  $\text{MnS}$  were deposited by the solution growth technique using manganese acetate, triethanolamine, hydrazine, thioacetamide and ammonium chloride. Using x-ray diffraction, the film was shown to be amorphous. The optical band gap was found to be  $5.2 \times 10^{-19}$  J (3.25 eV). The activation energy of electrical conduction was observed to be  $2.4 \times 10^{-19}$  J (1.5 eV). The films were found to be p type using the thermoelectric probe method. The room temperature conductivity was found to be  $1.26 \times 10^{-5} \text{ S cm}^{-1}$ . The bath parameters were studied to optimize the film thickness. The terminal thickness of 260 nm is reached after  $2.88 \times 10^4$  s. (Author abstract) 13 refs.

## SEMICONDUCTING ORGANIC COMPOUNDS See Also PHOTOCONDUCTING MATERIALS; TRANSISTORS, FIELD EFFECT—Thin Films.

**094784 APPLICATION OF PHOSPHINE TELLURIDES TO THE PREPARATION OF GROUP II-VI (2-16) SEMICONDUCTOR MATERIALS.** In order to find low-temperature routes to metal tellurides, we have investigated some of the reactions of phosphine tellurides. Via the phosphine telluride, tellurium is chemically transported by  $\text{PM}_3$  under very mild conditions. Triethylphosphine telluride reacts with Hg at room temperature and with  $\text{HgR}_2$  ( $\text{R} = \text{Et, Ph}$ ) at  $115^\circ\text{C}$ , in each case giving

HgTe as the sole solid-state product. We studied the reaction with  $\text{HgPh}_2$  in greater detail, showing that  $\text{Ph}_2\text{Te}$  and  $\text{Ph}_2\text{Te}_2$  are the major organic products. (Edited author abstract) 12 refs.

## Charge Carriers

**094785 CARRIER DRIFT MOBILITIES IN SOME ORGANIC SOLIDS. A SEARCH FOR ORGANIC PHOTOVOLTAIC MATERIALS. II. CHARGE TRANSPORT CALCULATIONS IN s-TETRAZINE AND 4-PHENYLAZOAZOBENZENE.** Excess electron and excess hole mobilities of S-tetrazine and 4-phenylazoazobenzene are calculated using the tight binding approximation with SCF-AOs as a basis set. The applicability of the band model in these organic solids is discussed in the light of Munn and Siebrand's theory of charge transport in organic solids. The results show that these two organic solids may be good candidate materials for organic photovoltaic devices. (Author abstract) 19 refs.

Kumar, B. (Devi Ahilya Univ, Indore, India). *Phys Status Solidi B* v 143 n 2 Oct 1987 p 663-673.

## Electric Conductivity

**094786 TETRAKIS(METHYLTELURIO)TETRAETHIAFULVALENE ( $\text{TTeC}_4\text{-TTF}$ ), A HIGH-MOBILITY ORGANIC SEMICONDUCTOR.** The authors have found a class of highly conductive single-component organic semiconductors - the tetrakis(alkylthio)tetrathiafulvalenes - and have given these systems on the descriptive title of 'molecular fastener'. In a program to synthesize single-component molecular assemblies with high conductivity, they then discovered a new organic semiconductor, tetrakis(alkyltelluro)tetrathiafulvalene with an electric resistivity of  $8.1 \times 10^4$  ohm-cm and a high charge mobility,  $20\text{-}30 \text{ cm}^2 \text{V}^{-1} \text{s}^{-1}$ . This unusually low resistivity is explained in terms of the molecular packing and the manner of stacking within the crystal. (Edited author abstract) 11 refs.

Inokuchi, H. (Inst for Molecular Science, Okazaki, Jpn); Imaeda, K.; Enoki, T.; Mori, T.; Maruyama, Y.; Saito, G.; Okada, N.; Yamochi, H.; Seki, K.; Higuchi, Y.; Yasuoka, N. *Nature* v 329 n 6134 Sep 3-9 1987 p 39-40.

## Electric Properties

**094787 LOW DIMENSIONAL MOLECULAR SEMICONDUCTOR: THE RADICALAR BIS-PHTHALOCYANINATO LUTETIUM  $\text{Pc}_2\text{Lu:CHD 2Cl}_2$ .** Crystals of solvate bisphthalocyaninato-lutetium,  $\text{Pc}_2\text{Lu:CH}_2\text{Cl}_2$ , are shown to be intrinsic molecular semiconductors ( $\sigma_{R,T} = 6 \times 10^{-5} \Omega^{-1}$ ,  $E(\text{act.}) = 0.32 \text{ eV}$ ). Both crystallographic determinations and magnetic properties demonstrate the one-dimensional character of this radicalar material. While dioxygen has drastic and reversible effects on the magnetic properties, it has not any one on transport properties. This is characteristic of spin coupling between the adsorbed oxygen and the radicalar host molecule,  $\text{Pc}_2\text{Lu:CH}_2\text{Cl}_2$ . (Author abstract) 28 refs.

Petit, P. (Inst Charles Sadron, Strasbourg, Fr); Holczner, K.; Andre, J.-J. *J Phys (Paris)* v 48 n 8 Aug 1987 p 1363-1367.

**094788 BARRIER HEIGHTS AND INTERFACE STATES OF METAL/2, 4, 7-TRINITRO-9-FLUORENONE THIN FILM CONTACTS.** The purpose of this note is to present experimental results of determining the barrier height of contacts formed between Al, Cr, Ni, Cu, Ag, and Au and vacuum evaporated 2, 4, 7-trinitro-9-fluorenone (TnF) thin films. Plotting the measured barrier height against the metal electronegativity shows excellent correlation. The barrier height proportionally changes with the metal electronegativity, and the best-fit straight line to the plot has a slope of 0.75 which is numerically in good agreement with the value of  $E_g$

/3.5 = 0.76. This suggests that the contacts also related to the class of metal nonmetal contacts in which the interface states of MOIS type play a dominant role in Schottky barrier formation at metal-nonmetal interfaces. 5 refs.

**094789 LUMINESCENCE AND RELAXATION OF ENERGY IN DISORDERED ORGANIC AND INORGANIC MATERIALS.** We consider the properties of excitons at and below the mobility edge where the stochastic Master equation approach is valid. An analogous formulation can be given before  $\epsilon_c$ . Takagahara has considered the relaxation of band excitons in quantum wells. For excitons diffusing in localized states, we can define an effective pair localized state. This description applies to a large category of problems and has in each case to be analyzed individually. Let us consider the case where the models are appropriate; this would, for example, apply to excitons in QWs and organic materials. 32 refs.

Movaghar, B. (GEC Research Lab, Wembley, Engl); Gruenewald, M.; Ries, B. *Disord Semicond Publ* by Plenum Press, New York, NY, USA and London, Engl, 1987 p 723-743.

**094790 PHYSICAL, THERMAL AND OPTICAL CHARACTERIZATION OF RHODIUM(III) ACETYLACETONATE.** Rhodium(III) acetylacetonate was investigated for its physical, thermal and optical properties. Ultraviolet-visible absorption spectra show absorptions at 320 nm, 260 nm, and 210 nm. Density measurements yielded a value of  $1.75 \text{ g/cm}^3$ . Thermal characteristics were evaluated using differential thermal analysis (DTA). It was found that the compound is not volatile, decomposing upon heating. If heating rates are rapid enough, e.g.  $> 2^\circ\text{C/min}$ , melting at  $267^\circ\text{C}$  can be observed. If heating rates are slower, decomposition is complete before the melting point. If the compound is annealed at  $267^\circ\text{C}$  for four hours decomposition is complete, yielding 99% pure rhodium metal. In an oxidizing atmosphere, on the other hand, the compound decomposes into a product containing 75% rhodium metal which appears to be  $\text{RhO}_2$ . (Author abstract) 13 refs.

**094795 ELECTRICAL PROPERTIES OF MOS AND MIS DIODES USING AN ELECTROCHEMICALLY PREPARED POLY(N-METHYLPYRROLE).** Organic semiconductor devices using electrochemically prepared poly(N-methylpyrrole) (PNP) were characterized by capacitance-voltage (C-V) measurements. A device with aluminum evaporated on the PNP behaved as a MOS (metal-oxide semiconductor) diode in vacuum. Assuming the oxide layer between the metal and the PNP to be pure  $\text{Al}_2\text{O}_3$ , the MOS parameters were calculated. The values obtained for depletion width  $W = 166 \text{ angstrom}$  and acceptor density  $N_A = 10^{18} \text{ cm}^{-3}$  in the PNP were reasonable by comparison with the previously reported values obtained by Schottky analysis. An indium/poly(p-phenylene)-1,3,4-oxadiazole (POD)/PNP diode was prepared, and C-V measurements were carried out in air. The diode behaved like an MIS (Metal-insulator semiconductor) device, but the characteristics showed large variation with frequency. We have proposed a schematic model for this mechanism on the basis of the results obtained by dielectric measurements of POD and the temperature dependence of the MIS characteristics. (Author abstract) 20 refs.

**Charge Carriers**

**094798 THERMALLY STIMULATED SURFACE POTENTIAL DECAY IN HDPE AND THE CROSS-OVER PHENOMENON.** The field strength dependence of thermally stimulated charge decay (TSCD) from corona charged high-density polyethylene (HDPE) was studied in the high temperature region above room temperature up to the melting point. The studies reveal the existence of a deep surface trap as well as a shallow and a deep bulk trap. Charge release from the deep bulk trap is enhanced by high electric fields and gives rise to a cross-over in surface potential decay curves. (Author abstract)

von Berlepsch, H. (Akad der Wissenschaften der DDR, Teltow-Seehof, East Ger); Pinnow, M. *Phys Status Solidi A* v 105 n 2 Feb 1988 p 485-492.

**094799 HOLE TRANSPORT IN CORONA-CHARGED  $12 \mu m$  SHELDAHL FEP SAMPLES INTERPRETED THROUGH A FIELD-DEPENDENT SCHUBWEG MODEL.** Potential build up and decay curves for positive corona charged Sheldahl FEP foils were measured and interpreted using the conventional field-dependent schubweg and a trap structure with shallow traps at the polymer surface (mean life time of  $10^3$  s) and quasi-deep traps (mean detrapping time of  $7 \times 10^3$  s) in the bulk. For this trap, only the product of the mobility by the trapping time is relevant (of the order of  $10^{-10} cm^2/V$ ). Comparison between measurements in pure  $N_2$ , dry air, and ambient air demonstrates that moisture has a not negligible effect on charge transport, decreasing the surface potential. Holes trapped at the surface are located a little beneath the polymer surface. (Edited author abstract) 18 refs.

**Doping** See Also BAND STRUCTURE—Calculations; POLYACETYLENES—Doping.

**094800 ION IMPLANTATION DOPING AND ELECTRICAL PROPERTIES OF HIGH-TEMPERATURE LADDER POLYMERS.** We report the first ion implantation doping studies on high-temperature ladder polymers and show that insulating films of the benzimidazobenzophenanthroline type ladder polymer (BBL) can be doped by boron, argon, and krypton implantation to conductivities as high as  $224 S/cm$  at a dose of  $4.0 \times 10^{16}/cm^2$  while retaining the excellent mechanical properties of the pristine films. Effects of dose (ions/ $cm^2$ ) and beam current density (microamps/ $cm^2$ ) on electrical conductivity at fixed ion energies are reported. The temperature dependence of the conductivity indicates that the implanted ladder polymer films are semiconductors. Spatially selective implantation, creating regions of conducting lines in an insulating matrix, which suggests microelectronic device applications of the ladder polymers, is demonstrated. (Author abstract) 14 refs.

**094801 DIFFUSION PROCESSES IN THE DOPING OF POLYMER FILMS.** A critical review is presented of the various diffusion models and the associated experimental techniques that have been put forth to describe the mass transfer limitations on the overall processes by which polymer films are doped to develop enhanced electrical conductivity. The discussion emphasizes comparative features and their connections with data interpretation. The strengths and weaknesses associated with particular approaches are stressed in order to explain the wide range of diffusion coefficients reported by the many prior investigators, and to suggest further steps that may eventually resolve some contradictions and provide a more satisfactory understanding of the doping and undoping processes for conductive polymers. (Author abstract). 19 Refs.

Perlmutter, Daniel D. (Univ di Roma 'La Sapienza', Rome, Italy); Scrosati, Bruno. *Solid State Ionics* v 27 n 3 Jul 1988 p 115-123.

**Electric Conductivity**

**094802 FREQUENCY-DEPENDENT CONDUCTIVITY IN POLYANILINE.** Frequency(f) and temperature(T) dependence of electrical conductivity  $\sigma(f, T)$  and optical spectrum in polyaniline are presented. The behavior of  $\sigma(f, T)$  at low protonation levels is the same as the lightly doped polypyrrole. These results can be described by the slightly modified Kivelson model, that is, the interpolation hopping between the polaron and bipolaron. The behavior of  $\sigma(f, T)$  in highly protonated polyaniline is the same as in disordered semiconductors. (Author abstract) 19 refs.

Hayashi, Takafumi (Univ of Tokyo, Tokyo, Jpn); Hirai, Yoshinori; Tanaka, Hajime; Nishi, Toshio. *Jpn J Appl Phys Part 2* v 26 n 11 Nov 1987 p 1800-1802.

**Electric Properties**

**094803 PHOTO-ELECTRICAL CHARACTERISTICS OF SEMICONDUCTING POLYMER P3MT/ELECTROLYTE INTERFACE AND CATALYSIS OF Pt ATOMS ON P3MT SURFACE.** The transient and static photoelectrical characteristics of one-dimensional semiconducting polymer poly(3-methyl thiophene)-P3MT/electrolyte and GaAs/electrolyte interfaces are reported. The differences between them have been observed; they result from the differences of energy band structure, elementary excitation state and the property of dopant. The catalysis of Pt atoms, which are plated on the P3MT surface by a photoelectrochemical method, has been observed and the optimum density of Pt atom has been found. The result of surface Auger spectrum analysis of Pt plated P3MT sample is reported. (Author abstract) 10 refs. In Chinese.

**094804 STUDIES OF SEMICONDUCTING ORGANIC POLYMER-GRAPHITE COMPOSITES FROM D.C. TO MICROWAVE FREQUENCIES.** The samples are mixtures consisting of particles of graphite dispersed within a matrix of a doped substituted polyacetylene. The electrical impedance spectra are discussed in terms of inhomogeneity and intrinsic contributions. The frequency dependence of the a.c. conductivity and permittivity has been measured at frequencies between 10 kHz and 12 GHz. The ac conductivity is given by the power-law relation  $\sigma(\omega) \propto \omega^n$  with  $0 < n < 0.4$  at frequencies below 30 MHz,  $0.5 < n < 1$  at frequencies between 30 MHz and 2 GHz and  $1 < n < 2$  at frequencies between 2 GHz and 8 GHz. A saturation occurs at approximately 8 GHz. Various theoretical approaches are presented in order to support such behavior. (Author abstract) 29 refs.

**Electrodeposition**

**094805 APPLICATION OF SUPERCONDUCTING CERAMICS AS SUBSTRATES FOR THE ELECTROCHEMICAL DEPOSITION OF CONDUCTING POLYMERS AND METALS.** Superconducting ceramics of  $Y_1Ba_2Cu_3O_{8-\delta}$  are studied as electrode substrates for electrochemical deposition of conducting polymers (polythiophene, polypyrrole) and metals (Cu, Ag). The superconductivity of the ceramics is found to be insensitive to the electrochemical processes, and even to exposure to iodine vapor and  $\gamma$ -ray irradiation up to 100 Mrad. (Author abstract) 13 refs.

**Electronic Properties**

**094806 ON THE ELECTRONIC STRUCTURE OF POLYTHIENEO [3,4-C] THIOPHENE: A POLYMER WITH VERY SMALL BAND GAP.** Results of ab initio band structure calculations aimed at designing an intrinsic electrically conducting polymer are presented. The electronic structure and conduction properties of a polythiophene derivative, polythieno [3, 4-C] thiophene (PTTP) obtained by fusing another thiophene ring on the  $\beta$ - $\beta'$  bond of each backbone thiophene ring of polythiophene are investigated. The results show that in comparison to polythiophene and its other derivatives, PTTP has (i) the smallest band gap (scaled theoretical value of 0.5 eV) and (ii) greater tendency to form conducting materials on doping with both electron acceptors and electron donors. The effect of hetero substitution and the substituent at the carbon skeleton on the conduction properties of PTTP is discussed. (Edited author abstract) 17 refs.

**Microscopic Examination**

**094807 HIGH-RESOLUTION ELECTRON MICROSCOPY OF SOLUTION-GROWN CRYSTALS OF POLY(p-PHENYLENE SULPHIDE).** Crystals of poly(p-phenylene sulfide) were obtained from an  $\alpha$ -chloronaphthalene solution. The chain axis (the crystal c-axis) was usually normal to the support film. High resolution electron microscopic images were taken as the projection of the molecular chains on the ab plane along the chain axis. Occasionally it was observed that crystals took different orientations on the support film for undefined reasons. From such orientations, the high resolution image of a crystal rotated by  $28.7^\circ$  around the a-axis from the usual orientation was obtained. (Author abstract) 14 refs.

## Optical Properties

**094808 PHOTO-EXCITATION IN CONJUGATED POLYMERS.** Conjugated polymers such as polyacetylene form a group of model semiconductors in which the 'one-dimensional' character of the polymer strongly modifies the behavior of charges added to the chains from that usually observed in three-dimensionally bonded semiconductors. The motion of charged excitations is highly anisotropic, with strong confinement to the chain through the 'polaronic' structural relaxation of the chain. This anisotropy strongly affects charge transport and charge separation following photo-excitation. In this paper we some of the recent work in this area and we present polarization-dependent measurements of photoluminescence (PL) and photo-induced absorption (PA) on highly oriented films of polyacetylene and poly(phenylenevinylene). (Edited author abstract) 94 refs.

## Photoconductivity

**094809 DYNAMICS OF PHOTOGENERATED SOLITONS IN TRANS-POLYACETYLENE.** Time-resolved absorption using pole wavelengths of 2.5-5.5  $\mu\text{m}$  has been used to study photoexcitations in the quasi-one-dimensional semiconductor, trans-polyacetylene. Present apparatus has 0.5-ps resolution, which is sufficient to observe the decay of the photogenerated charged soliton pairs which form after intrachain excitation of electron-hole pairs. The tunability of the apparatus permits the unambiguous identification of solitons and observation of spectral relaxation during their formation. 21 refs.

## Synthesis

**094812 SYNTHESIS AND STUDIES OF POLY(3,9-CARBAZOLYL), A NEW CONDUCTIVE POLYMER DISPLAYING HIGH OPTICAL TRANSMITTANCE IN THE VISIBLE.** A polycarbazole consisting mostly of 3,9 linkages has been synthesized in a DMF solution by coupling 3,6-diiodocarbazole with an activated copper catalyst. Although this polymer cannot be oxidized by  $\text{I}_2$ , other acceptors such as iodine monochloride or NO will convert it to a p-type semiconductor with a conductivity as high as  $1\text{ ohm}^{-1}\text{ cm}^{-1}$ . A unique property of the oxidized polymer complex is that it displays a maximum transmittance in the visible at 600 nm and a broad near-i.r. band at 2300 nm. A large shift of the long-wavelength absorbance of the radical cation on the 3,9-linked polymer versus that found on the carbazole monomer suggests that a significant number of adjacent carbazole units are close to planarity. This must provide a significant pathway for electronic transport. (Edited author abstract) 26 refs.

**094813 CONDUCTING-POLYMER ELECTRONICS.** Polymers with electrical conductivities as good as those of metals are well known, but have yet to replace conventional electronic components because of difficulties in preparing and manipulating them. The development of soluble precursor polymers which can be unified and manipulated before being converted into a conductive form has invigorated the field. By using polyacetylene prepared by such a route, a research team at the Cavendish Laboratory in Cambridge has succeeded in fabricating polymeric semiconductor devices, transistors and diodes with characteristics superior to any previously reported. These devices operate via mechanisms intrinsically different from those in conventional semiconductor devices. Although the results obtained by this research team do not yet pose a threat to establish semiconductor technology, they offer the prospect of novel devices which cannot be constructed with conventional semiconductors.

**094814 NEW SEMICONDUCTOR DEVICE PHYSICS IN POLYMER DIODES AND TRANSISTORS.** Semiconductor devices have been made from polyacetylene, a conjugated polymeric semiconductor. The device operates in a novel way: charge is stored in localized soliton-like excitations of the polymer chain, which are introduced not by doping or photoexcitation but by the presence of a surface electric field. The formation of charged solitons changes the optical properties of the polymer, introducing optical absorption below the band gap. Combined with the processibility of the polymer, these new electrooptical effects may be exploited technologically in electrooptical modulators. (Edited author abstract) 22 Refs.

## SEMICONDUCTING SAMARIUM COMPOUNDS

### Elasticity

**094816 TEMPERATURE DEPENDENCE OF ELASTIC PROPERTIES OF  $\text{Sm}_{1-x}\text{Gd}_x\text{S}$  SINGLE CRYSTALS IN THE VICINITY OF THE —BLACK-GOLD— PHASE TRANSITION.** The temperature dependences of Young's modulus  $E_{100}$  and the lattice parameter have been studied in the temperature range 20 to 1000°C on  $\text{Sm}_{1-x}\text{Gd}_x\text{S}$  crystals with  $x=0$ , 0.14, and 0.18. The Gd concentration in the alloys was close to the critical one ( $x_c=0.16$ ). Under normal conditions a crystal of composition with  $x=0.14$  was in the black (semiconducting) phase whereas a crystal of composition with  $x=0.18$  was in the gold (metallic) phase. Young's, and shear moduli were measured by the resonance method. 11 refs.

Nikanorov, S.P. (USSR Acad of Sciences, Leningrad, USSR); Burenkov, Yu.A.; Lebedev, A.B.; Golubkov, A.V.; Zhukova, T.B.; Smirnov, I.A. *Phys Status Solidi A* v 105 n 2 Feb 1988 p K103-K106.

### Phase Transitions

**094817 SEMICONDUCTOR-METAL PHASE TRANSITION UNDER UNIAXIAL COMPRESSION OF  $\text{Sm}_{1-x}\text{Gd}_x\text{S}$  SINGLE CRYSTALS.** In SmS under a hydrostatic pressure of  $P_c=650\text{ MPa}$  a valency transition has been observed retaining the NaCl-type lattice and implying an essential reduction in the lattice constant. There are data stating that a similar transition in SmS and  $\text{Sm}_{0.85}\text{Gd}_{0.15}\text{S}$  can occur under uniaxial compression. The note deals with some peculiarities of such a transition in  $\text{Sm}_{0.86}\text{Gd}_{0.14}\text{S}$  crystals. The nuclei of the new phase appear due to stress concentrations at the specimen ends and their development takes place by the motion of misfit dislocations under the action of external stress. 8 refs.

## SEMICONDUCTING SELENIUM See Also SEMICONDUCTOR MATERIALS—Amorphous.

**Amorphous** See Also SEMICONDUCTING SILICON—Electronic Properties; SEMICONDUCTOR DIODES, PHOTODIODE—Ionization.

**094818 POLARIZED ELECTROABSORPTION SPECTRA OF AMORPHOUS SEMICONDUCTORS.** Transverse electroabsorption spectra of amorphous Se and hydrogenated amorphous Si (a-Si:H) are presented. These spectra are anisotropic, with fields  $F$  parallel to the polarization  $E$  of light, causing much larger signals than  $F$  perpendicular to  $E$ . At temperatures below 350 K the signal depends little on temperature. At higher temperatures the field-induced change  $\Delta\alpha$  depends on photon energy. At low energies the spectrum becomes isotropic and may arise from a quadratic Stark effect of tail states with rather large polarizabilities. The electroabsorption spectra cannot be explained by the Franz-Keldysh effect or by an exciton model. It is proposed that they arise from

field mixing of tail states which increases their dynamic polarizability. The mixing is most effective for states near the mobility edges. (Author abstract) 46 refs.

Weiner, G. (Fachbereich Physik der Univ Marburg, Marburg, West Ger); Dersch, U.; Thomas, P. *Philos Mag B* v 57 n 6 Jun 1988 p 721-735.

**094819 DENSITY OF STATE IN a-Se FROM COMBINED ANALYSIS OF XEROGRAPHIC POTENTIALS AND TRANSIENT TRANSPORT DATA.** The large-angle convergent-beam electron diffraction technique has been used to obtain 200 rocking curves from a  $1500 \text{ Al}_{0.4}\text{Ga}_{0.6}\text{As}/30 \text{ GaAs}/3500 \text{ Al}_{0.4}\text{Ga}_{0.6}\text{As}$  sample observed in plan view. It is demonstrated that the rocking curves are sensitive to the presence of the GaAs layer and are in good agreement with simulations calculated from a simple kinematical approach. It is shown that both the layer thickness and depth in the foil may be examined and that GaAs layer thicknesses less than 10 in the 5000 foil may be detectable. (Author abstract) 11 Refs.

## Charge Carriers

**094820 HOLE TRANSPORT IN SELENIUM-BASED AMORPHOUS XEROGRAPHIC PHOTO-RECEPTORS.** Xerographic time of flight (XTOF) and conventional time of flight (TOF) experiments were used to determine the response of various selenium-based amorphous monolayer photoconductors to short light pulses. From the observed flight time, the hole drift mobility,  $\mu_h$ , of charge carriers was deduced. For pure and lightly doped a-selenium, transient photocurrent signals at low field exhibit a decay during the time prior to transit time. This has been attributed to the loss of charge carriers from the propagation photoinjected charge packet and the time constant of the decay,  $\tau_h$ , has been taken as the hole lifetime. For a given composition, sample thickness, light intensity, substrate material and top contacts (in TOF only) were varied to ensure that the observed decay time constant  $\tau_h$  is a meaningful bulk parameter. Hole transport measurements support the assignment of  $\tau_h$  as hole lifetime.  $\mu_h$  and  $\tau_h$  were measured as a function of composition and applied field. Experimental data suggest that the hole transport mechanism is shallow trap controlled. Light doping of selenium with arsenic creates shallow traps and causes hole transport to deteriorate. Addition of chlorine promotes hole transport by increasing the lifetime but the hole drift mobility is reduced. Addition of tellurium in the range of 0-7 wt. percent progressively decreases hole drift mobility due to an increase in the density of the shallow traps. When chlorine is added to Se-Te alloys, it improves the hole transport by increasing  $\tau_h$  but the hole mobility falls. (Edited author abstract) 23 Refs.

## Diffusion

**094821 DIFFUSION OF SELENIUM AND TELLURIUM IN SILICON.** Diffusion of selenium and tellurium in silicon has been investigated in the temperature range 1000°C to 1310°C by sheet conductivity. For Si:Se  $D_0 = 0.3 \pm 0.1 \text{ cm}^2/\text{s}$  and  $h = 2.6 \pm 0.1 \text{ eV}$ , and for Si:Te  $D_0 = 0.9 \pm 0.3 \text{ cm}^2/\text{s}$  and  $h = 3.3 \pm 0.1 \text{ eV}$  have been obtained. The surface concentrations for both dopants were of the order of  $5 \times 10^{13}$  to  $6 \times 10^{16} \text{ cm}^{-2}$ . The Hall coefficient leads to an energy level of  $300 \pm 15 \text{ meV}$  for selenium and  $200 \pm 20 \text{ meV}$  for tellurium. (Author abstract) 16 Refs.

## Electric Properties

**094822 ELECTRICAL PROPERTIES OF AMORPHOUS SEMICONDUCTOR SELENIUM AND ITS ALLOYS: I. MONOLAYERS.** Various monolayer

a-Se-based photoreceptor devices were fabricated by vacuum evaporation and their electrical properties were investigated. Three experimental techniques, namely xerographic time of flight (XTOF), electroded time of flight (TOF) and xerographic discharge were used to determine the drift mobility, carrier lifetime, dark decay and residual voltage. Where possible, these measurements were carried out as a function of applied field and composition, namely As approx. 0.3 wt%, Te up to 17 wt% and Cl up to 60 ppm. The addition of As or Te alone reduced both hole and electron drift mobilities and increased the carrier lifetime. Both XTOF and TOF experiments showed a trap-limited response for electron transport in Se+Cl and Se:Te+Cl systems. The addition of As was found to restore the electron response in these photoreceptors. From the charge transport data and saturated residual voltage measurements, the hole capture coefficient in a-Se was estimated to be about  $1.0 \times 10^{-8} \text{ cm}^3 \text{ s}^{-1}$ . (Edited author abstract) 58 refs.

## Photochemical Reactions

**094823 PHOTOELECTROCHEMISTRY IN PARTICULATE SYSTEMS. 8. PHOTOCHEMISTRY OF COLLOIDAL SELENIUM.** Selenium which exists in both crystalline and amorphous forms is an n-type semiconductor with a broad range of applications. Optical and photoelectrical properties of different forms of selenium have already been studied. In authors' continuing efforts to probe the corrosion processes of metal chalcogenides they have recently reported the laser flash photolysis and pulse radiolysis study of CdSe and  $\text{In}_2\text{Se}_3$  colloids. A major product of photoanodic corrosion of these semiconductors is elemental Se, which could be identified by the changes in the absorption spectrum. Se formed during the anodic corrosion process either exists in the colloidal form or precipitates on the surface of colloidal CdSe and  $\text{In}_2\text{Se}_3$ . The presence of Se, which is also photoactive, can influence the photoelectrochemical behavior of colloidal metal selenides. In view of this the authors have prepared colloidal particles of red amorphous Se in aqueous solution, and its photochemical and photoelectrochemical behavior is described here. 18 refs.

Dimitrijevic, Nada M. (Univ of Notre Dame, Notre Dame, IN, USA); Kamat, Prashant V. *Langmuir* v 4 n 3 May-Jun 1988 p 782-734.

## Thin Films

**094824 CRYSTALLIZATION AND MELTING OF  $\text{Se}_{0.99}\text{Bi}_{0.01}$  THIN FILMS BY MEANS OF D.T.A. TECHNIQUE.** The thermal properties of amorphous chalcogenide semiconductors can be changed by addition of some impurities: the effects of various kinds of foreign atoms on thermal phenomena have been studied. The  $\text{Se}_{0.99}\text{Bi}_{0.01}$  thin films deposited on aluminium and kapton substrates either by flash or by thermal evaporation have been characterized by means of the differential thermal analysis technique (D.T.A.). This paper deals with crystallization and melting of such films. Furthermore, in order to determine the activation energy associated with the crystallization and the frequency factor, three methods are considered. The values obtained do not vary more than 10%. The nature of the substrate and the method of evaporation seem to modify the thermal behavior. It is worth noting that a sharper peak of crystallization occurs in the case of  $\text{Se}_{1-x}\text{Bi}_x$  deposited on kapton substrates due to the small size of crystals. (Edited author abstract) 11 refs.

Atmani, H. (Lab d'Etude des Couches Minces Amorphes et Polycristallines, Mont-St.-Aignan, Fr). *Mater Chem Phys* v 19 n 3 Apr 1988 p 255-266.

## Amorphous

**094825 ELECTRICAL CONDUCTION IN AMORPHOUS  $\text{Cu}_{10}\text{As}_{40}\text{Se}_{50}$  WITH POTENTIAL FLUCTUATIONS.** Hall measurements of amorphous and annealed  $\text{Cu}_{10}\text{As}_{40}\text{Se}_{50}$  samples are performed to evaluate the carrier density and to evaluate the mobility in the temperature range 300 to 580 K. It is found that the free hole density  $p_f$ , the Fermi level, and the mobility are functions of the annealing processes. The data are interpreted using the potential fluctuation theory. Differential thermal analysis (DTA) is performed. The endothermic changes of DTA have been attributed, in fact, to the shrinkage of the maximum height of the potential hills with temperature; while the exothermic changes have been regarded as a reason of the reduction of the disorder energy with annealing. (Author abstract) 12 refs.

Abdalla, S. (Qena-Asiut Univ, Asut, Egypt); Dongol, M.; Ibrahim, M.M. *Phys Status Solidi B* v 144 n 2 Dec 1987 p 745-752.

**094826 DECAY OF PHOTOCONDUCTIVITY IN AMORPHOUS  $\text{As}_2\text{Se}_3$  FOLLOWING REPETITIVE-PULSE EXCITATION.** Experimental results are presented for the decay of photoconductivity in amorphous  $\text{As}_2\text{Se}_3$  following single-pulse, repetitive-pulse and steady-state illumination, at various temperatures. The observed decays are compared with calculations using a discretized density of band-tail states decaying exponentially into the band gap. The connection between the decays after repetitive-pulse and steady-state illumination is described. It is shown that agreement between calculation and experiment requires a band tail which extends deep into the band gap, and that the presence of a deep band tail can be inferred from measurements made on relatively short time scales. (Author abstract) 21 refs.

Wolverson, D. (Univ of Exeter, Exeter, Engl); Phillips, R.T. *Philos Mag B* v 57 n 5 May 1988 p 635-647.

**094827 ELECTRICAL PROPERTIES OF THE AMORPHOUS SEMICONDUCTING Se-Te-In SYSTEM.** The measurement of DC electrical conductivity and thermoelectric power of the bulk samples of chalcogenide glasses of the system  $\text{Se}_{70-x}\text{Te}_{30-x}\text{In}_x$  ( $x=1, 3, 5, 7, 9\%$  atomic weight) are studied. The activation energies are obtained from conductivity and thermoelectric power measurements, using Mott, Davis and Fritzsche equations. The difference of activation energies  $E_0 = E_\sigma - E_s = 0.12 \text{ eV}$  is explained on the basis of long range electrostatic potential fluctuations, and this difference in activation energies is in agreement with the results reported by Overhof and Beyer for the chalcogenides. And it has also been observed that addition of indium in the samples increases the electrical conductivity. (Author abstract) 19 Refs.

Gadkari, A.B. (Shivaji Univ, Kolhapur, India); Zope, J.K. *J Non Cryst Solids* v 103 n 2-3 Jul 1988 p 295-299.

**094828 SHORT-RANGE ORDERED STRUCTURE IN AMORPHOUS SELENIUM FILMS BY X-RAY RADIAL DISTRIBUTION FUNCTION ANALYSIS.** By the word 'Structure' we would mean the short-range order (SRO) as well as the structural and compositional inhomogeneities. In this presentation, the SRO structure will be analyzed in vapour-deposited amorphous selenium films considering the radial distribution function (RDF), which is a Fourier transform of the X-ray diffractogram data recorded in a counter-diffractometer equipped with LiF monochromator. In applying RDF, various corrections are to be made and these are to be dealt with critically so as to evaluate the structural arrangement in a more reasonable manner. This presentation is concerned

with the development and applications of the correction procedures in vapour-deposited a-Se films. (Edited author abstract)

## Crystallization

**094829 ZONAL RECRYSTALLIZATION OF SUPERIONIC  $\text{Cu}_{2-x}\text{Se}$  IN THE SOLID STATE.** Investigations were conducted into the redistribution of mobile copper in specimens of a nonstoichiometric semiconductor compound of copper selenide  $\text{Cu}_{2-x}\text{Se}$  during their zonal recrystallization in the solid state in the vicinity of the superionic phase transition ( $T_c = 291-413$  K). The superionic phase transition in  $\text{Cu}_{2-x}\text{Se}$  is complicated and includes the transformations of the eutectoid and peritectoid type, and the coefficient of diffusion of mobile copper ion in the material gives a value comparable with the diffusion coefficients in the liquid. (Edited author abstract) 6 refs.

## Growth

**094831 METAL-ORGANIC VAPOUR PHASE EPITAXIAL GROWTH AND CHARACTERIZATION OF WIDE BAND-GAP II-VI MATERIALS.** Recent progress in metal-organic vapour phase epitaxial growth and characterization of the wide band-gap II-VI materials  $\text{ZnSe}$ ,  $\text{ZnSe}_{1-y}\text{S}_y$  ( $0 < y < 1$ ) and  $\text{ZnS}$  is described. Attention is focussed on the nature of interfaces when these materials are grown on single crystalline III-V semiconductors where, in most cases, there is a lattice-mismatch between the epitaxial layer and substrate. The superior characteristics of the lattice-matched ternary  $\text{ZnSe}_{0.95}\text{S}_{0.05}$  grown on GaAs are highlighted. Difficulties with doping studies are indicated and future lines of research are outlined. (Author abstract) 26 refs.

Williams, J.O. (UMIST, Manchester, Engl). *Chemtronics* v 2 n 2 Jun 1987 p 43-48.

## Mechanical Properties

**094832 VARIATION OF THE MICROHARDNESS OF COPPER SELENIDE DURING THE TRANSITION TO THE SUPERIONIC PHASE.** A study was made of the microhardness of  $\text{Cu}_{2-x}\text{Se}$  samples ( $x = 0-0.3$ ) in the 220-470 K temperature range. An anomalous decrease in the microhardness of the samples

was observed during the transition to the superionic  $\beta$ -phase ( $T_c = 291-413$  K). This anomalous decrease is attributed to a singular state of the superionic phase which is intermediate between solid and liquid. In Russian. 8 refs.

## Optical Properties

**094833 EFFECT OF CHLORINE ON XEROGRAPHIC PROPERTIES OF a-SE:Te ALLOYS.** Amorphous selenium (a-Se) has an optical bandgap of 2.1 eV and a photogeneration efficiency close to unity at 2.7 eV which makes it sensitive to the blue region of the visible spectrum. Alloying with tellurium reduces the bandgap and increases the photosensitivity towards higher wavelengths. Experimental results have already been reported to show that charge acceptance, residual voltage, dark decay rate and drift mobility are sensitive to tellurium. Charge acceptance and carrier drift mobilities decrease with tellurium whereas dark decay rate increases. All these effects are undesirable in xerography. Transient photoconductivity and residual voltage measurements were carried out to investigate the effect of a small chlorine addition on the xerographic properties of a-Se:Te alloys. Chlorine improves the residual voltage and charge acceptance. Transient photoconductivity data on hole transport shows that the xerographically important parameter of carrier range is also improved. The results are interpreted in the framework of shallow trap controlled transport. (Edited author abstract) 16 refs.

## Photoconductivity

**094834 STEADY STATE AND TRANSIENT PHOTOCONDUCTIVITY IN AMORPHOUS THIN FILMS OF  $\text{Se}_{0.8}\text{Te}_{0.2}$ .** The present paper reports on steady state and transient photoconductivity measurements in amorphous thin films of  $\text{Se}_{0.8}\text{Te}_{0.2}$ . The paper also reports the effect of crystallization on the photoconductive behavior. The photosensitivity ( $I_{ph}/I_d$ ) reduces by a factor of 5 and the decay of photocurrent becomes much slower in the films annealed above the crystallization temperature (state B) as compared to the films annealed below the crystallization temperature (state A). A detailed analysis of the photoconductive decay in the state B shows that the recombination within localized states may be the predominant recombination mechanism in this state. (Author abstract) 22 refs.

## Switching

**094835 THRESHOLD SWITCHING EFFECTS IN  $\text{Ag}_2\text{TeSe}_2$  AND  $\text{CuTeSe}_2$  FILMS.** Switching effects in  $\text{Ag}_2\text{TeSe}_2$  and  $\text{CuTeSe}_2$  chalcopyrite semiconductors films have been investigated. The threshold switching voltage was found to increase linearly with the thickness, more-over  $V_{th}$  increases exponentially with the temperature. The rapid transition between the highly resistive and conductive states was attributed to an electrothermal origin from Joule's heating of a current channel. (Author abstract) 11 refs.

Affifi, M.A. (Ain Shams Univ, Cairo, Egypt); Labib, H.H.A.; Abou El Ela, A.H.; Sharaf, K.A. *Appl Phys A* v 44 n 2 Jun 1988 p 113-117.

## Synthesis

**094836 CRYSTAL STRUCTURE OF COPPER IODIDE TRISELENIDE  $\text{CuISe}_3$ , A REACTANT IN AN**

**n-CuInSe<sub>2</sub> BASED SOLAR CELL.** The crystal structure of  $\text{CuISe}_3$  has been determined.  $\text{CuISe}_3$  is a rhombohedral crystal with space group  $R\bar{3}m$  and lattice parameters  $a = 1407.9(6)$  pm,  $c = 1418.7(2)$  pm (hexagonal setting). The structure consists of six-membered Se rings in chain-type configuration, which are surrounded by rhombuses of  $\text{Cu}_2\text{I}_2$  units oriented parallel to the c-direction and alternating in height. A comparison with the crystal structure of  $\text{CuBrSe}_3$  is given. (Edited author abstract) 14 refs.

**094837 KINETIC STUDY OF THE FORMATION OF COPPER SELENIDES BY COPPER SELENIZATION.** Copper-selenium compounds have received considerable attention in recent years due to their potential application in semiconducting systems. Copper electrodeposits of different thicknesses were obtained on titanium plates and corroded by a selenization process in selenous acid solutions. The change in the open circuit potential with time was followed and the records show one or two plateaus at different potential values. The transition times measured on those plateaus and their variations with selenous acid, proton and  $\text{Cl}^-$  ion concentrations, as well as with temperature were measured. Kinetic parameters were deduced, which allowed the formulation of reaction mechanisms for the copper corrosion reactions occurring on both plateaus. SEM micrographs and analysis of the obtained deposits and of the solutions resulting from the corrosion processes confirmed the postulated mechanisms. The most likely compounds formed were  $\alpha\text{-Cu}_2\text{Se}$  for high reaction rates and  $\alpha\text{-CuSe}$  mixed with  $\text{Cu}_{1.8}\text{Se}$  and  $\text{Cu}_{2-x}\text{Se}$  for slower rates. (Edited author abstract) 11 refs.

**094838 CRYSTAL GROWTH AND CHARACTERIZATION OF  $\text{Mn}_x\text{Cd}_{1-x}\text{Ga}_2\text{Se}_4$ : A NEW FAMILY OF DILUTED MAGNETIC SEMICONDUCTORS.** Crystals of  $\text{Mn}_x\text{Cd}_{1-x}\text{Ga}_2\text{Se}_4$  ( $0.00 \leq x \leq 1.00$ ) were grown from the vapor phase by chemical transport, and all the samples were found to crystallize in the tetragonal defect chalcopyrite structure, space group  $I4^-$ . X-ray investigations suggested that  $\text{Mn}^{2+}$  ions replace  $\text{Cd}^{2+}$  ions on 2b positions of the lattice. EPR spectra were examined as a function of temperature and of the composition x. Evidence is presented that the magnetic interactions between manganese ions are predominantly antiferromagnetic down to  $T = 90$  K. (Edited author abstract) 20 refs.

**094840 RECLAIMED SILICON WAFERS AND SURFACE CONTAMINATION: A COMPARATIVE STUDY.** The study presented demonstrates the potential of SSIMS analysis for probing and evaluating silicon surface contamination. Though direct quantitation is very difficult, comparisons of contaminants to matrix-ion intensities can produce reproducible ratios for use in comparing different materials. In terms of the levels of cleaning contaminants on wafers, the study clearly shows that the cleanliness of reclaimed wafers compares favorably with that of virgin silicon surfaces. Thus, the use of reclaims as process monitors should not result in a greater potential for product cross-contamination. 6 refs.

**094841 INTERACTION BETWEEN LOCALIZED AND DELOCALIZED STATES INDICATED FROM TEMPERATURE-DEPENDENT ESR STUDY OF SUBMETALLIC P-DOPED SI.** A K-band electron spin resonance (ESR) analysis has been carried out on submetallic Si:P powders containing  $(1.7 \pm 0.1) \times 10^{18}$  P atoms  $\text{cm}^{-3}$ . As expected, only one signal, generally referred to as the central pair line (CPL), is observed. Accurate data of the peak-to-peak linewidth  $\Delta B_{pp}$  and g-value are presented for the temperature range  $1.6 \text{ K} \leq T \leq 300 \text{ K}$ . The implication of the experimental results regarding the physical model of the P-in-Si behavior is discussed. In the range  $\leq 4.2 \text{ K}$ , comparison to other data reveals the existence of a significant different T dependence of g and  $\Delta B_{pp}$  between the high and low observational-frequency situations. In the higher T range, the data are indicative of the presence of an s-d like interaction between localized donor spins and delocalized electrons, which gradually increases with T. (Edited author abstract) 27 refs.

**094842 ENERGY BAND DIAGRAM OF THE a-Si:H/c-Si INTERFACE AS DETERMINED BY INTERNAL PHOTOEMISSION.** The internal photoemission of electrons from the valence band of crystalline silicon into the conduction band of amorphous hydrogenated silicon has been studied experimentally. The photoemission process in the case of the interface between two

semiconductors raised specific problems in the treatment of data, and these are analyzed. The results indicate that the energy difference between the amorphous and crystalline valence band edges at the interface is close to zero, and is not affected by the hydrogen-induced widening of the optical gap in amorphous silicon. (Author abstract) 17 refs.

**094845 HYDROGENATED AMORPHOUS SILICON FILMS OBTAINED BY A LOW PRESSURE DC GLOW DISCHARGE.** Films of a-Si:H have been deposited by means of a dc hot cathode discharge of  $\text{SiH}_4$  with electrostatic confinement at a pressure as low as 0.4 Pa. The plasma used is quite quiescent as has been observed by means of reproducible Langmuir probe measurements. Substrates have been placed at different locations in between the electrodes, some of them facing the anode and the others facing the cathode. Films deposited on substrates facing the cathode present a granular, non-columnar, structure, an IR spectrum with only SiH absorption peaks, and a very low photoresponse. Films deposited on substrates facing the anode have a similar IR spectrum but are homogeneous, have lower hydrogen content, and present a high photoresponse. (Edited author abstract). 24 Refs.

## Ablation

**094846 ULTRAVIOLET LASER ABLATION OF A SILICON WAFER.** Pulsed laser irradiation at 248 nm can ablate Si atoms from a Si(100) wafer. The mechanism of this photoablation has been examined by a laser-induced fluorescence analysis of the Si products. The measured Si atoms were shown to leave the wafer surface with an average translational energy of 2.5 kcal/mol. The distribution of the translational energy is well described by a theoretical model for non-cascade ablation processes. (Author abstract) 8 refs.

## Absorption

**094847 SEMIEMPIRICAL CNDO INVESTIGATIONS OF H, F AND Cl CHEMISORBED ON Si (111).** In a previous paper, the semiempirical CNDO SCF molecular orbital method has been applied to clusters  $\text{X}_3$ ,  $\text{X}'_{12}$  modeling covalent semiconductors. X and X' stand for semiconductor atom and the corresponding fictitious one, respectively. The results obtained from CNDO/2 calculations can be used to describe the properties of silicon, diamond and germanium, after redetermining the bonding parameters and choosing the reasonable electronegativities of boundary atoms. We report the results of H, F and Cl chemisorbed on Si(111). These results are obtained by use of the mentioned calculating scheme. Comparing with the results of other theoretical calculations, it is shown that our calculating scheme is also suitable for studying chemisorptions on covalent semiconductor surfaces. ## Acoustic Wave Effects

**094848 PERTURBATION OF SAW PHASE VELOCITY IN THE n-Si/YZ-LiNbO<sub>3</sub> STRUCTURE.** The overall phase velocity change of SAW for n-Si thin layer on YZ-LiNbO<sub>3</sub> substrate is calculated considering mechanical and electrical perturbations in the case of low-kd limit. The mechanical perturbation is modified to include the dependence of electron concentration in Si. The variation of overall SAW velocity with electron concentration, layer thickness, and frequency show markedly different dependence from that of both mechanical and electrical perturbations. The rapid decreases of overall SAW velocity at low and high electron concentrations are attributed to electrical perturbation and carrier concentration effect on mechanical perturbation respectively. (Author abstract) 25 refs.

## Adsorption

**094849 SELF-CONSISTENT CALCULATION OF BOND ORBITAL FOR OXYGEN ADSORPTION ON Si SURFACE.** A self-consistent calculation of bond orbital, which takes the variation of atomic wave functions by charge transfer into account is proposed for the investigation of oxygen adsorption on Si(111) surface. In the head-on position adsorption model, a suitable selection of bond length can produce the relative energies of all main peaks in the valence band photoelectron emission spectra. The results indicate the bond length between Si and O atoms is not close to that in  $\text{SiO}_2$  as usually conjectured, but a little less than that of Si-Si bond in bulk. The calculations also gives the energy of Si-O bond under the surface after oxidation. (Author abstract) 16 refs. In Chinese.

**094850 MICROWAVE-EXCITED PLASMA CVD OF a-Si:H FILMS UTILIZING A HYDROGEN PLASMA STREAM OR BY DIRECT EXCITATION OF SILANE.** The microwave-excited plasma CVD of a-Si:H films, in which SiH<sub>4</sub> was decomposed by a plasma stream of hydrogen or by direct excitation at low pressures ( $10^{-4}$  to  $10^{-3}$  Torr), was examined and compared with a previously studied Ar plasma stream method. It was clarified that an Ar plasma stream was not necessary to obtain highly photoconductive a-Si:H films. However, the deposition characteristics in these deposition methods were different from the Ar plasma stream method. On the other hand, the influence of the hydrogen plasma stream was not apparent when the SiH<sub>4</sub> flow rate was high, suggesting an ionization cross-section dependence of the plasma discharge. (Author abstract) 14 refs.

Watanabe, Takeshi (Hitachi Ltd, Yokohama, Jpn); Tanaka, Masahiro; Azuma, Kazufumi; Nakatani, Mitsuo; Sonobe, Tadashi; Shimada, Toshikazu. *Jpn J Appl Phys Part 1* v 26 n 8 Aug 1987 p 1215-1218.

**094851 HYDROGEN DIFFUSION IN AMORPHOUS SILICON.** Hydrogen diffusion in doped and compensated a-Si:H has been measured by secondary-ion mass spectrometry profiling in the temperature range 155-300°C. Doping reduces the activation energy and enhances the diffusion coefficient by up to three orders of magnitude at 200°C, and a correlation between the diffusion coefficient and the dangling-bond density is found. An analysis of three different diffusion models indicates that the breaking of weak Si-Si bonds by hydrogen may be an important process. The relation between the diffusion results and the thermal equilibration of the electronic structure is discussed. (Author abstract) 21 refs.

Street, R.A. (Xerox Palo Alto Research Cent, Palo Alto, CA, USA); Tsai, C.C.; Kakalios, J.; Jackson, W.B. *Philos Mag B* v 56 n 3 Sep 1987 p 305-320.

**094852 DENSITY OF STATES OF SPUTTERED a-Si:H STUDIED BY THE SPACE-CHARGE-LIMITED CURRENT TECHNIQUE. THE INFLUENCE OF DEPOSITION PARAMETERS, LIGHT AND keV-ELECTRON IRRADIATION.** The space-charge-limited current (SCLC) technique has been used to determine the density of states (DOS) near the Fermi level for a-Si:H films prepared by magnetron sputtering under various experimental conditions. From a study of the thickness dependence it can be concluded that surface or interface states might significantly contribute to the DOS. A minimum DOS of  $5.5 \times 10^{15} \text{ cm}^{-3} \text{ eV}^{-1}$  at  $E_c - E = 0.75 \text{ eV}$  was determined for well passivated films. The generation of metastable defects by light soaking and keV electron irradiation has been directly observed by the change in the DOS. For the same energy deposited, defect creation by electrons is a factor of 3300 higher than that by light. In addition, the generation process is found to be different. A model is suggested that explains the creation of defects by electrons via a direct electronic excitation process. (Author abstract) 44 refs.

Gangopadhyay, S. (Univ Kaiserslautern, Kaiserslautern, West Ger); Schroeder, B.; Geiger, J. *Philos Mag B* v 56 n 3 Sep 1987 p 321-333.

**094853 DEPOSITION OF a-Si:H BY MAGNETRON SPUTTER-ASSISTED PLASMA-CVD: PREPARATION AND PHYSICAL PROPERTIES.** Thin a-Si:H layers were deposited by sputter-assisted plasma (SAP)-CVD. The magnetron used combines the sputter technique with the plasma-assisted CVD and enables to shift the deposition from sputtering over SAP-CVD to the pure PCVD regime by variation of the process parameters. The physical properties (deposition rate, dark and photoconductivity, ESR and IR absorption) of the layers have been correlated with the deposition regime and the special process parameters for finding out the optimal deposition parameters in the SAP-CVD regime. The dependence of the growth rate on the growing regime has been described by a model based on a linear superposition of the partial growth rates in the sputtering and PCVD regime. (Edited author abstract) 14 refs.

**094854 LIGHT-INDUCED CHANGES IN THE FIELD-EFFECT CONDUCTANCE OF HYDROGENATED AMORPHOUS SILICON.** The effects of illumination with white light and annealing to 180-200°C on the field-effect conductance of a-Si:H FETs have been investigated. The effects produced by illumination are completely reversed by annealing. We find that illumination produces two types of change in the field-effect conductance; first, a maximum decrease in the off-conductance of about 300%, with a positive shift of the threshold voltage, and secondly a horizontal displacement of the conductance characteristic in the pre-threshold region with no change in the off-conductance. In both cases there is a movement of the bulk Fermi level with respect to the conduction band mobility edge. These two effects may be produced in a single silicon film sample. (Author abstract) 10 refs.

**094856 DOPING EFFICIENCY IN R.F.-SPUTTERED HYDROGENATED AMORPHOUS SILICON.** The efficiency of B and As in gas-phase doping of hydrogenated amorphous silicon (a-Si:H) prepared by r.f. sputtering has been experimentally evaluated. The dopant incorporation, i.e., the solid-phase concentration, was found to be linear with gas-phase concentration for both dopants, and independent of the substrate temperature. The creation of defects with doping has been investigated by electron spin resonance and photothermal deflection spectroscopy. The results suggest that a dangling bond is created for each fourfold-coordinated dopant atom, in agreement with the general concept of the modified 8-N rule. However, the variations of the doping efficiency with the solid-phase concentrations differ from the expected values. It is concluded that the laws of mass action cannot be applied under conditions of sputtering and that the incorporation of dopant atoms occurs in a non-equilibrium process at the growing surface. (Edited author abstract) 17 refs.

**094857 TRANSITION FROM DIFFUSIVE TO BALLISTIC CAPTURE RELATED TO HYDROGEN INCORPORATION IN AMORPHOUS SILICON.** We have shown in previous work that, in triode dc sputtered amorphous silicon, the value of the capture cross-section  $\sigma$  of deep gap states depends strongly on the hydrogen content of the material. Here we analyze the influence of such an effect on the transport properties of a set of samples whose hydrogen content  $C_H$  varies between 8 and 20%. For this purpose, we have measured at room temperature the mobility-lifetime product for electrons,  $\mu_n \tau_n$ , the density of states at the Fermi level  $N(E_F)$  and the defect density  $N_d$  derived from photothermal deflection

spectroscopy experiments. Log-log plots of the  $\mu_n \tau_n N(E_F)$  and  $\mu_n \tau_n N_d$  products against  $\sigma$  show two regimes with a transition corresponding to a hydrogen content of about 12%. These two regimes are related to different modes of capture controlled either by a diffusive process (low  $C_H$ ) or by a ballistic process (high  $C_H$ ). (Edited author abstract) 14 refs.

**094858 MOBILITY-LIFETIME ESTIMATES IN AMORPHOUS HYDROGENATED SILICON (a-Si:H).** Estimates of the majority photocarrier mobility-lifetime ( $\mu\tau$ ) product obtained from time-of-flight transient photoconductivity and from steady-state photoconductivity are compared. It is shown that in principle both experiments measure the integral of the transient drift mobility. Estimates of  $\mu\tau$  for undoped amorphous hydrogenated silicon (a-Si:H) based on the two techniques disagree by a factor of approximately 100 in comparable specimens. Possible origins of the discrepancy are discussed in relation to experimental procedures, optical bias effects and surface inhomogeneity. It is concluded that in undoped a-Si:H the dangling-bond defect observed in electron-spin resonance acts predominantly as a photocarrier trap and not as a simple recombination center. (Edited author abstract) 14 refs.

**094859 MICROSCOPIC MOBILITY IN HYDROGENATED AMORPHOUS SILICON.** It has recently been proposed that the electron microscopic mobility in hydrogenated amorphous silicon is of the order of  $100 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ , and that the observed lower mobility values result from scattering by potential fluctuations arising from defect centers which have a negative effect correlation energy. We show that such potential fluctuations cannot lower the mobility to its observed value of  $10 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ . Moreover, we find that the experimental evidence used to support the claim of a higher mobility can be adequately explained by the lower of the accepted values. (Author abstract) 17 refs.

Kakalios, J. (Xerox Palo Alto Research Cent, Palo Alto, CA, USA). *Phil Mag Lett* v 55 n 3 Mar 1987 p 129-134.

**094860 ENERGY LEVELS OF DANGLING-BOND CENTRES IN a-Si:H STUDIED BY PHOTOCAPACITANCE TRANSIENT SPECTROSCOPY.** The energy level spectrum of gap states in P-doped a-Si:H has been determined using photo-isothermal capacitance transient spectroscopy (ICTS) with sub-bandgap excitation. Photocapacitance transients were observed in the range from the bandgap energy down to 0.5 eV. It has been deduced that two gap-state features exist in the mobility gap; one is 0.5-0.6 eV below the mobility edge ( $E_c$ ) of the conduction band, and the other 1.0-1.2 eV below  $E_c$ . These results are consistent with our previously reported results on ICTS as well as with defect PL, which were explained in terms of 'isolated' and 'charge-coupled' doubly occupied dangling bonds ( $D^-$ ,  $D^+$ ). (Author abstract) 27 refs.

**094861 TRANSIENT PHOTOCONDUCTIVITY IN N-TYPE a-Si:H.** The long-time transient photocurrent decay in annealed and light-exposed P-doped a-Si:H is examined experimentally and by numerical modeling. The decay is a dispersive power law with sublinear index, extending to times longer than 1s, and the decay rate increases with temperature. Light exposure dramatically decreases the decay amplitude but does not affect the rate of decay. The phenomenon is discussed in terms of a comprehensive multiple-trapping model in which transport of thermalized electrons is essentially non-dispersive, and recombination of free carriers via defects is dispersive,

owing to continued thermalization of excess holes. The index of the excess photoelectron decay provides information on the valence-band tail states, which are exponentially distributed, with a characteristic energy estimated as 0.06 eV. (Edited author abstract) 22 refs.

**094862 INFLUENCE OF MECHANICAL STRESS ON LIGHT-INDUCED CREATION OF DEFECTS IN HYDROGENATED AMORPHOUS SILICON.** The effect of mechanical stress on light-induced changes in photoconductivity has been studied in films of plasma-deposited hydrogenated amorphous silicon on different substrates. The experimental results reveal no correlation between the degradation of the photoconductivity and the mechanical stress in these films. These findings contradict the observations of M. Stutzmann but agree with those of S. Guha et al. (Author abstract) 9 refs.

**094864 FREQUENCY-DEPENDENT LOSS IN SANDWICH SAMPLES OF HYDROGENATED AMORPHOUS SILICON.** Measurements of the a.c. conductivity of intrinsic sandwich samples of a-Si:H with  $n^+$  contact layers made between 1.3 and 360 K are described. Effects arising from the series impedance of the  $n^+$  layers are described by a simple geometrical model, demonstrating that the losses observed are representative of the bulk material. At low temperatures, the loss is small and fairly independent of temperature, but above 80 K it increases rapidly with temperature. The low-temperature loss is ascribed to deep states, and that occurring at higher temperatures to band-tail relaxation. Evidence in favor of this view is presented from the changes in loss observed under illumination. (Author abstract) 13 refs.

**094865 INTERPRETATION OF THE LOW-TEMPERATURE PHOTOCONDUCTIVITY IN a-Si.** The paper is concerned with the interpretation of steady-state photoconductivity results on undoped a-Si at temperatures of 50 K and below which lead to an essentially constant value of the (photogeneration efficiency  $\times$  mobility  $\times$  lifetime) product  $\eta\mu\tau \approx 10^{-11} \text{ cm}^2\text{V}^{-1}$ . Measurements on  $p^+i-n^+$  junctions and Cr- $i-n^+$  barriers were carried out to determine the parameters separately: (i) steady-state reverse saturation currents gave a generation efficiency of  $\eta \approx 5 \times 10^{-2}$  below 50 K, suggesting that geminate recombination limits the generation process; (ii) the electron drift mobility  $\mu_e$  through the tail states and the charge extracted from the absorption region of the incident light were investigated by transient experiments, these showed that  $\mu_e\tau_a$  is limited to about  $3 \times 10^{-10} \text{ cm}^2\text{V}^{-1}$  at low T. (Edited author abstract) 9 refs.

**094866 STAEBLER-WRONSKI EFFECT IN a-Si:H FILMS IMPLANTED WITH BORON AND PHOSPHORUS IONS.** It is established in experiments in a-Si:H films implanted with boron and phosphorus ions that with total concentrations of the implanted B and P ions  $N_B$  and  $N_P$  of less than  $5 \cdot 10^{19} \text{ cm}^{-3}$  the Staebler-Wronski effect, a change in the dark conductivity and

its energy of activation after illumination of the films by white light, is observed. At  $N_B, N_P > 5 \cdot 10^{19} \text{ cm}^{-3}$  there is no such effect. The nature of the observed patterns is discussed. (Author abstract) 11 refs.

**094867 EXPERIMENTAL DETERMINATION OF THE DENSITY OF GAP STATES IN AMORPHOUS SILICON BY SCHOTTKY BARRIER ADMITTANCE.** Experimental admittance measurements are presented for an n-type doped amorphous-silicon Schottky barrier. The measurements are shown to be quite consistent with the theory described by I.W. Archibald and R.A. Abram and, using this theory, an estimate of the density of states in the upper half of the mobility gap is calculated. The average value is approximately  $10^{17} \text{ cm}^{-3} \text{ eV}^{-1}$ , and there is a minimum situated approximately 0.4 eV below the conduction-band mobility edge. The test-fit value for the gap-state capture/emission time constant  $\tau_0$  is found to be  $10^{-12} \text{ s}$ . (Edited author abstract) 16 refs.

**094868 THERMALIZATION AND RADIATIVE RECOMBINATION OF PHOTO-EXCITED CARRIERS IN a-Si:H.** The thermalization and recombination of photo-excited carriers in a-Si:H have been studied by transient photoluminescence. The time decay of the photoluminescence after pulsed photo-excitation was measured for temperatures between 50 and 120 K and for different optical bias intensities. It is shown that the experimental results can be understood in the framework of an extended multiple-trapping model which, in contrast to the conventional multiple-trapping model, allows for transitions between the localized tail states and for electron-hole recombination. Thus, the model presented can be understood as a first step toward a common description of the transient optical and transport properties of a-Si:H. The validity of the basic assumptions made in the conventional multiple-trapping model as well as in our extended version are discussed, and possible extensions are pointed out. (Author abstract) 17 refs.

**094869 OPTICAL CHARACTERIZATION OF UNDOPED a-Si:H PREPARED BY PHOTO-CVD AND GD TECHNIQUES.** We have optically characterized undoped a-Si:H films prepared by photo-CVD and GD techniques under various deposition conditions. Photoluminescence (PL) and transmission spectra were measured at 77 K, from which the peak energy  $E_p$  of the main PL band and the optical absorption edge  $E_{opt}$  could be deduced. We have obtained the Urbach energy  $E_0$  by means of photothermal deflection spectroscopy (PDS) at room temperature. The differences  $\Delta E$  between  $E_p$  and  $E_{opt}$  were plotted against  $E_0$  for films prepared under various conditions, from which it was found that the same linear relation holds between  $\Delta E$  and  $E_0$  commonly for films prepared by both techniques. We conclude that the increase of  $\Delta E$  in films deposited at a low substrate temperature is mainly caused by a broadening of the tail states owing to disorder in the amorphous network. (Author abstract) 8 refs.

**094870 LIGHT-INDUCED EFFECT OF a-Si FILMS FABRICATED USING THE SUPER CHAMBER.** The light-induced effect in a-Si films with low impurity concentrations fabricated in the super chamber was investigated. It was confirmed that a reduction of impurity reduces the light-induced effect over a range of more than  $10^{18} \text{ cm}^{-3}$  for oxygen. Furthermore, other factors come to have an influence on the light-induced effect in the

low-impurity region. We believe that there are at least two types of light-induced defects, one related to impurities, which may be located below the midgap, and one related to structural properties, which may be located around the midgap. For a further reduction of the light-induced degradation in a-Si films, it is necessary to reduce the impurities in a-Si films and to suppress the creation of dangling bonds around the midgap. **094871 ON THE REACTION KINETICS IN A MERCURY PHOTOSENSITIZED CVD OF a-Si:H FILMS.** The reaction kinetic processes for mercury photosensitized CVD ( $\text{Hg}^*\text{-CVD}$ ) in silane were analyzed using a time-dependent, one-dimensional calculation based on mass-, momentum- and energy-conservation equations, including simplified surface reactions such as radical adsorption and hydrogen elimination from the substrate. A good agreement between the measured and the calculated time-varying concentrations of species provides sufficient validity regarding the present model. It is also shown that the saturation of the  $\text{SiH}_4$  decomposition observed by many authors in closed systems can be explained by the abstraction of  $\text{SiH}_4$  from the surfaces by radicals peculiar to the  $\text{Hg}^*\text{-CVD}$  (e.g.,  $\text{HgH}$ ); gas-phase reactions are significantly influenced by surface reactions when the volume-to-surface ratio becomes small. **094872 DEPENDENCE OF THE PERSISTENT PHOTOCONDUCTIVITY IN DOPING-MODULATED a-Si:H MULTILAYERS ON THE EXPOSURE TEMPERATURE.** We find that the photo-induced excess conductivity (persistent photoconductivity, PPC) in doping-modulated hydrogenated amorphous silicon (a-Si:H) is thermally activated for exposure temperatures above 220 K. However, we find a temperature regime between 80 and 220 K in which the PPC measured at 300 K is independent of excitation temperature. Whether the PPC is excited in the thermally activated regime above 220 K or in the temperature-independent regime, the annealing occurs at 410 K. The pre-exponential factor and the activation energy of PPC are related by the Meyer-Neldel rule independent of the excitation temperature. (Edited author abstract) 13 refs.

**094873 CHARACTERISTICS OF RECOMBINATION PROCESSES IN DOPED HYDRATED AMORPHOUS SILICON FILMS.** The results of measurements of the temperature dependences of the dark conductivity and photoconductivity of a-Si:H films, doped from the gas phase or by implantation of phosphorus or boron ions, as well as the effect of preillumination with white light with different duration on the photoconductivity are presented. A model is proposed for carrier recombination in doped films, taking into account the broadening of the levels of dangling bonds and the difference in the coefficients trapping of electrons and holes on neutral and charged dangling bonds. The dependence of the stationary interband photoconductivity on the equilibrium Fermi level and the appearance of the temperature-induced quenching of the photoconductivity in doped films after preillumination are studied on the basis of this model. (Author abstract) 13 refs.

**094874 EQUILIBRIUM DANGLING BOND DENSITIES IN a-Si:H AND ITS RELATED THIN-FILM ALLOYS.** The equilibrium density of dangling bonds is calculated without resort to kinetic arguments. We find that this density depends on temperature and the position of the Fermi energy within the mobility gap. Comparing our results to experimental data on the defect density in doped and light-soaked a-Si:H and to data on related thin-film alloys we are able to distinguish equilibrium from non-equilibrium defect structures. Our considerations suggest that enhanced carrier densities not only drive the equilibrium towards higher defect densities but also enhance the speed of those kinetic processes that establish equilibrium on the microscopic scale. **094875 ESR AND CONSTANT PHOTOCURRENT STUDIES OF SURFACE AND BULK DEFECTS IN a-Si:H.** Surfaces and bulk defect densities in undoped a-Si:H films on a quartz substrate are estimated from the thickness dependence of the defect density by ESR and constant photocurrent method (CPM). For the first time, the thickness of a defective surface layer in a-Si:H is determined by ESR to be about 200 Å. The decrease in surface spin density by HF etching treatment and the difference in photoconductivities measured by illumination from different sides suggest that the free surface layer is more defective than the interface layer on a quartz substrate. (Author abstract) 7 refs.

**094876 TRANSIENT PHOTOCURRENT STUDY OF THE DANGLING BOND CENTRE IN UNDOPED AMORPHOUS SILICON.** The spectra of all four cross-sections for optical transitions associated with a correlated dangling bond centre in undoped amorphous silicon have been derived by combining transient and modulated photocurrent measurements. Analysis of the spectral shape of these cross-sections yields the energies of transitions between extended band states and the dangling bond centres with single and double occupancy, providing a unique energy placement of the dangling bond states. The results show that the singly and doubly occupied dangling bond states are located about 0.88 and 0.62 eV below the conduction-band edge, respectively, and the effective correlation energy is around 0.26 eV. Lattice relaxation energies are found to be between 0.09 and 0.13 eV. This implies a negligible role for lattice relaxation in the dangling bond transitions. (Author abstract) 39 refs.

**094877 CHARACTERIZATION OF THE STRUCTURE IN HYDROGENATED AMORPHOUS SILICON BY MEANS OF  $^{119}\text{Sn}$  MOSSBAUER SPECTROSCOPY.** The network structure in hydrogenated amorphous silicon (a-Si:H) films including a small amount of tin has been investigated by means of Mossbauer spectroscopy. The quadrupole splitting  $\Delta$  of  $^{119}\text{Sn}$  nuclei in a-Si:H films is very sensitive to the difference in the hydrogen bonding configuration, and is concluded to be a useful parameter for the characterization of the amorphous structure. The relation between  $\Delta$  and the IR spectra shows that the over-constrained region is formed in the a-Si:H network by the SiH group. (Author abstract) 21 refs.

**094878 PRODUCTION OF EXCESS INTERSTITIALS BY PRE-AMORPHISATION.** Single-crystal silicon has been amorphized by bombardment with  $\text{Si}^+$ ,

$\text{Ge}^+$  or  $\text{Sn}^+$  ions. After conventional annealing (900°C, 30 min) some disorder remained. The amount was measured by ion channelling and transmission electron microscopy and compared with the quantity of excess interstitials predicted by the Monte Carlo computer program TRIM. Both the predicted and measured integral disorder fell as the atomic weight of the projectile increased. Because lattice strain also leads to a reduction in ion channelling this had to be taken into account when estimating residual damage from back-scattering analysis. Our results indicate that there are six scattering centers per interstitial. (Author abstract) 10 refs.

**094879 AMPLIFICATION OF PHOTOCONDUCTIVE GAIN WITH SPACE CHARGE DOPING IN MINI MULTILAYERED STRUCTURE.** Optoelectrical properties of a-Si:H(F) multilayers consisting of alternating intrinsic and phosphorus doped layers (mini structure) have been investigated as a function of sublayer thickness by steady state and transient photocurrent measurements. The modulation of the band potential by space charge doping leads to high photoconductivity of the order  $10^{-3}$  S/cm under an illumination of  $10^{14}$  photons/cm<sup>2</sup>s, while maintaining a dark conductivity as low as that of  $10^{-10}$  S/cm. A high photoconductive gain above 10 is obtained for the reverse-biased Schottky diode by controlling the ratio of its thickness and doping level. (Author abstract) 12 refs.

**094882 ANOMALOUS CHANGE OF d.c. CONDUCTIVITY WITH AMBIENT CONDITIONS IN SLOWLY-DEPOSITED SPUTTERED  $\alpha$ -Si AND  $\alpha$ -Si:H.** Electrical d.c. conductivity  $\sigma$  of sputtered  $\alpha$ -Si and weakly-hydrogenated  $\alpha$ -Si:H has been measured between 77 and 400 K, both in dry helium and vacuum ambient. Although the former ambient condition led exactly to the well-known  $\sigma \propto T^{-1/4}$  law, significant deviation from this law has been observed in vacuum at low temperatures. Both behaviours show up reproducibly and interchangeably by varying the ambient conditions. This is believed to arise from the particular microvoid structure of the films studied, depending on which the

ambient condition has a physical influence on the measured d.c. conductivity. This relates to the question about which ambient condition shows up most reliable to measure  $\sigma$  in and what is meant by 'bulk' conductivity. (Author abstract) 12 refs.

**094883 EFFECT OF BOND-ANGLE AND DIHEDRAL-ANGLE DISORDERS ON THE TOP OF THE VALENCE BAND OF AMORPHOUS SILICON.** We have considered the electronic structure of amorphous silicon using a tight-binding method with all first-neighbor couplings in a continuous random network. The effects of bond-angle and dihedral-angle disorders were examined keeping only the nearest-neighbor interactions in the Hamiltonian. The dihedral-angle and bond-angle disorders were found to be important at the valence-band edge and responsible for the observed features near the top of the valence band. We find the same results as J. Singh et al., i.e. that in the top of the valence-band there is a tail of localized states  $\approx 0.5$  eV in width. (Author abstract) 22 refs.

**094893 IDENTIFICATION OF ELECTRON AND**

**HOLE PICOSECOND TRAPPING PROCESSES IN DOPED  $\alpha$ -Si:H.** Using the picosecond pump and probe technique we identify the electron and hole contributions to the photomodulation response in doped  $\alpha$ -Si:H. We have found that electron trapping in doping related defects is about 50 times faster than hole trapping regardless of doping type and concentration, temperature, light exposure or the energy level of the traps. This is an intrinsic property of  $\alpha$ -Si:H which originates from a larger electron hopping rate among localized states in the conduction band-tail due to a larger extent of the electron wave function. (Author abstract) 20 refs.

**094895 HOLE CARRIER DRIFT-MOBILITY MEASUREMENTS IN  $\alpha$ -Si:H, AND THE SHAPE OF THE VALENCE-BAND TAIL.** A detailed study has been performed concerning the temperature and electric-field dependence of hole carrier time-of-flight pulses in amorphous silicon. Various aspects of the experimental behavior are employed in the estimation of the energy distribution of other characteristics of localized states in the films. Over the depth range 0.2 to 0.45 eV, the trap concentration is found to vary more rapidly than the exponential form assumed in earlier studies, and a Gaussian tail is in better agreement with the data. Localized-state capture cross-sections are calculated as  $1.3 \times 10^{-16}$  cm<sup>2</sup>, and are essentially independent of depth over the range studied. Taking the present data in conjunction with the energy distribution of states as determined by other techniques allows an estimation of the mobility of free holes. The value of about  $10 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$  thus obtained is an order of magnitude larger than the previous estimate from time-of-flight measurements, but is comparable to the figures suggested by other transport data. (Author abstract) 18 refs.

**094896 DRIFT MOBILITY IN n- AND p-CONDUCTING  $\alpha$ -Si:H.** The drift mobility of a series of undoped and doped  $\alpha$ -Si:H films has been determined from their steady-state photoconductivity and response time. The drift mobilities at 300 K were  $0.1 \text{ cm}^2 \text{ V}^{-1}$  and  $5 \times 10^{-4} \text{ cm}^2 \text{ V}^{-1}$  for electrons and holes, respectively. The activation energies were 0.13 and 0.27 eV. There is no influence of doping up to a doping level of 1000 ppm of either  $\text{PH}_3$  or  $\text{B}_2\text{H}_6$ . The temperature dependence of the response time reflects changes in the dominant recombination path. At low temperatures tunnelling processes prevail but with increasing temperature direct capture of free carriers by dangling bonds becomes predominant. (Author abstract) 25 refs.

**094897 ATOMIC STRUCTURE OF AMORPHOUS SILICON.** A supercell configuration and the self-consistent pseudopotential method are applied to study the structural properties of amorphous silicon ( $\alpha$ -Si). Starting from a random atomic arrangement in the supercell, a local equilibrium structure is obtained by minimizing the total energy of the system. In the equilibrium, a short

range order is formed. Most atoms are 4-fold coordinated, but also appear 3-fold, and 5-fold coordinated atoms. In addition, 3-membered rings are found. The calculated total energy variations due to volume changes explain the pressure induced phase changes of  $\alpha$ -Si. (Author abstract) 23 refs.

**094899 ESR IN P/I HETEROJUNCTIONS BASED ON  $\alpha$ -Si:H.** Amorphous silicon ( $\alpha$ -Si:H) solar cells have been rapidly coming into practical use. The conversion efficiency of  $\alpha$ -Si:H solar cells has been improved to 11.5% in a small area ( $1 \text{ cm}^2$ ) and 9.3% in a large area ( $100 \text{ cm}^2$ ). Electron spin resonance (ESR) has provided useful information concerning deep levels in undoped hydrogenated amorphous silicon. The authors report the first ESR study of P/I structures which closely simulate photovoltaic devices. The influence of carbon content in the p-layer and the illumination time on the spin density ( $N_s$ ), g-value, and peak to peak linewidth ( $\Delta H_{pp}$ ) was investigated. 6 refs.

**094901 INVESTIGATION OF UV-UV-IR SPECTRA FOR AMORPHOUS SEMICONDUCTOR SUPERLATTICES.** We have successfully made amorphous semiconductor superlattices of  $\alpha$ -Si:H/ $\alpha$ -Si $_{1-x}$ C $_x$ H films consisting of 28-102 periods of 10-200 Angstrom thick  $\alpha$ -Si:H and 60 Angstrom  $\alpha$ -Si $_{1-x}$ C $_x$ H by periodic alternating the plasma gas mixture in single reaction chamber of plasma deposition system. The results of TEM and XPS show smooth and sharp boundaries between the layers. The vibration modes of (Si-H)N stretchbonds and extra hydrogen bonded at the interface have been discovered by analysing the fine structure of the (Si-H) stretch mode in the wavenumber of  $2400\text{-}1800 \text{ cm}^{-1}$ . The results of investigation of UV-UV spectra indicate that the shift of optical energy gap in  $\alpha$ -Si:H/ $\alpha$ -Si $_{1-x}$ C $_x$ H superlattices is induced by quantum well effect. (Author abstract) 16 refs. In Chinese.

**094902 EFFECT OF INTERRUPTING FILM GROWTH ON THE PROPERTIES OF  $\alpha$ -Si:H.** This paper compares photoluminescence, optical absorption, H-evolution, and infrared vibrational spectra of glow-discharge deposited hydrogenated amorphous silicon,

a-Si:H, prepared in three different ways: continuous deposition and deposition interrupted hundreds of times either by a shutter or by shutting off the plasma power. The latter yields an excess hydrogen content, a blue shift of the optical gap, and a decrease in the photoluminescence intensity. The results are related to the initial non-equilibrium plasma chemistry. (Author abstract) 11 refs

**094903 DENSITY OF STATES IN NONCRYSTALLINE SOLIDS.** The paper considers the energies of all the electrons in a semiconductor and all the possible energies electrons can attain after they have been given some additional energy, for instance, by absorption of sunlight or by heating the material. The problem is difficult because there are about  $10^{24}$  electrons in  $1 \text{ cm}^3$  of amorphous (or crystalline) silicon. That is as many electrons as there are sand grains in one million cubic yards of sand. The investigative method used by the author is to deduce the electronic states from chemical arguments and a few experiments. 40 refs.

**094904 GEMINATE RECOMBINATION AND INJECTION CURRENT: DIAGNOSTICS FOR EXTENDED STATE MOBILITY.** In this paper the author raises the question, Is the extended state mobility in a-Si:H low ( $10 \text{ cm}^2/\text{V}\cdot\text{s}$ ) or high ( $> 200 \text{ cm}^2/\text{V}\cdot\text{s}$ )? This will be treated by examining two seemingly independent phenomena: (1) geminate recombination and (2) injection currents. The former refers to a primary photo-excitation process leading to a production of free carriers. This process involves the probability of escape of an excited pair from each other. Among the various factors governing this primary yield is the extended state mobility which determines how far apart the pair will be when they become thermalized. If the mobility is low, the mean free path is small and they diffuse apart during thermalization. On the other hand, if the mobility is high, the mean free path is large and they move apart ballistically in the range of the Coulomb interaction. In the former case, the separation is generally small and the yield would be expected to be small. In the latter case, the separation would be large and the yield approaches unity. 21 refs.

**094906 RECOMBINATION AT DANGLING BONDS AND BAND TAILS: TEMPERATURE DEPENDENCE OF PHOTOCONDUCTIVITY IN HYDROGENATED AMORPHOUS SILICON.** The theory of recombination of dangling bonds and band tails is

developed. The statistics for correlated defects are included and the Shockley-Read formalism is extended to asymmetric exponential distributions of tail states. Parametrical representations of the photoconductivity and the charge densities are obtained. A comparison of the results explains the thermal quenching of the photoconductivity experimentally observed. At low temperatures, the photoconductivity is determined by the balance between the two band-tail charge densities. At higher temperatures, one band-tail density becomes negligible compared with the dangling-bond charge density and the photoconductivity is controlled by the latter. Finally, the variations in photoconductivity with the density-of-states parameters are discussed. (Edited author abstract) 28 refs.

**094907 DEPENDENCE OF HYDROGEN DIFFUSION ON GROWTH CONDITIONS IN HYDROGENATED AMORPHOUS SILICON.** The dependence of the hydrogen diffusion coefficient on the material growth conditions in doped hydrogenated amorphous silicon has been measured, using secondary-ion mass spectrometry. A greatly enhanced diffusion was found in material with a columnar microstructure because of the preferential motion of hydrogen along the columns. Increasing the deposition temperature in noncolumnar material results in a higher diffusion coefficient and a lower hydrogen concentration. No significant change in the diffusion was found with different n-type dopants. (Author abstract) 13 refs.

**094911 PREPARATION AND APPLICATIONS OF**

**AMORPHOUS SILICON.** This chapter is concerned with the preparation, properties, and possible applications of amorphous silicon (a-Si) prepared by the glow-discharge (gd) decomposition of silane. It was discovered that a-Si prepared by the gd technique possesses a low density of states in the mobility gap, probably the most important single factor in its applied potential. A direct result of this has been the development of the a-Si field-effect transistor (FET) which could find applications in large-area addressable displays, in addressable image-sensing arrays, and in logic circuits. Various additional developments and discoveries are reported and discussed. 33 refs.

**094913 UTILISATION DU SILICIUM AMORPHE HYDROGENE DANS LA REALISATION DE MIROIRS POUR LASERS HAUTE ENERGIE A  $\lambda = 10.6 \mu\text{m}$ .** [Utilization of Hydrogenated Amorphous Silicon to Realize Mirrors for High-Energy Lasers at  $\lambda = 10.6 \mu\text{m}$ .] Hydrogenated amorphous silicon thin films are hard, with low porosity and have a high refractive index. Owing to its mechanical and chemical properties, this material is attractive to be used as a thin protective film for  $\text{CO}_2$  laser mirror coatings. Unfortunately the low absorption at  $10.6 \mu\text{m}$  is too high for quarter-wave layer at that wavelength in enhanced metallic coatings. Nevertheless, when associated with a classical transparent but softer high index material such as  $\text{ZnS}$  or  $\text{ZnSe}$ , hydrogenated amorphous silicon can be used in order to design the last composite high index quarter-wave layer. Theoretical calculations predict an optimum reflectance for a fixed a-Si:H thickness. The silicon is thin enough to obtain a high reflectivity coating but thick enough to provide a good chemical and mechanical protection. (Edited author abstract) 10 refs. In French.

**094914 RADIATION INDUCED CRYSTALLIZATION OF AMORPHOUS Si:H ALLOY.** The microcrystalline phase of hydrogenated silicon ( $\mu\text{c-Si:H}$ ) has recently drawn interest as a new phase material for applications in thin film solar cells. Two stage radiation-enhanced nucleation has been observed in thin films of hydrogenated amorphous silicon. A microcrystalline-amorphous ( $\mu\text{c-a}$ ) mixed phase can be produced at room temperature from RF glow discharge amorphous thin films by using neutron irradiation with a dose of  $2 \times 10^{16}$  neutrons/ $\text{cm}^2$ . The subsequent annealing at  $150^\circ\text{C}$  using a built-in heating stage in a transmission electron microscope (TEM) can produce a high volume fraction of  $\mu\text{c}$  phase with an average grain size of 150 Angstroms. According to the in situ annealing data, the neutron irradiated film exhibits a nucleation controlled phase transformation. (Author abstract) 23 refs.

**094915** <sup>29</sup>Si DYNAMIC NUCLEAR POLARIZATION OF DEHYDROGENATED AMORPHOUS SILICON. <sup>29</sup>Si NMR spectra were obtained on a dehydrogenated amorphous silicon sample by means of dynamic nuclear polarization (DNP). The dependence of the DNP enhancement factor, which peaked at about 40, upon the microwave frequency offset ( $\omega - \omega_0$ ) from the electron spin Larmor frequency is essentially antisymmetric about  $\omega - \omega_0 = 0$ , which corresponds to a  $g$  value of 2.0059. This observation shows that the paramagnetic centers are fixed, immobile on the time scale of electron spin Larmor precession, requiring a reexamination of recently advanced models of the paramagnetic defects. Prospects for the application of DNP in the study of amorphous silicon materials are discussed. (Author abstract) 20 refs.

**094916** THERMAL-EQUILIBRIUM PROCESSES AND ELECTRONIC TRANSPORT IN UNDOPED HYDROGENATED AMORPHOUS SILICON. The temperature and time dependence of the d.c. conductivity of undoped hydrogenated amorphous silicon is presented. Measurements of the electronic transport are reported, with particular emphasis on the effects of annealing and cooling the samples. Two regimes of behaviour are observed. When samples are rapidly cooled from 200°C below a temperature  $T_E$  approximately 145°C a non-equilibrium dark conductivity, higher than that corresponding to slow cooling, is observed. The electronic and atomic structure then slowly relax and the time dependence of the excess conductivity is well described by a stretched exponential function. The second regime above  $T_E$  corresponds to a relaxation time short compared to experimental times and the conductivity is independent of which order the annealing temperature is chosen. Thus the thermal equilibrium processes observed in undoped samples are qualitatively very similar to those observed in doped samples as recently reported in the literature. (Author abstract) 15 refs.

**094917** DRIFT MOBILITY UNDER SINGLE AND DOUBLE INJECTION IN HYDROGENATED AMORPHOUS SILICON. To test the effect of charged defect centers in a-Si:H we have performed drift-mobility measurements using a small-voltage-step technique in p-i-n and M-i-n samples already under strong forward bias. These measurements have been made as a function of forward bias and temperature. The drift mobility under double injection was of the order of one decade larger than that under single injection. The respective activation energies were approximately 0.13 and 0.17 eV while the activation energies for the forward-bias currents were approximately 0.45 and 0.64 eV. We suggest that the differences in drift mobility are a result of an increase in the extended-state mobility arising from neutralization of the charge defects under double injection, which is not possible under single injection. (Author abstract) 7 refs.

**094918** ELECTRON DIFFRACTION STUDY OF THE STRUCTURE OF BORON- AND PHOSPHORUS-DOPED HYDROGENATED AMORPHOUS SILICON. The effect of gas-phase doping with boron and phosphorus on the structure of glow-discharge amorphous hydrogenated silicon has been studied by means of energy-filtered electron diffraction. The reduced density function was calculated and the network was found to contract upon doping. At levels of less than 20 at% neither boron nor phosphorus segregated from the network. At high phosphorus doping levels an amorphous chemically ordered structure corresponding to  $Si_2P$  was formed. At high boron doping levels, evidence for the presence of boron icosahedra was obtained. (Author abstract) 12 refs.

**094919** DENSITY OF MID-GAP STATES FOR UNDOPED a-Si<sub>1-x</sub>Ge<sub>x</sub>H AND a-Si:H DETERMINED BY STEADY-STATE HETEROJUNCTION-MONITORED CAPACITANCE METHOD. A simple technique has been described for determining the density of mid-gap states of highly resistive amorphous semiconductors, using amorphous/crystalline heterojunction structures. The technique has been tested and applied on undoped hydrogenated amorphous silicon films and silicon-germanium alloy films, covering the optical gap range of 1.30 to 1.76 eV. Those densities obtained from this technique have been found to be densities of singly-occupied dangling bonds. (Author abstract) 8 refs.

Matsuura, Hideharu (Electrotechnical Lab, Tsukuba, Jpn). *Jpn J Appl Phys Part 2* v 27 n 4 Apr 1988 p 513-515.

**094920** DENSITY-OF-STATE DISTRIBUTION FOR UNDOPED a-Si:H AND a-Si<sub>1-x</sub>Ge<sub>x</sub>H DETERMINED BY TRANSIENT HETEROJUNCTION-MONITORED CAPACITANCE METHOD. A novel technique has been proposed for determining the density-of-state (DOS) distribution in the mobile highly resistive amorphous semiconductors, using amorphous/crystalline heterojunction structures. This technique has been tested and applied on undoped hydrogenated amorphous silicon (a-Si:H) films and silicon-germanium alloy Ge<sub>x</sub>H films, covering the optical gap range ( $E_g$ ) of 1.55 eV to 1.76 eV. For undoped a-Si:H ( $E_g = 1.76$  eV), the mid-gap DOS distribution has been located at 0.85 eV below the conduction band mobility edge, with a  $5.6 \times 10^{15} \text{ cm}^{-3} \text{ eV}^{-1}$ . (Author abstract) 10 refs.

**094921** EVIDENCE FOR THERMAL DEFECT CREATION IN AMORPHOUS SILICON. Comparison of contactless time-resolved photoconductivity experiments at 200°C and at 23°C yields evidence for a thermal defect creation in the network of hydrogenated amorphous silicon (a-Si:H). In undoped a-Si:H these defects act mainly as hole traps and lead to an increased effective electron lifetime. In p- and n-type samples the effective majority carrier lifetime is reduced at higher temperatures due to the thermal generation of recombinative states. (Author abstract) 11 refs.

Werner, A. (Hahn Meitner Inst, Berlin, West Ger); Kunst, M. *Solid State Commun* v 65 n 12 Mar 1988 p 1501-1503.

**094922** PROPERTIES OF AMORPHOUS Si:H FILMS PREPARED BY DUAL ION BEAM SPUTTERING. The Ion Beam Sputtering (IBS) and the Dual Ion Beam Sputtering (DIBS) allow independent control of the deposition kinetics and the hydrogenation of hydrogenated amorphous silicon (a-Si:H) films. This makes it possible to investigate the correlations between the disorder in the amorphous matrix and the optical parameters, such as optical gap and Urbach energy. Data were taken for samples grown at different substrate temperatures, having different hydrogen content, or presenting damage induced by argon bombardment. In addition, an experimental evaluation of the shift in optical gap due to the alloying with H was carried out and gave  $6.63 \times 10^{-3} \text{ eV/at\%}$ . (Author abstract) 10 refs.

**094923** LOW PRESSURE CHEMICAL VAPOUR DEPOSITION AMORPHOUS SILICON BEHAVIOUR UNDER ANNEALING. Four types of amorphous silicon materials were grown in a low pressure chemical vapour deposition (LPCVD) system and their differences in colour, adherence, and smoothness, as well as crystallinity of the derived materials were investigated as a function of annealing temperature. Experimental results indicate that amorphous silicon growth can occur either

through a heterogeneous mechanism on the substrate surface or through homogeneous nucleation in the vapour phase. In general, surface-grown amorphous silicon renders high quality polysilicon after annealing. This is not the case for amorphous silicon nucleated in the vapour phase, which produces poor quality polysilicon under similar temperature conditions. (Author abstract) 17 refs.

**094924** PICOSECOND PHOTOMODULATION STUDIES OF CARRIER TRAPPING IN a-Si:H. Subnanosecond trapping in gap states of photogenerated carriers in doped, compensated and undoped a-Si:H, and a-Si:H/a-Si<sub>3</sub>N<sub>4</sub>/H multilayer structures, was studied by the picosecond pump and probe technique. In undoped a-Si:H the photoexcited carriers are trapped in band-tail states and in compensated a-Si:H in impurities introduced by doping. In singly doped a-Si:H the photoexcited majority carriers are trapped in impurities while the minority carriers are trapped in charged dangling bonds introduced by doping. In a-Si:H/a-Si<sub>3</sub>N<sub>4</sub>/H superlattices photocarriers are trapped in interface related defects. The transport dynamics of the trapping process is in all cases dispersive. (Author abstract) 28 refs.

Vardeny, Z. (Brown Univ, Providence, RI, USA); Taue, J. *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 339-348.

**094925** PHOTOLUMINESCENCE STUDIES OF BAND-TAIL STATES IN a-Si:H. There is general agreement that the 1.4 eV emission band in a-Si:H arises from recombination of carriers trapped within the valence and conduction-band tails. Time-resolved measurements of this emission suggest that at low temperatures the carriers thermalize within the tails by direct hopping to lower-energy states, and that only one species is moving. The high transfer rates imply that these states may not be as localized as previously thought. During thermalization the recombination is dominated by radiative processes which are reaction rather than diffusion limited. Non-radiative processes are found to be operative on very short (ps) and long ( $\mu$ s) time scales, but do not appear important during this regime of rapid thermalization. (Edited author abstract) 24 refs.

**094926** RECOMBINATION IN a-Si:H BASED MATERIALS: EVIDENCE FOR TWO SLOW RADIATIVE PROCESSES. New time resolved photoluminescence measurements show that two radiative processes contribute to the approx. 1.3 eV emission band seen in a-Si:H. These processes are distinguished by their different lifetimes. Similar lifetime distributions are seen in a-Si<sub>3</sub>N<sub>4</sub>/H alloys and also in a-Si:H based multilayers. Time resolved electroluminescence and photoconductivity also have similar lifetime distributions. The temperature and excitation intensity dependence of the lifetime distributions provide evidence for saturation effects. Together with spectral measurements, these data reveal a range of radiative slow processes below approx. 20  $\mu$ s, and a predominantly nonradiative channel with a lifetime of about 8  $\mu$ s. (Edited author abstract) 11 refs.

**094927** THERMAL AND OPTICAL QUENCHING OF THE PHOTOCONDUCTIVITY IN a-Si:H FILMS. It is shown that there are major inconsistencies in the current interpretations of optical and thermal quenching of the photoconductivity in a-Si:H. The quenching phenomena are studied in differently doped

samples and in the accumulation layer of a field effect transistor where the occupancy of the centers can be controlled by the gate potential. It is found that optical and thermal quenching arise from different excitation processes: Thermal quenching, which is only observed in samples where the Fermi level is close to midgap, is attributed to the temperature enhanced transfer of holes to D<sup>-</sup> states; optical quenching is suggested to arise in all kinds of samples from the excitation of electrons from D<sup>-</sup> states, and its temperature dependence is shown to originate from the competition of direct capture of electrons in neutral dangling bonds with tunneling transitions of band tail electrons. (Edited author abstract) 19 refs.

**094928 RECOMBINATION AND THE STANDARD MODEL IN AMORPHOUS HYDROGENATED SILICON (a-Si:H): AN ESSAY.** Non-radiative photocarrier recombination in amorphous hydrogenated silicon (a-Si:H) is reviewed. Emphasis is given to undoped material in the room temperature regime and to the effects upon photocarrier processes of the D center observed in electron spin resonance. The measurements include electron spin resonance, transient and steady-state photoconductivity, spin-dependent photoconductivity, and surface photovoltage. Three issues are addressed: (i) Is the electron recombination process due to tunneling or to free-to-bound transitions? (ii) Is there an important electron trap, and is the D<sup>0</sup> such a trap? (iii) Is electron capture by the D<sup>0</sup> center and hole capture by the D<sup>-</sup> the dominant recombination channel? (Edited author abstract) 21 refs.

**094929 OPTICAL AND PHOTOELECTRICAL PROPERTIES OF a-Si:H IMPLANTED BY Mg IONS.** The authors studied the photoluminescence and the spectral dependence of photoconductivity of a-Si:H layers with various concentrations of implanted Mg ions after subsequent anneal at 350 and 500°C. The aim was to clarify the possibility of preparation of weakly doped a-Si:H layers of p-type with stable properties. 8 refs.

**094930 DETERMINATION OF THE ELECTRONIC DENSITY OF STATES OF N-TYPE HYDROGENATED AMORPHOUS SILICON FROM TRANSIENT SWEEP-OUT EXPERIMENTS.** We analyze the forward-bias transient response of hydrogenated amorphous silicon (a-Si:H)  $i/n/i$  structures in terms of the space-charge and emission limited currents. It is shown that the initial space-charge limited current in the thicker  $i$  layer gives way at later times to an emission-limited current from the  $n$  layer. The temporal dependence of the current depends upon the density of states and the position of the Fermi level in the  $n$  layer as well as upon the applied voltage and characteristics of the  $i$  layer. Comparison with the experimental data suggests that the electronic density of states in  $n$ -type a-Si:H has a peak within 0.3 eV below the conduction-band mobility edge. (Author abstract) 4 refs.

Silver, Marvin (Univ of North Carolina, Chapel Hill, NC, USA); Adler, David; Branz, Howard M. *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 401-406.

**094931 ELECTRON CORRELATION ENERGIES IN HYDROGENATED AMORPHOUS SILICON.** The existence of defects with a negative correlation energy in amorphous silicon is still a question of controversy. Basically, two classes of defect models exist for this material. The first model states that the bulk of the

available experimental data can be explained by considering three major defect states (valence band tail states, dangling bonds, and conduction band tail states), all of which have positive-U character. The second class of models agrees with the existence of some positive-U defect states but, in addition, postulates the existence of some positive-U defect states, but, in addition, postulates the existence of an even larger density of negative-U defects, especially dangling bonds. The authors report some new experimental results which might help resolve part of the discrepancy between these two models. 23 refs.

**094932 DEFECTS IN a-Si:H.** Defects in a-Si:H play an important role in its electronic properties because they give rise to gap states acting as either trapping centers or recombination centers. However, knowledge of them is still lacking. The authors discuss the nature of some defects in a-Si: H, particularly deep gap states and light-induced ESR (LESR) centers exhibiting ESR of  $g$ -values either  $g=2.004$  or  $g=2.013$  in undoped a-Si:H as well as similar centers in doped a-Si:H. The authors present evidence that some of the deep gap states are correlated with nitrogen impurities and discuss their role in photoinduced phenomena as well as their microscopic nature. The authors discuss the nature of LESR centers in undoped a-Si:H as well as those of similar centers and other defects in doped a-Si:H in the light of our recent ESR and ODMR measurements. 37 refs.

**094933 OPTICAL ABSORPTION EDGE OF HYDROGENATED AMORPHOUS SILICON.** In earlier work the authors reported the shape of the absorption edge of a-Si:H using photoacoustic spectroscopy (PAS), from which the slope of the valence-band tail as well as the defect-state profile was determined. In this paper, a recent PAS technique is described for determining the optical absorption spectrum of a-Si:H in the temperature range of 10 K < T < 300 K. The optical absorption edge ( $1 < \alpha < 10^3 \text{ cm}^{-1}$ ) of a-Si:H is presented as a function of the measurement temperature, substrate temperature and post-annealing temperature. On the basis of the results, it is demonstrated that not only the disorder, thermal (dynamical) as well as structural (frozen-in), but also the bonded-hydrogen content determine the optical bandgap of a-Si:H. 15 refs.

**094934 PREPARATION OF a-Si AND ITS RELATED MATERIALS BY HYDROGEN RADICAL ENHANCED CVD.** A novel method of preparing a-Si and its related materials from fluorides, i.e., Hydrogen Radical Enhanced CVD (HRCVD), is proposed. This method is based on control over the chemistry both in the gas phase and in the growing surface with the aid of hydrogen atoms. The high quality of the films is achieved due to a reduction in the density of states both in the midgap and in the valence band tail, resulting in the high photoelectric properties and the nondispersive hole transport, while the network structure in the Si films is controlled intentionally from the amorphous form to the crystalline form under the epitaxial growth by the new technique. (Author abstract) 48 refs.

**094935 APPLICATION OF IN SITU ELLIPSO-**

**TRY TO THE GROWTH OF HYDROGENATED AMORPHOUS SILICON.** The physics of hydrogenated amorphous silicon (a-Si:H) has been studied for a number of years. The knowledge of the fundamental growth mechanisms continues to expand, however, through more detailed measurements of sample microstructure and its connection with plasma processing. In situ ellipsometry is one such measurement which the authors believe holds considerable promise in this regard. The paper provides a review of the current status of the interpretation of ellipsometry measurements of thin film semiconductors. This background material is presented so that the reader will recognize the novel capabilities of in situ ellipsometry for the study of the microstructural evolution of a-Si:H. The paper covers applications of the in situ technique to investigations of (1) the nucleation and interface properties of a-Si:H deposited under different conditions and (2) the effects of N<sub>2</sub> plasma exposure on the a-Si:H surface. 21 refs.

**094936 DENSITY OF GAP STATES IN UNDOPED AND DOPED AMORPHOUS HYDROGENATED SILICON OBTAINED BY OPTICAL SPECTROSCOPY.** Density of states (DOS) in the mobility gap of amorphous hydrogenated silicon (a-Si:H) is important since it influences the electrical and photoelectrical properties of this material. The silicon dangling bond is a basic deep defect in a-Si:H, the energy position of which is a function of its electron occupation. This defect has been studied by electron spin resonance, luminescence, optical absorption, photoconductivity, conductivity and capacitance techniques, but there exists still disagreement about the position of the silicon dangling bond within the gap. The authors present an approach based on photoconductivity technique used for measuring small optical absorption in subgap region. Measurement of the subgap absorption spectra by means of the constant photocurrent method (CPM), together with the measurement of the photothermopower and the mobility gap value, have enabled the authors to determine the density and position of the dangling bond in a different charge state within the mobility gap for undoped and doped a-Si:H. A new model for the density of gap states in doped a-Si:H is presented. 27 refs.

**094937 STRUCTURAL CHARACTERIZATION OF AMORPHOUS SILICON AND GERMANIUM.** We have derived a simple relationship between the measured TO-phonon frequency and the square of the TO-phonon Raman linewidth. The minimum strain energy calculated from the minimum  $\Delta\theta$  prior to crystallization compares favorably with the enthalpy of crystallization, being 15 KJ/mole for a-Si and 9.4 KJ/mole for a-Ge. The variation of  $\Delta\theta$  with T<sub>a</sub> may be fitted to an activated process resulting in an energy barrier of approximately 0.19 eV and 0.18 eV for a-Si and a-Ge, respectively. We have also derived an expression allowing the determination of  $\Delta\theta$  from optical absorption, thereby opening the door for many investigators regarding a quantitative measure of  $\Delta\theta$ . Since  $\Delta\theta$  affects the distance between the second nearest neighbors, the minimum hydrogen content for strain relieving is 6%, although it is more probable that 12% is required if two hydrogen atoms are bonded to two adjacent atoms. (Author abstract) 31 refs.

Tsu, Raphael (Solar Energy Research Inst, Golden, CO, USA). *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 479-488.

**094938 RESONANT TUNNELING THROUGH QUANTIZED STATES IN a-Si:H.** Ultra-thin multilayer structures consisting of amorphous silicon (a-Si:H) and

silicon-based materials such as amorphous silicon nitride ( $a\text{-Si}_{1-x}\text{N}_x\text{:H}$ ), silicon carbide ( $a\text{-Si}_{1-x}\text{C}_x\text{:H}$ ), or silicon germanium ( $a\text{-Si}_{1-x}\text{Ge}_x\text{:H}$ ) have been extensively studied. The layer thickness can be controlled on an atomic scale and hence the optical and electrical properties have been interpreted by assuming the quantized states in the conduction and valence bands of the potential well layers, as in the case of crystalline semiconductor superlattices. However, there has been a current question whether or not the quantum size effect is really existing in ultra-thin amorphous semiconductor multilayers. We report on the resonant tunneling phenomena through  $a\text{-Si}_3\text{N}_4\text{:H}/a\text{-Si:H}/a\text{-Si}_3\text{N}_4\text{:H}$  double barrier structures. This is direct evidence of the quantization effect in an amorphous silicon well layer sandwiched with stoichiometric silicon nitride barriers. 10 refs.

**094939 PERSISTENT PHOTOCONDUCTIVITY IN AMORPHOUS SILICON ALLOYS.** We have reviewed the present status of the enhanced conductivity observed in various  $a\text{-Si:H}$  structures upon a brief light exposure. It is pointed out that this effect is larger and persists longer in the doping modulated multilayers and compensated films of  $a\text{-Si:H}$  as compared with doped and undoped single layers and  $a\text{-Si:H}/a\text{-SiN}_x\text{:H}$  multilayers. The large effect in doping modulated and compensated films can be explained by assuming the presence of special centers with barriers, which are either already present or are created by light exposure in the upper half of the gap and are related to the presence of P and B, or B alone. 20 refs.

**094940 THERMAL EQUILIBRATION MODEL FOR PERSISTENT PHOTOCONDUCTIVITY IN DOPING MODULATED AMORPHOUS SILICON.** The persistent photoconductivity effect in doping modulated amorphous silicon is compared to the light-induced conductivity changes in compensated amorphous silicon. The recent proposal that the defect structure of doped amorphous silicon is in metastable thermal equilibrium is able to account for the metastable excess conductivity in both systems, and for the several orders of magnitude difference in exposure times needed. 19 refs.

**094941 BAND EDGE ALIGNMENT AND QUANTUM SIZE EFFECTS IN HYDROGENATED AMORPHOUS SILICON GERMANIUM SUPERLATTICE STRUCTURES.** We deduce conduction and valence band alignments in hydrogenated amorphous silicon/germanium superlattices from the layer thickness dependence of coplanar conductivity and thermoelectric power, Schottky barrier height, and optical absorption. We find that the amorphous germanium conduction band edge lies approx. 0.5 eV below and the valence band edge approx. 0.15 eV above the corresponding amorphous silicon edge. (Author abstract) 12 refs.

**094942 JUNCTION CAPACITANCE STUDIES OF HYDROGENATED AMORPHOUS SILICON DOPING SUPERLATTICE FILMS.** We report junction capacitance measurements of amorphous silicon nini doping superlattice samples. By analyzing capacitance-voltage measurements at a series of temperatures we have deduced the densities of both shallow and deep states in each of the constituent layers. We conclude that the

deep defect density in the intrinsic regions is nearly equal to that in the n-type regions and thus much greater than that in bulk intrinsic material. These measurements disclose the existence of distinct interface states at the n-i and i-n boundaries with energies that strongly suggest that they are dangling bond defects. Both results have implications regarding mechanisms of dangling bond formation in amorphous silicon. (Edited author abstract) 12 refs.

**094943 EFFECTS OF BAND BENDING ON THE OPTICAL, ELECTRICAL AND PHOTOELECTRONIC PROPERTIES OF  $a\text{-Si:H}$  THIN FILMS IN SURFACE CELL STRUCTURES.** We have studied the optical, electrical and photoelectronic properties of  $a\text{-Si:H}$  thin films in surface cell structures and have concluded that band bending at dry nitrogen  $a\text{-Si:H}$  surfaces and oxide glass  $a\text{-Si:H}$  interfaces makes many of these properties appear to be thickness dependent. We show that the  $a\text{-Si:H}$  alloys are homogeneous, and that the thickness dependence can be deduced from a model that includes an upward band bending, i.e., depletion regions, at both thin film surfaces. (Edited author abstract) 20 refs.

**094944 HYDROGEN MOTION AND THE STAEBLER-WRONSKI EFFECT IN AMORPHOUS SILICON.** In 1977 Staebler and Wronski discovered that prolonged illumination could induce reversible changes in the photoconductivity and dark conductivity of hydrogenated amorphous silicon ( $a\text{-Si:H}$ ). Subsequently, similar reversible changes have been observed in the photoluminescence, electron spin density, photovoltaic parameters, and density of gap states in  $a\text{-Si:H}$ . We describe a model for the Staebler-Wronski effect that is based on the assumption that hydrogen is induced to move by the recombination or trapping of carriers and that local bond reconstruction then creates a metastable state. 42 refs.

**094945 DANGLING BONDS AND METASTABILITY IN SEMICONDUCTORS.** All semiconductors have dangling bonds. In crystals they are found on the surface, in grain boundaries, in dislocations, in point defects, near impurities and in vacancies. In amorphous semiconductors, there is a much greater opportunity to form dangling bonds. The author reviews various major observations of metastability in  $a\text{-Si:H}$ , summarizes the main models to be tested, shows that the breaking of weak bonds model is compatible with the charge redistribution model, and presents a perspective on what remains to be done. 32 refs.

Pankove, Jacques I. (Solar Energy Research Inst, Golden, CO, USA). *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 625-633.

**094946 RECOMBINATION-ENHANCED DEFECT FORMATION AND ANNEALING IN  $a\text{-Si:H}$ .** Despite efforts to elucidate the light-induced (or current-induced) instability in  $a\text{-Si:H}$ , one approach has been largely neglected. This approach is the exploitation of analogies between the formation and annealing of metastable defects (MSDs) in  $a\text{-Si:H}$  and the recombination-induced defect reactions in crystalline semiconductors. Defect reactions are any bond rearrangements around a defect, including the motion or creation of a defect. Recent efforts using this approach have (1) produced a conclusion that the light-induced effects in  $a\text{-Si:H}$  are probably of extrinsic origin, in disagreement with current intrinsic models; and (2) shown that a class of physical processes has been overlooked in kinetic analyses of MSD densities. This paper summarizes this approach and its results to date. 17 refs.

Redfield, David (Stanford Univ, Stanford, CA, USA). *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 635-640.

**094947 COMPOSITION AND THERMAL STABILITY OF GLOW-DISCHARGE  $a\text{-Si:C:H}$  AND  $a\text{-Si:N:H}$  ALLOYS.** Reported are results of a broad-scaled investigation of  $a\text{-Si:C:H}$  and  $a\text{-Si:N:H}$  films prepared at laboratories from a wide range of different gases. We characterize the composition of such films with respect to the gas mixture used, employing Auger electron spectroscopy (AES), electron probe microanalysis (EPMA), infrared (IR) absorption and gas effusion experiments. The latter two techniques are applied as a sensitive tool for structural effects in the amorphous material. Gas effusion experiments are also used to elucidate the mechanisms of thermal decomposition of the amorphous films with consequences both for the choice of optimum deposition conditions and for high-temperature applications of the amorphous alloys. The optical band-gap is related to the compositional and structural film properties. 25 refs.

**094948 INVESTIGATION OF THE ELECTRONIC STRUCTURE OF AMORPHOUS SILICON BASED ON STUDIES OF THE AMORPHOUS-TO-CRYSTALLINE TRANSITION.** We discuss features in the electronic density of states (EDOS) of amorphous silicon ( $a\text{-Si}$ ) based on studies of the velocity of the conversion of  $a\text{-Si}$  to crystalline ( $c\text{-Si}$ ) silicon. The discussion adopts a model where charged dangling bonds in the  $a\text{-Si}$  matrix diffuse to the  $a\text{-c}$  interface where they allow conversion of atoms from  $a\text{-to-c}$  configurations. Features in the EDOS are identified and placed in the energy pseudogap. (Edited author abstract) 22 refs.

**094949 STATISTICAL SHIFT OF THE FERMI ENERGY AND THE PREFACTOR OF THE DC CONDUCTIVITY IN  $a\text{-Si:H}$ .** We show that recent models of the density of states distribution lead to large values for the statistical shift of the Fermi level. These agree with transport models which consider transport in extended states only if the rather high prefactor  $\sigma_0 = 2000 \Omega^{-1} \text{cm}^{-1}$  for the dc conductivity is assumed. This is in contradiction to the values proposed recently by Mott and by Fenz et. al. (Edited author abstract) 31 refs.

Overhof, Harald (Univ of Paderborn, Paderborn, West Ger). *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 713-722.

**094950 OPTICAL DEGRADATION OF  $a\text{-Si:H}$  FILMS WITH DIFFERENT MORPHOLOGY.** The optical degradation (Staebler-Wronski (SW) effect) of  $a\text{-Si:H}$  films prepared by plasma CVD has been studied in connection with the morphological inhomogeneity of the films. The relative degradation rate of cubic photoconductivity  $\alpha$  widely varied with deposition substrate temperature  $T_s$  and had its maximum at  $T_s = 200$  to approx.  $250^\circ\text{C}$ . In the films of both the lower and higher  $T_s$ ,  $\alpha$  decreased due to the increase of stable dangling bonds in the former and the decrease of weak bonds in the latter. The SW effect was hardly observed in  $\mu\text{-Si:H}$  deposited from highly diluted silane with hydrogen. (Author abstract) 14 refs.

**094951 THERMAL CONDUCTIVITY OF AMORPHOUS Si AT LOW TEMPERATURES.** Measurements of thermal conductivity of amorphous Si films from 2 to 50 K are presented. The qualitative and quantitative behavior is similar to thermal conductivity of other amorphous dielectrics. The temperature range of the plateau of  $\gamma(T)$  correlates with the maximum  $T_m = 30$  K of the function  $c/T^3(T)$ . An analysis of the effective free path of phonons in dependence on the reduced temperature  $T/\theta_D$  results in a remarkable coincidence for amorphous As, Se, Si, Ge, and  $\text{SiO}_2$ ,  $\text{GeO}_2$  in the plateau range. This fact leads to a restriction of hypotheses for explanation of the plateau of thermal conductivity at amorphous materials. (Author abstract). 26 Refs.

**094952 ION-BEAM-INDUCED EPITAXIAL CRYSTALLISATION (IBEC) OF AMORPHOUS SILICON LAYERS PRODUCED BY CHEMICAL VAPOUR DEPOSITION.** Amorphous silicon layers deposited by chemical vapor deposition on monocrystalline silicon substrates were epitaxially recrystallized by ion beam induced epitaxial crystallization at 400°C after preamorphization of the transition region layer/substrate. In this manner, a layer with a thickness of 400 nm was recrystallized by implanting silicon ions at 330 keV with a dose of about  $1 \times 10^{17} \text{ cm}^{-2}$ . (Author abstract). 6 Refs.

Skorupa, W. (Acad of Sciences of the GDR, Dresden, East Ger); Voelskow, M.; Matthai, J.; Knothe, P. *Electron Lett* v 24 n 14 Jul 7 1988 p 875-876.

**094953 LACK OF CHEMICAL INTERACTION OF HYDROGENATED AMORPHOUS SILICON WITH INDIUM-DOPED ZINC OXIDE TRANSPARENT CONDUCTIVE FILMS.** Indium-doped zinc oxide films have been prepared by the spray pyrolysis technique using air as a carrier gas at atmospheric pressure. These films show the excellent optical and electrical characteristics of a transparent conductive coating, with a sheet resistance of  $15 \Omega/\square$  and an average optical transmission of about 88%. All the studied films show the wurtzite hexagonal crystalline structure. The results of Auger electron spectroscopy show that there was no reduction of the oxide film when an a-Si:H film was deposited by the plasma decomposition of silane at substrate temperatures in the range 150-300°C. A steep interface between the transparent conductive film and the hydrogenated amorphous silicon was observed. Also, it was found that the depth distribution of the constituent atoms zinc, oxygen and indium in the ZnO:In film was homogeneous. (Author abstract). 18 Refs.

Ortiz, A. (UNAM, Mexico City, Mex); Sanchez, A.; Falcony, C.; Farias, M.H.; Hirata, G.A.; Cota-Araiza L. *J Non Cryst Solids* v 103 n 1 6(II) 1988 p 9-13.

**094954 SELECTIVE WET AND DRY ETCHING OF HYDROGENATED AMORPHOUS SILICON AND RELATED MATERIALS.** The etch rate in aqueous KOH solutions and in  $\text{CF}_4\text{-O}_2$  plasmas was measured for hydrogenated amorphous silicon (a-Si:H) as a function of preparation conditions, and was compared to that of silicon in the hydrogen-free amorphous, poly-crystalline, and crystalline form. The rate depends strongly on the hydrogen content in wet etching and moderately in plasma etching. In analogy to crystalline silicon, the plasma etch rate of a-Si:H exhibits a strong dependence on the Fermi level. (Author abstract). 28 Refs.

Haller, I. (IBM, Yorktown Heights, NY, USA); Lee, Y.H.; Nocera, J.J.; Jaso, M.A. *J Electrochem Soc* v 135 n 8 Aug 1988 p 2042-2045.

**094955 APPLICATION OF THE EXTENDED PAIR APPROXIMATION TO HOPPING CONDUCTION IN r.f. SPUTTERED AMORPHOUS SILICON.** The real and imaginary parts of the frequency-dependent conductivities of amorphous silicon and hydrogenated amorphous silicon samples prepared by r.f. sputtering have been measured over temperatures between 40 and

200 K, where variable-range hopping is the dominant conduction mechanism. The data are interpreted using the extended pair approximation (EPA). This model gives an excellent qualitative fit to the data, describing well the scaling with the reduced frequency and the loss peak observed at the transition from non-dispersive to dispersive conduction. Quantitatively the agreement is less good. The discrepancies suggest that the conduction mechanism is not adequately described by electron tunnelling in a constant density of localized states. Various recent modifications to this basic model are discussed in the light of the data. (Edited author abstract). 35 Refs.

**094956 GAP STATES IN UNDOPED AMORPHOUS SILICON STUDIED BY BELOW-GAP MODULATED PHOTOCURRENT SPECTROSCOPY.** The energetic distribution and nature of dangling-bond states in undoped a-Si:H have been investigated by a newly developed gap-state spectroscopy which is based on the frequency-resolved spectrum of modulated photocurrent with below-gap photoexcitation. The energy scale is directly specified by the energy of the below-gap light populating the particular gap states. The result has led to the conclusion that the peak of the gap-state distribution associated with doubly occupied dangling bonds ( $D^-$ ) is located about 0.5 eV below the conduction band edge. The analysis for the pre-exponential factor of the thermal emission rate of electron from the  $D^-$  center suggests that the emission occurs in two stages through excited states. (Author abstract). 29 Refs.

Abe, K. (Osaka Univ, Toyonaka, Jpn); Okamoto, H.; Nitta, Y.; Tsutsumi, Y.; Hattori, K.; Hamakawa, Y. *Philos Mag B* v 58 n 2 Aug 1988 p 171-184.

**094957 ELECTRON MOBILITY IN AMORPHOUS SILICON UNDER DOUBLE INJECTION.** The transport of a pulse of photogenerated excess electrons has been investigated in a-Si  $p^+i-n^+$  junctions under forward bias in the presence of strong double injection. It is found that the electron drift mobility is completely independent of forward current densities of up to  $0.33 \text{ A cm}^{-2}$ . The results disagree with previous work of Silver et al., who observed an appreciable increase in electron mobility in the same range of current densities. It is suggested that the experimental disagreement arises from problems inherent in the voltage-step technique of mobility measurement used by these authors. (Author abstract). 10 Refs.

**094958 MOBILITY ACTIVATION ENERGY OF HYDROGENATED AMORPHOUS SILICON.** Recent experimental results indicate that the density of conduction band tail states  $g(E)$  in a-Si:H below the mobility edge  $E_c$  initially decreases linearly with increasing depth  $E_c - E$  and subsequently, below an energy  $E_0$ , decreases at an exponential rate. We examine the temperature range in which such a density of states may be expected to lead to a mobility activation energy  $E_\mu$  close to  $E_c - E_0$  and how  $E_\mu$  will behave at other temperatures. (Author abstract).

**094959 NON-OHMIC CONDUCTION IN GLOW-DISCHARGE A-Si:H FILMS.** Non-Ohmic conduction in undoped glow-discharge a-Si:H films has been studied using sandwich configurations. It is found that the conductivity at low temperatures is field-dependent and varies with field in the manner  $\sigma = \sigma_0 (T \exp(AeV/kT))$  over most of the field range used in the experiment, where A is a weak function of temperature T and V is the applied voltage. For voltages less than 1 V, the electric field does not change the temperature dependence of conductivity and the Mott  $T^{-1/4}$  law is obeyed

at low temperatures. The effect of light soaking is also described in this Letter and the results show that the low-temperature non-Ohmic conductivity remains almost unchanged after illumination while the high-temperature Ohmic conductivity drops significantly. (Author abstract). 22 Refs.

**094960 PHOTOCONDUCTIVITY MEASUREMENTS AS A TOOL FOR THE EVALUATION OF THE DENSITY OF STATES IN AMORPHOUS SILICON.** Photoconductivity measurements as a function of the temperature and light intensity were carried out on samples of hydrogenated and halogenated silicon films. The samples were deposited by rf glow discharge starting from a mixture of silicon tetrachloride and hydrogen. Experimental data were analyzed by using a theoretical model which assumes a density of states distribution having two exponential band tails and two gaussian distribution of states in the mobility gap. The model predicts a dependence of the photoconductivity as a function of the light intensity which agrees very well with the experimental one. (Author abstract). 10 Refs.

**094961 INTERBAND OPTICAL ABSORPTION IN AMORPHOUS SILICON.** The interband optical absorption characteristics of amorphous silicon films prepared by various techniques have been investigated. Above the main absorption edge, the absorption coefficient  $\alpha$  can be fitted to the 'Tauc' model  $(\alpha\hbar\omega)^{1/2} = C_0^{1/2} (\hbar\omega - E_g)$ . The experimental  $(\alpha\hbar\omega)^{1/2}$  versus  $\hbar\omega$  plots are generally piecewise linear, with an increase in slope above an energy  $E_u$ . Structure in the 'Tauc' plots is correlated with preparation conditions; the experimental results are consistent with a broadening of the density of states distribution at the band edges within a gap defined by  $E_u$ . The incorporation of bonded hydrogen into the a-Si network results in compositional disorder and deeper potential fluctuations that widen  $E_u$ . The bonded hydrogen increases both extrapolated energy gaps; the blue shift is proportional to the line density of hydrogen atoms over a wide range of bonded hydrogen concentrations. A unified model for the interband absorption edge in a-Si and a-Si:H is presented. (Author abstract). 4 Refs.

**094962 ELECTRON EQUILIBRATION IN A-SI:H BANDTAILS FOLLOWING PULSE EXCITATION.** The dynamic of excess carriers in hydrogenated amorphous silicon is investigated by a novel 'photoconductivity versus photoabsorption' analysis which combines cw and transient measurements. The technique enables one to establish experimentally whether and at which time excess carriers created by a light pulse reach a steady state equilibrium distribution. For a representative sample we find that the equilibrium is reached in about 40  $\mu\text{sec}$  and that the recombination and trapping rates are comparable. A theoretical model describing the dynamics is also presented. (Edited author abstract). 17 Refs.

**094963 MODULATED OPTICAL REFLECTANCE MEASUREMENTS ON AMORPHOUS SILICON LAYERS AND DETECTION OF RESIDUAL DEFECTS.** Modulated optical reflectance measurements on amorphous silicon layers are presented and a sample theoretical model, which is in good agreement with the experiment, is proposed. Further, the correlation between defects remaining after recrystallization of the amorphous layers and the measured modulated optical reflectance is

established. This measurement technique turns out to be useful for characterizing amorphous Si layers produced by ion implantation, for controlling the recrystallization of such layers, and for detecting residual defects. (Author abstract). 27 Refs.

**094964 HIGH RATE PRIMARY ION BEAM DEPOSITION OF A-Si:H FILMS.** Hydrogenated amorphous silicon films have been prepared by primary ion beam deposition with a new electrodeless rf ion source. The design of the ion source is described. The composition of the a-Si:H films has been determined by Rutherford backscattering, and the photoconductivity by the constant photocurrent method (CPM). The best a-Si:H films show photoconductivities of  $5 \times 10^{-5} (\Omega \text{ cm})^{-1}$ . The deposition rates were between 0.7 and 1.2 nm s<sup>-1</sup>. (Author abstract). 24 Refs.

**094965 GAP-STATE DISTRIBUTION IN a-Si: H BY MODULATED PHOTOCURRENT: SHALLOW-STATE-DEEP-STATE CONVERSION AND TEMPERATURE SHIFT OF THE ELECTRON-TRANSPORT PATH.** The distribution of localized states in a-Si:H above the Fermi energy has been determined by phase-shift analysis of modulated photocurrents. By use of a novel experimental technique the modulation frequency range could be greatly extended compared to conventional mechanical light chopping, revealing the gap-state distribution over an energy interval from 0.25 to 0.7 eV below the conduction-band edge. A shoulder at 0.35 eV and a peak at 0.55 eV below the band edge have been detected. Defect creation by strong illumination increases the peak and quenches the shoulder, indicating a shallow-state-deep-state conversion, and also proves the high sensitivity of this method. Data taken over a large temperature range from 110 to 480 K indicate an energy shift of the dominant electron-transport path with temperature. (Author abstract). 19 Refs.

**094969 a-Si:N:H PREPARED BY REACTIVE EVAPORATION IN AMMONIA VAPOUR.** The reactive evaporation of Si in an ammonia ambient has been used to produce a-Si:N:H thin films. These films are 'intrinsic-like' with low room-temperature conductivities ( $< 10^{-12} \text{ S cm}^{-1}$ ), high activation energies (0.9 eV), and high optical bandgaps (1.9 eV). Films prepared in this manner have been doped using co-evaporation of antimony (n type) and indium (p type). The addition of 2 at.% indium or antimony results in an increase in the room-temperature conductivity by eight and six orders of magnitude respectively. The undoped and doped samples are photoconductive when illuminated with a quartz-halogen source. (Author abstract) 8 Refs.

**094973 SAMPLE THICKNESS DEPENDENCE OF MINORITY CARRIER LIFETIMES MEASURED USING AN ac PHOTOVOLTAIC METHOD.** When Si wafer thickness is much smaller than the minority carrier diffusion length, the carrier lifetime, estimated by an ac photovoltaic method previously reported, has been shown to be restricted by the wafer thickness. The thickness dependence of the lifetime was measured on n-type Si wafers with thickness from 0.6 to 4 mm. The observed lifetimes ranged from 72.3  $\mu$ s to 1.1 ms and were in good agreement with those estimated theoretically. It was demonstrated that the bulk lifetime can be obtained with less than a 10% error when the sample thickness is 3.6 times larger than the diffusion length of the minority carriers. (Author abstract) 16 Refs.

**094974 MINORITY CARRIER TRANSPORT IN HEAVILY DOPED SILICON: FUNDAMENTAL EQUATIONS.** From fundamental principles, the equations that govern minority carrier transport and recombination in a heavily doped semiconductor are derived. The equations are based on three physically meaningful doping-dependent material parameters: minority carrier lifetime, mobility, and equilibrium concentration. To completely describe the problem, there is no need to use nonphysical entities like 'effective doping level' or 'apparent bandgap narrowing', as has become common in the silicon device literature. Under steady state, only two parameters, which are combinations of the three fundamental ones, are relevant to minority carrier transport and recombination. These findings have important implications for parameter measurements and for the modeling of heavily doped regions in devices. (Author abstract) 34 Refs.

**094975 EFFECT OF RADIATION DAMAGE ON CARRIER MOBILITY IN NEUTRON-TRANSMUTATION-DOPED SILICON.** The effect of radiation damage on neutron-transmutation-doped silicon of initially low- and high-resistivity materials has been studied by electrical property measurements. The materials were irradiated with a moderate thermal ( $0.45-1.0 \times 10^{18}$  neutrons cm<sup>-2</sup>) and fast ( $0.45-8.1 \times 10^{16}$  neutrons cm<sup>-2</sup>) neutron fluences. After irradiation, a small reduction of carrier mobility of the initially low-resistivity materials was observed, while the reduction of conductivity was large. The annealing behavior and temperature dependence of mobility of the materials indicate that the mechanism of carrier scattering is dominated by ionized impurities acting as point defects. The conductivity of those materials was recovered after annealing at 560°C for 60 min. In the range of annealing temperatures below 600°C, the carrier mobility of initially high-resistivity materials decreased together with the conductivity. The last result can tentatively be explained by a defect cluster model for fast-neutron-induced lattice damage. (Author abstract) 25 Refs.

**094977 CHEMICAL/MICROWAVE TECHNIQUE FOR THE MEASUREMENT OF BULK MINORITY CARRIER LIFETIME IN SILICON WAFERS.** A chemical/microwave technique for the measurement of bulk minority carrier lifetime in silicon wafers is described. This method consists of a wet chemical treatment (surface cleaning, oxidation in solution, and measurement in HF solution) to passivate the silicon surfaces, a laser diode array for carrier excitation, and a microwave bridge measuring system which is more sensitive than the microwave systems used previously for lifetime measurement. Representative experimental data are presented to demonstrate this technique. The result reveals that this method is useful for the determination of bulk lifetime of commercial silicon wafers. (Author abstract) 14 refs.

**094978 TRAPPING OF MINORITY CARRIERS IN THERMAL  $\text{U}^-$ -DONORS IN n-Si.** Theoretical studies are made on the trapping behavior of the semiconductor containing  $\text{U}^-$ -donors. The traps are divalent bistable thermal donors (BTD) with occupancy level inverted order of the first and second electrons ( $\text{U}^-$ -center). These results require the development of a new model of photoconductivity, which should involve both the existence of multiple-charge conditions for these centers and their inverted level order. This paper is mainly concerned with the analysis of the kinetics of the long-time component of photoconductivity (PC) related to the charge change of BTD. The theoretical analysis results are compared with the experimental data for the two sets of bistable thermal donors in n-Si. (Edited author abstract) 14 refs.

**094980 DIFFUSION LENGTH STUDIES IN SILICON BY THE SURFACE PHOTOVOLTAGE METHOD.** Diffusion lengths of minority carriers in the range 1-1200  $\mu\text{m}$  were measured in n and p type silicon single crystals with a wide range of resistivities by the surface photovoltage (SPV) method. Optimum measurement conditions were established by studying the dependence of measured diffusion length on the experimental conditions. The published absorption coefficient ( $\alpha$ ) data of Dash and Newman and Runyan were found inadequate, and a new determination of  $\alpha$  was made. (Edited author abstract) 35 refs.

**094981 MEASUREMENT OF GENERATION LIFETIME IN THIN SILICON LAYERS.** This paper describes an improved capacitance method for the mea-

surement of the minority carrier generation lifetime in the near surface region in thin silicon layers. The technique provides a simple experimental means for evaluating interferences in the leakage current, such as diffusion from the quasi-neutral bulk and peripheral generation, permitting a more accurate determination of the lifetime. Additional, related capacitance measurements are performed on adjacent circular capacitors of differing radii to quantify the extent of peripheral generation. Results are presented demonstrating application of the method and illustrating the magnitude of these interferences. These results indicate that the accurate determination of the generation lifetime in current, high quality silicon necessitates the use of experimental means, such as the technique described, in order to quantify interference components in the leakage current. Assumptions underlying the technique and limitations in its use are discussed. (Edited author abstract) 20 refs.

**094982 SURFACE AND VOLUME DECAY PROCESSES IN SEMICONDUCTORS STUDIED BY CONTACTLESS TRANSIENT PHOTOCONDUCTIVITY MEASUREMENTS.** Excess charge carrier kinetics in moderately doped pSi wafers were investigated with a contactless transient photoconductivity method, i.e. the time-resolved microwave conductivity (TRMC) method. The surface structure of the wafers was changed by etching and polishing, the volume structure by irradiation with high-energy electrons. Comparison of the photoconductivity decay after excitation by strongly absorbed light and by weakly absorbed light was used to distinguish between surface and volume decay processes. The experimental results deviate from predictions based on a linear surface decay rate. These results are discussed and suggestions are made for the use of transient photoconductivity measurements to characterize semiconductor wafers. (Author abstract) 15 refs.

**094985 DETERMINATION OF MINORITY CARRIER MOBILITY IN SILICON FROM STATIONARY AND TRANSIENT LIFETIME MEASUREMENT.** The minority carrier diffusion coefficient in Si as a function of dopant density is evaluated by comparing the

diffusion length as obtained by a steady state method (using a combination of the photoelectromagnetic (PEM) effect and the steady state photoconductivity (PC) effect) and a lifetime obtained by the photoconductivity decay (PCD) method. Within the limits of the experimental data dispersion, the electron minority diffusion coefficients are comparable to the majority ones in the doping range  $3 \times 10^{14} < N_A \text{ LS } 3 \times 10^{17} \text{ cm}^{-3}$ . The minority hole diffusion coefficients are about 36 percent higher than the majority hole coefficients in the doping range  $6.1 \times 10^{13} < N_D < 7.1 \times 10^{16} \text{ cm}^{-3}$ . (Author abstract). 21 Refs.

**094986 SURFACE-RECOMBINATION AND DOPING EFFECTS ON THE MINORITY CARRIERS IN POLYCRYSTALLINE SILICON.** A scanning laser microscope was used in a spatially resolved photoconductivity experiment to determine the minority-carrier diffusion length ( $L$ ) and surface-recombination velocity at grain boundaries ( $S_{GB}$ ) in (i) n- and p-type Wacker polysilicon and (ii) neutron-transmutation-doped Metron polysilicon as a function of beam intensity. Different values of  $L$  were measured on opposite sides of the grain boundaries. For the Metron samples,  $L$  was measured at the same grain boundary using a series of samples doped to different levels. These samples had dopant concentrations between  $10^{13}$  and  $10^{17} \text{ atoms/cm}^3$ .  $L$  was found to decrease from 50 to 5  $\mu\text{m}$ , with decreasing beam intensity, reaching a constant value at low beam intensities.  $L$  was also found to remain relatively unchanged for low dopant concentrations. The  $S_{GB}$  values were found to increase with increasing beam intensity in both Wacker and Metron samples, ranging between  $10^4$  and  $10^5 \text{ cm/s}$ .  $L$  was also measured with a light-beam-induced-current technique (perpendicular geometry) and found to be in close agreement with values obtained using the photoconductivity technique. (Author abstract). 17 Refs.

**094987 INJECTION AND RECOMBINATION CURRENTS IN a-Si:H STRUCTURES.** Both, theoretical and experimental investigations of current-voltage characteristics of a-Si:H structures (Pt-i-n, p-i-n) are carried out. A choice in favor of the double-carrier injection mechanism is substantiated. A theory of G-R currents is applied to a semiconductor with a continuous density of localized states in the mobility gap. (Author abstract). 10 Refs.

Golikova, O.A. (Acad of Sciences of the USSR, Leningrad, USSR); Mezdrogina, M.M.; Feoktistov, N.A.; Sorokina, K.L.; Kazanin, M.M.; Karageorgiy-Alkalaev, P.M.; Leiderman, A.Yu. *Phys Status Solidi A* v 108 n 1 Jul 1988 p 323-329.

**094988 TEMPERATURE DEPENDENCE OF MINORITY ELECTRON MOBILITY AND BANDGAP NARROWING IN P+ SI.** By fabricating wide-base-width lateral and vertical bipolar transistors with uniformly heavily doped p-type bases, both bandgap narrowing (BGN) and minority electron mobility ( $\mu$ ) have recently been measured. These measurements have been extended to temperatures from 90 to 390 K. Minority-electron mobility increases strongly as temperature decreases, the most heavily doped layers exhibiting the strongest mobility increase with decreasing temperature. Bandgap narrowing decreases linearly with decreasing temperature down to roughly 240 K and levels off. For a sample doped  $2 \times 10^{19} \text{ cm}^{-3}$ , the BGN is 15 meV lower at 100 K and 25 meV higher at 390 K than at room temperature. Both these results suggest that it is possible

to construct higher performance n-p-n bipolar transistors (with heavily doped bases), for low-temperature operation, than was previously believed. 2 refs.

**094989 MINORITY-CARRIER LIFETIME ANALYSIS OF SILICON EPITAXY AND BULK CRYSTALS WITH NONUNIFORMLY DISTRIBUTED DEFECTS.** Existing analyses of the pulsed response of a MOS capacitor for minority-carrier lifetime determination result in a lifetime value averaged over most of the depletion region width. The authors present an analysis of MOS capacitance-versus-time data that enables minority-carrier generation lifetime to be plotted as a function of depletion-region depth. The technique is shown to be useful for samples with bulk or buried interfacial layer defects that have defect-free surfaces. Data are presented for intrinsically getterd bulk crystals and extrinsically getterd Si (2% Ge) epitaxial layers with misfit dislocations. For samples that do have uniform lifetimes, the measurement time required for determining carrier lifetime is reduced by more than an order of magnitude. 11 refs.

**094990 N-TYPE SIPOS AND POLY-SILICON EMITTERS.** N-type SIPOS and poly-silicon emitters on silicon show potential for improved minority carrier blocking properties over conventional diffused emitters. This paper discusses experiments designed to elucidate the physical mechanisms responsible for this improvement and to optimize the process conditions. Emitters both with and without an intentionally grown chemical oxide under the SIPOS or poly-silicon film are investigated. Both poly-silicon and SIPOS emitters, in their optimized form, can achieve  $J_{oc}$  of less than  $2 \times 10^{-14}$  A/cm<sup>2</sup>, an improvement of several decades over shallow diffused emitters. (Author abstract) 6 refs.

Kwark, Y.H. (Stanford Univ, Stanford, CA, USA); Swanson, R.M. *Solid State Electron* v 30 n 11 Nov 1987, New Dev in the Phys of Homo- and Heterojunctions, US-Belg Jt Semin, Louvain, Belg, May 28-30 1986 p 1121-1125.

**094991 MODELLING OF MINORITY-CARRIER TRANSPORT IN HEAVILY DOPED SILICON EMITTERS.** The transport and recombination of minority carriers in heavily doped emitters plays a crucial role in the performance of silicon bipolar transistors and solar cells. In the past, only order-of-magnitude prediction of the value of the current injected into a heavily doped emitter was possible. The limitations to a more accurate modelling stemmed from: (1) the incomplete understanding of the physics of minority carriers in heavily doped semiconductors; (2) the lack of precise measurements of the relevant material parameters; (3) the difficulties encountered with the modelling of transport and recombination in non-homogeneously doped regions; and (4) problems with the characterization of 'real' emitters of bipolar devices. This paper reviews recent experimental and theoretical efforts that addressed some of these issues, with the goal of being able to achieve accurate modelling of the current injected into an arbitrary heavily doped region in a silicon device. (Author abstract) 67 refs.

**094992 TUNING THE EFFECTIVE BANDGAP OF A SILICON DOPING SUPERLATTICE.** In this paper, we examine the tunability of the effective bandgap and carrier concentration in a silicon-doping superlattice with narrow n<sup>+</sup>-doped layers and wide p-doped layers. Quanti-

tative tunability parameters are defined and their variation with dopant concentration and temperature are calculated self-consistently in the effective mass and Hartree approximations. It is found that the tunabilities increase as doping is increased or as temperature is decreased. (Author abstract) 9 refs.

**094993 MICRO-DEFECT EFFECTS ON MINORITY CARRIER LIFETIME IN HIGH PURITY DISLOCATION-FREE SILICON SINGLE CRYSTALS.** The effects of various kinds of micro-defects on minority carrier lifetime in high purity dislocation-free silicon single crystals were studied by float-zoning, photoconductivity attenuation and copper decoration combined with selective etching, X-ray topography and electron-beam-induced-current analysis. We found that swirl defects (A or B type) and unidentified frozen-in defects are responsible for limiting minority carrier lifetimes in high purity silicon crystals. The A-type defect was found to be a recombination center with an effective diameter of approximately 30-40  $\mu$ m. By altering crystal growth conditions such as growth rate and diameter, various thermal gradients and cooling rates were attained. These affected the micro-defect characteristics and hence the lifetimes of the crystals grown. (Author abstract) 17 refs.

**094994 APPLICATION OF AUGER ELECTRON SPECTROSCOPY AND PRINCIPAL COMPONENT ANALYSIS TO THE STUDY OF THE Pd/c-Si AND Pd/a-Si INTERFACES.** An analysis is made of Pd/c-Si and Pd/a-Si interfaces using principal-component analysis (PCA) of the Auger line shapes combined with a technique known as target transformation (TT), which, when used after PCA, allows the extraction of spectra for unidentified compounds in a depth profiling. The results obtained reveal the existence of a Si-rich compound in both interfaces, while Pd<sub>2</sub>Si was found to be spontaneously formed (i.e., without annealing) only at the Pd/a-Si interface. 24 refs.

**094995 SOLID PHASE EPITAXY OF LPCVD AMORPHOUS SILICON FILMS.** Solid phase epitaxy of 190 nm amorphous silicon films deposited by LPCVD at 545°C on silicon substrates was studied. A single silicon implantation at 190 keV was performed to initiate the SPE<sup>1</sup> process. The effect of the silicon dose in the range  $1 \times 10^{15}$ - $1 \times 10^{16}$  cm<sup>-2</sup> on the quality of the epitaxial layer was studied by TEM. Epitaxial crystallization of the amorphous silicon was obtained for a silicon dose greater than  $4 \times 10^{15}$  cm<sup>-2</sup> after annealing for 65h at 650°C. The main defects in the film were dislocations and microtwins. The density of defects decreased after annealing at 950°C for 30 min. In addition to defects in the epitaxial layer a residual dislocation band was observed in the substrate. The depth and width of this dislocation band is determined by the silicon dose. **094996 DIFFUSION LENGTH MEASUREMENTS ON PLASMA-SPRAYED POLYCRYSTALLINE SIL-**

**ICON SUBSTRATES AND ON SILICON GROWN ON THEM BY CHEMICAL VAPOUR DEPOSITION.** The plasma spray technique was used to obtain p-type polycrystalline silicon deposits 200  $\mu$ m-2 mm thick and of area 1 cm<sup>2</sup>. Silicon layers 50  $\mu$ m thick were grown on these deposits by chemical vapor deposition. The electronic diffusion length of plasma-sprayed silicon was found to be in the range 9-16  $\mu$ m whereas it increased to 28  $\mu$ m in the layer grown by chemical vapor deposition. (Author abstract) 8 refs.

**094997 THERMODYNAMIC EQUILIBRIA IN THE Si-H-Cl AND Si-H-Br SYSTEMS.** Equilibrium calculations were performed for the Si-H-Cl and Si-H-Br systems. Gibb's free energy of formation data from the JANAF tables were used for all species, with the exception of that for SiCl<sub>3</sub>(g). Three conditions of interest to the electronics industry were examined: epitaxial silicon deposition, polysilicon deposition, and conversion of SiX<sub>4</sub>(g) to SiH<sub>3</sub>X<sub>3</sub>(g). Calculated results are presented graphically: partial pressures as a function of temperature; and silicon content of the gas phase as a function of initial starting concentrations. (Edited author abstract) 23 refs.

**094998 CO<sub>2</sub>-LASER-INDUCED CHEMICAL VAPOUR DEPOSITION OF POLYCRYSTALLINE SILICON FROM SILANE.** Silicon dots have been deposited on silicon-coated quartz substrates by continuous wave CO<sub>2</sub>-laser-induced decomposition of silane. The deposited material was determined by micro Raman scattering to be polycrystalline silicon. The height of the silicon dots was measured as a function of output laser power and irradiation time. The growth rate of silicon dots having a gaussian profile was found to be proportional to silane pressure and laser power. The laser power required for silicon melting (1683 K) was measured under specific experimental conditions. The substrate temperature could be calculated for any laser power assuming a linear temperature dependence on this power. The growth rate of silicon dots was found to be proportional to the substrate temperature. The growth kinetics of silicon dots may be limited by the number of collisions between 'cold' silane molecules and the heated zone of substrates. A reaction mechanism based on this assumption is proposed in this paper. (Author abstract) 22 refs.

**094999 INITIAL STEPS IN THE PHOTOCHEMICAL VAPOUR DEPOSITION OF AMORPHOUS SILICON.** The overall process of chemical vapour deposition (CVD) is divided into reaction steps in the gas phase and on the solid-state surface. Energy input and primary reaction of the gas phase educt molecules constitute the initial steps considered in this paper. Special emphasis is placed on the photochemical vapour deposition (photo-CVD) of amorphous silicon from SiH<sub>4</sub> and Si<sub>2</sub>H<sub>6</sub> including uv single photon and ir multiple-photon activation. Experimentally convenient excitation processes and energetically possible primary decomposition pathways are summarized, compared, and discussed with respect to the selectivity of the chemical reactions. Finally the current status of photo-CVD is briefly presented. (Author abstract) 66 refs.

**095000 THREE-DIMENSIONAL FLOW EFFECTS IN SILICON CVD IN HORIZONTAL REACTORS.** Numerical modeling of Si homoepitaxial deposition from SiH<sub>4</sub> in the horizontal reactor has been undertaken employing the steady-state, fully parabolic flow approxi-

mation for the heat, momentum, and mass-transfer equations. Reactants are assumed to be dilute in their carrier gas. The resulting set of partial differential equations are discretized using finite elements and solved using the method of lines. The effect of a third dimension, the side temperature boundary conditions, and natural convection are explored. Given recent kinetics data on the silane decomposition and silylene insertion reactions, it is shown that a quasi-thermodynamic equilibrium exists in the heated region above the surface, at least for hydrogen gas ambients. (Edited author abstract) 63 refs.

**095001 INITIAL STAGE OF LASER-INDUCED SELECTIVE CHEMICAL VAPOR DEPOSITION OF SILICON.** Spatially selective chemical vapor deposition has been achieved by ArF excimer laser (193 nm) irradiation through a metal mask in a  $\text{Si}_2\text{H}_6 + \text{He}$  gas mixture. The selective deposition kinetics has been found to be controlled by a nonthermal process and has been explained in terms of the Langmuir-Hinshelwood mechanism. Both surface migration of adsorbed radicals and desorption of reaction products appear to be enhanced with the laser irradiation, leading to a selective nucleation of silicon. (Author abstract) 9 refs.

Tanaka, Takeshi (Hiroshima Univ, Higashihiroshima, Jpn); Deguchi, Koji; Hirose, Masataka. *Jpn J Appl Phys Part 1* v 26 n 12 Dec 1987 p 2057-2060.

**095002 CONVECTION AND MASS-TRANSPORT IN LASER-INDUCED CHEMICAL VAPOR DEPOSITION.** Gas flow and energy and species transport in laser-induced chemical vapor deposition (LICVD) of amorphous silicon films by silane pyrolysis are analyzed by finite element analysis of a two-dimensional model for the process. Spatial nonuniformity of the deposited film is shown to result from diffusion controlled transport of products between the beam and substrate. Deposition profiles are affected by buoyancy-driven convection only at increased gas pressures. Horizontal orientation of the reactor with respect to gravity is optimal because the stagnation-like flow, that results adjacent to the substrate, enhances mixing, and smoothes the film profile. (Author abstract) 40 refs.

Patnaik, S. (MIT, Cambridge, MA, USA); Brown, R.A. *J Electrochem Soc* v 135 n 3 Mar 1988 p 697-706.

**095003 PREPARATION AND PROPERTIES OF a-Si FILMS DEPOSITED AT A HIGH DEPOSITION RATE UNDER A MAGNETIC FIELD.** An rf plasma decomposition of  $\text{SiH}_4$  under a magnetic field was investigated. It was confirmed by the optical emission spectra that a high-electron-density plasma can be produced under a magnetic field. High-quality a-Si films with a photosensitivity of  $\sigma_{ph}/\sigma_d$  of  $7 \times 10^5$  were obtained at a high deposition rate of  $10 \text{ Å/s}$  under the magnetic field. The a-Si solar cells with i-layers deposited at a high deposition rate under a magnetic field have a higher open-circuit voltage and a higher recombination efficiency than those without the magnetic field; a conversion efficiency of 10.1% under AM1 ( $100 \text{ mW/cm}^2$ ) illumination was obtained at a deposition rate of  $10 \text{ Å/s}$ . The rf plasma decomposition of  $\text{SiH}_4$  under a magnetic field is thought to be very suitable for fabricating a-Si solar cells with a high conversion efficiency at a high deposition rate. (Author abstract) 9 refs.

**095004 PROCESS CHARACTERIZATION AND MECHANISM FOR LASER-INDUCED CHEMICAL VAPOR DEPOSITION OF a-Si:H FROM  $\text{SiH}_4$ .** The dependence of a-Si:H film deposition by laser-induced decomposition of  $\text{SiH}_4$  on the different process variables

is studied. The gas phase temperature in the beam center, produced by  $\text{CO}_2$  laser irradiation in parallel configuration, is estimated using a simple energy and balance model. The surface temperature is measured with high accuracy employing a Ni sensor ( $250^\circ\text{--}400^\circ\text{C}$ ). The deposition rate and film properties such as the hydrogen content and the optical energy gap are determined as a function of these parameters. The production of  $\text{H}_2$  (approximately 10%),  $\text{Si}_2\text{H}_6$  (approximately 2%), and  $\text{Si}_3\text{H}_8$  in the gas phase during laser irradiation is proved by a mass spectrometric analysis. The chemical reaction processes induced in the gas phase and at the surface are discussed. A mechanism explaining the main features of the complicated chemistry involved is developed. (Author abstract) 31 refs.

**095005 NEW HIGH PURITY DOPING SOURCE FOR CVD Si-Ga EPITAXY.** A new CVD growth chemistry has been developed for producing very pure and high crystalline-quality gallium-doped silicon epitaxy. Gallium trichloride,  $\text{GaCl}_3$ , has been employed as an improved precursor to the currently accepted organometallic gallium source, trimethyl gallium,  $(\text{CH}_3)_3\text{Ga}$ . In contrast to trimethyl gallium, this metal halide doping source does not cause carbon contamination of the epitaxial layer. Much more abrupt layer-to-layer transition regions have been demonstrated. Data on the electrical and crystalline characteristics of  $\text{GaCl}_3$ -grown Si:Ga layers are presented. The current doping limit of  $4 \times 10^{17} \text{ cm}^{-3}$  obtained with this chemistry under normal CVD growth conditions is well below the solubility limit and is indicative of the unusual surface chemistry involved in doping. Results of experiments to elucidate the doping mechanism are discussed. (Author abstract) 13 refs.

**095006 PREFERRED ORIENTATION OF SILICON FILMS GROWN BY LPCVD AT RELATIVELY LOW TEMPERATURES.** Polycrystalline silicon thin films prepared by low pressure chemical vapour deposition (LPCVD) are of great interest in integrated circuitry. The most recent interest was motivated by relatively low temperature processes for obtaining silicon films on insulators for active matrix addressing of liquid crystal displays. This paper presents studies concerning the exact orientational relationship of the grains and a detailed view of the initial stages of growth following pyrolysis. Transmission electron microscopy investigations to define the structure were performed. 8 refs.

**095007 VERY-LOW-TEMPERATURE SILICON EPITAX BY PLASMA-CVD USING  $\text{SiH}_4\text{-PH}_3\text{-H}_2$  REACTANTS FOR BIPOLAR DEVICES.** A novel plasma-CVD process has been developed for growing specular silicon epitaxial layers at very low temperatures of approximately  $200^\circ\text{C}$ . The epitaxial layers were deposited from  $\text{SiH}_4\text{-PH}_3$  gases diluted with  $\text{H}_2$  on single-crystal substrates just after being etched in a HF dip. The highest electron mobility and lowest resistivity of the  $n^+$ -layers were  $30 \text{ cm}^2/\text{V}\cdot\text{s}$  and  $4 \times 10^{-4} \Omega\cdot\text{cm}$ , respectively. This technology has been successfully applied to fabricate bipolar transistors with a high current gain of 370. (Author abstract) 9 refs.

**095008 GROWTH OF ORIENTED Si FILM ON QUARTZ FROM  $\text{Si}_2\text{H}_6$  BY THERMAL AND PHOTO-CVD USING A  $\text{D}_2$  LAMP.** Polycrystalline Si films have been grown on fused quartz plates at  $500\text{--}650^\circ\text{C}$

from  $\text{Si}_2\text{H}_6$  by thermal CVD and photo-CVD using a  $\text{D}_2$  lamp. The thermal and photo-CVD films prepared above  $575^\circ\text{C}$  are highly  $\langle 100 \rangle$ -oriented but the films at  $545$  and  $560^\circ\text{C}$  are  $\langle 110 \rangle$ -oriented. This tendency is more remarkable in the photo-CVD than in the thermal CVD. These orientations change little in depth, but the orientation horizontal to the film plane is random. (Author abstract) 16 refs.

**095009 IN SITU IR SPECTROSCOPIC STUDY OF a-Si:H FILMS GROWING UNDER PHOTO-CHEMICAL VAPOR DEPOSITION CONDITION.** Polarization modulation infrared spectroscopy has been successfully applied for in situ observations of a-Si:H films growing under photo-chemical vapor deposition conditions. The thin films exhibited absorption bands arising from  $\text{SiH}_3$  or  $\text{SiH}_2$  species, depending upon the substrate temperature. Whereas the mass thickness of the film deposited at  $293 \text{ K}$  increased in proportion to the deposition time, the IR absorption intensity of  $\text{SiH}_3$  species decreased in rate when the film grew beyond  $15 \text{ Å}$  in thickness, showing that the concentration of the  $\text{SiH}_3$  species becomes reduced with the deposition time. Although the band ascribable to the Si-O stretching vibration could not be observed during the deposition, it grew when the film was exposed to air. This fact suggests that the origin of the oxygen incorporated in the film is mainly atmospheric oxidizing agents. (Author abstract) 17 refs.

**095010 ANALYTICAL STUDY ON INTERFACE OF EPITAXIAL Si IN Si SUBSTRATE GROWN BY  $\text{CO}_2$  LASER CVD.** The Si epitaxial films were grown on (100) Si substrates at  $650^\circ\text{C}$  by  $\text{CO}_2$  laser CVD using  $\text{SiH}_4$  gas. The authors discuss the initial stage of Si epitaxial growth by the crystallinity measurements of the region near the interface and the effect of the concurrent radiation of UV light onto Si substrate during the epitaxial growth by the  $\text{CO}_2$  laser CVD. The improvement of crystallinity of the epitaxial films is also discussed. The crystallinity measurement was carried out by Rutherford backscattering spectrometry (RBS) and transmission electron microscopy (TEM). The high density defect region of approximately  $150 \text{ nm}$  in thickness from the interface was observed in the case of the films grown by  $\text{CO}_2$  laser CVD at  $700^\circ\text{C}$ , and this kind of region was eliminated by the coradiation of UV light during the epitaxial growth. (Edited author abstract) 13 refs.

**095011 EPITAXIAL GROWTH OF IN SITU DOPED SILICON BY LPCVD.** This paper analyzes the first results obtained in the deposition of in situ doped epitaxial silicon under low pressure conditions. A LPCVD system at high temperatures using a hot wall reactor was used for the experiments. The results obtained on the impurity concentration in the grown layers indicate its strong dependence on the partial pressure of diborane and hydrogen. Furthermore, a difference in the growth rate has been found when diborane is introduced into the initial mixture, which depends on the source used and appears to be due to the presence of HCl in the gas phase. (Author abstract) 8 refs.

Dominguez, C. (CSIC, Madrid, Spain); Pastor, G.; Dominguez, E. *Vacuum* v 37 n 5-6 1987, VI Span Conf on Vac and Its Appl, Madrid, Spain, Dec 1985 p 407-409.

**095012 LOW PRESSURE SILICON EPITAXY IN A HOT-WALL REACTOR.** An attempt has been made to elucidate the mechanism followed during silicon epitaxial deposition at low pressures and high temperatures

when varying the silicon source. Although a similar reaction for both sources appears to exist, i.e. pyrolysis decomposition in the gas phase, the heterogeneous deposition mechanism may be different, for the different sources. This is due to the fact that, in the case of trichlorosilane, the co-generation of HCl with SiCl<sub>2</sub> in the gas phase makes possible a competition between etching and growth, whereas, in the case of dichlorosilane, the absence of HCl in the gas phase permits a single deposition mechanism. In order to explain the actual mechanism for each of the sources it is necessary to carry out an in-depth study of the various parameters governing deposition. 9 refs.

Dominguez, C. (CSIC, Madrid, Spain); Dominguez, E. *Vacuum* v 37 n 5-6 1987, VI Span Conf on Vac and Its Appl, Madrid, Spain, Dec 1985 p 419-421.

**095013 LOW-TEMPERATURE CRYSTALLIZATION OF IN SITU PHOSPHORUS-DOPED LOW-PRESSURE CHEMICAL-VAPOUR DEPOSITED AMORPHOUS SILICON.** A method has been developed for producing low-resistivity phosphorus-doped polysilicon films with a minimum thermal budget. The method involves low-pressure chemical-vapor deposition of amorphous silicon at 500°C followed by crystallization at 650°C. Films formed in this manner are compared to films deposited polycrystalline at 627°C. In both cases, in situ doping is achieved by addition of PH<sub>3</sub> diluted in SiH<sub>4</sub> to the gas mixture. For a given SiH<sub>4</sub>:PH<sub>3</sub> flow ratio, the phosphorus concentration determined from secondary-ion mass spectroscopy is four times larger in the amorphous-deposited material. Moreover, the resistivity is substantially lower in this material even when the dopant concentrations are similar. The latter result may be due in part to reduced dopant segregation to grain boundaries. The internal strain determined from the Raman line width is larger in the polycrystalline-deposited material but could be reduced by high-temperature annealing. (Author abstract) 7 refs.

**Cleaning** See Also SEMICONDUCTING GALLIUM ARSENIDE—Growth.

**095014 SI SURFACE CLEANING BY Si<sub>2</sub>H<sub>6</sub>-H<sub>2</sub> GAS ETCHING AND ITS EFFECTS ON SOLID-PHASE EPITAXY.** Si surface cleaning with Si<sub>2</sub>H<sub>6</sub>-H<sub>2</sub> was studied for lateral solid-phase epitaxy (L-SPE) of CVD a-Si films. The cleaning was performed at 850°C, which is considerably lower than the previously-reported H<sub>2</sub>-cleaning temperature (1100°C). This is because etching of native oxide is enhanced by a reaction between oxide and Si-atoms dissociated from Si<sub>2</sub>H<sub>6</sub>. The effects of Si<sub>2</sub>H<sub>6</sub>-cleaning on L-SPE were studied using a Si (100) wafer with SiO<sub>2</sub> stripes. After Si<sub>2</sub>H<sub>6</sub>-cleaning or H<sub>2</sub>-cleaning at 850°C, CVD a-Si films are deposited on the wafers, then crystallized by annealing (575°C). An H<sub>2</sub>-cleaned sample showed imperfect L-SPE because of a residual native-oxide layer at the a-Si/substrate interface. In the Si<sub>2</sub>H<sub>6</sub>-cleaned sample, the native-oxide layer was removed, and L-SPE growth was observed uniformly in the wafer. Si<sub>2</sub>H<sub>6</sub>-cleaning at 850°C is applicable for substrates with abrupt impurity distribution. (Author abstract) 18 refs.

**095015 CHANGES IN ELECTRICAL CHARACTERISTICS OF Al-Ti CONTACTS ON SILICON.** The electrical characteristics of Al-Ti metallization on p, n, p<sup>+</sup> and n<sup>+</sup> silicon were studied. The contact specific resistance or the electron and hole energy barriers were determined. The conductance-reverse voltage measurement technique was used to reveal the contact non-uniformities (microplasma-type effects). SEM micrographs provided a picture of the contacts surface geometry. All these

results showed that when the Ti barrier disappears due to the Al-Ti interaction the entire contact behavior resembles that of an Al/Si contact. This drastic change of the contacts properties, as well as the surface degradation, are therefore confirmed by a consistent investigation of the electrical characteristics. The paper presents the results of some investigations on Ti and Ag-Ti metallization systems. (Edited author abstract) 23 refs.

**095016 ANALYSIS OF COINCIDENCE LOSSES FOR A MONITOR OF PARTICLE CONTAMINATION ON SURFACES.** A widely used instrument (manufactured by InspeX, Incorporated) for detecting, sizing, and counting particles on silicon wafer surfaces determines particle size by the number of pixels on a vidicon-type screen that are activated by light scattered from particles during oblique observation of perpendicular illumination. The authors present a method for estimating the fraction of the particles that are not involved in coincidence. The full solution for the fraction of particles in any size category overlapped by those in any other category is presented. Two limits are developed: one for particles all the same size (that is, each giving the same response) and one for particles of very different sizes, the smallest being much more numerous. (Edited author abstract) 5 refs.

**095017 REMOVAL PROCESSES FOR DAMAGE AND CONTAMINATION AFTER CF<sub>4</sub>/40% H<sub>2</sub> REACTIVE ION ETCHING OF SILICON.** State of the art of RIE reactors, nature of damage and contamination introduced, their effects and controls are reviewed. The defect model as conceived on this basis is presented. The highly selective etching of SiO<sub>2</sub> relative to Si is done by reactive ion etching with CF<sub>4</sub>/40% H<sub>2</sub>. The damage and contamination introduced in Si are characterised by Al/p-Si Schottky diodes fabricated on dry etched Si wafers. The dry etching is found to convert an Al/p-Si ohmic contact into a rectifying one. Various removal processes of damage and contamination after dry etching are tried to restore the original behaviour of the diodes. The results indicate that ashing, (RF sputter etching in N<sub>2</sub> ambient) followed by HF dip are sufficient to restore the surface. The effects of omissions of RF sputter etching in N<sub>2</sub> ambient and HF dip are discussed. An alternative process of thermal oxidation of dry etched Si wafers in an O<sub>2</sub>/TCE ambient at 1000°C for 15 mins followed by HF dip is seen to recover the surface. This is confirmed by lifetime studies made on post-oxidised Si wafers. The latter process consumes more silicon. The suitability of the process for VLSI fabrication is discussed. (Edited author abstract) 54 refs.

Singh, Awatar (CEERI, Pilani, India). *Microelectron J* v 18 n 5 Sep-Oct 1987 p 13-24.

**095018 INVESTIGATION OF SURFACE CONTAMINATION ON SILICON WAFERS WITH SIMS.** An analytical approach for investigation of surface contaminants with SIMS (secondary ion mass spectrometry) is proposed. The major problem is the presence of the contaminants only in the native oxide (thickness approximately 1.5 nm). This means that analysis has to be performed in a surface zone smaller than the implantation depth of the primary ions. Chemical matrix effects and a changing erosion rate are encountered owing to the native oxide and the dynamic process of primary ion implantation and sputtering. Owing to the necessity of analyzing extremely thin surface layers very slow sputtering has to be applied (1-10 monolayers per min.). As a consequence the secondary ion intensities are low and hydrocarbon species interfere with the elements to be analyzed. For the identification of the secondary ion signals the evaluation

of isotopic ratios determined with low mass resolution ( $M/\Delta M \approx 350$ ) is combined with measurement of high resolution mass spectra. (Author abstract) 20 refs.

**095019 CONTAMINATION OF SILICON SURFACES EXPOSED TO CHF<sub>3</sub> PLASMAS AN XPS STUDY OF THE FILM AND THE FILM-SURFACE INTERFACE.** Si surfaces previously exposed to CHF<sub>3</sub> plasmas (RIE mode) have been characterized by x-ray photoelectron spectroscopy (XPS). Plasma exposure of a clean Si surface leads to the deposition of a C,F containing film. The C<sub>1s</sub> XPS spectrum reveals various bonding states of carbon, including CF<sub>3</sub>, CF<sub>2</sub>, CF, C-CF<sub>x</sub>. The [C]/[F] ratio and the relative concentrations of the different carbon species do not depend on exposure time. For very short exposure times (approximately 1s) the polymer deposition is instantaneous and the film substrate interface is accessible. It consists of a SiO<sub>x</sub> layer - probably the remains of the native oxide layer existing on the substrate - and C- and Si-F species implanted within or below the SiO<sub>x</sub> layer. The ion bombardment is thus proved to be an essential parameter of the polymer deposition initial mechanism. (Author abstract) 37 refs.

**095020 SURFACE CONTAMINATION DETECTION BELOW THE ppb RANGE ON SILICON WAFERS.** The atomic absorption technique has been used to detect trace impurity contamination in silicon wafers at different stages of processing. Suitable wafer etching by quantitative silicon removal followed by impurity concentration made it possible to reach significant detection limits for all the interesting contaminants, including Fe, Cr, Cu, Ni, K, Zn, Co, Mn, each present at levels below 10<sup>12</sup> atoms/cm<sup>2</sup>. The number of contaminant species can be further increased and the detection limits improved. The extent to which correlations are possible with other less direct methods is discussed. **095021 REMEASUREMENT OF A SILICON LATTICE PERIOD.** Optical interferometry of a silicon lattice period is an important link between macroscopic and microscopic lengths as well as between low-energy and high-energy spectroscopies. An evident discrepancy between two pre-1982 measurements has limited the effective application of these results. Very recent results are reported in a preliminary way that appear to further understanding and to remove this discrepancy. 11 refs.

**095022 DEPTH DEPENDENCE OF NUCLEATION IN IMPLANTED POLYCRYSTALLINE SILICON FILMS ON SiO<sub>2</sub>.** Silicon films can be prepared for silicon-on-insulator (SOI) applications by amorphizing a polycrystalline silicon film by ion implantation and then crystallizing it by a subsequent low-temperature anneal. Crystallization of a 1500 Å polycrystalline silicon film

self-implanted at an energy of 100 keV and a dose of  $2 \times 10^{15}$  ions/cm<sup>2</sup> is found to be due to the nucleation of crystallites at or near the top surface. Nucleation is believed to be due to small crystalline regions (clusters) which survive implantation. Such clusters will exist predominantly at the depth corresponding to the least implant damage which, for this implantation-target combination, is at the top surface. 13 refs.

#### Crystallization See Also TRANSISTORS—Thin Films.

**095023 LARGE SPONTANEOUS NUCLEATION RATE IN IMPLANTED POLYCRYSTALLINE SILICON FILMS ON SiO<sub>2</sub>.** One method of preparing silicon films for silicon-on-insulator (SOI) applications is to amorphize a polycrystalline film by implantation and then crystallize it by a low temperature anneal. The experiment examined crystallization behavior to determine whether the grains in the annealed film grow from seed grains (grains which survived the implant). Crystallization of a silicon film self-implanted at a dose of  $2 \times 10^{15}$  ions/cm<sup>2</sup> due to the nucleation of crystallites and not due to the growth of grains that survived the implant. The nucleation rate was more than three orders of magnitude faster than that for either amorphous silicon or polycrystalline silicon self-implanted at  $5 \times 10^{15}$  ions/cm<sup>2</sup>. (Edited author abstract) 16 refs.

**095024 PROPERTIES OF DIFFUSED RESISTORS IN SOLAR-GRADE SEMICRYSTALLINE SILICON.** The transport properties of diffused p<sup>+</sup>-layers in n-type semicrystalline solar-grade silicon have been examined. It has been found that the grain boundary slightly increases the resistance of the majority carrier flow. A simple method is proposed to determine the average grain size, the barrier height and the effective trapping density at the grain boundary. Resistors made of these diffused layers show anomalous behavior concerning their voltage and temperature dependence. This anomaly is caused by the soft I-V characteristics of the isolation p-n junction. (Author abstract) 13 refs.

#### Cutting

**095025 WAFER SLICING BY INTERNAL DIAMETER SAWING.** Internal Diameter Sawing (IDS) is the commonly used technique for slicing hard and brittle materials such as semiconductive silicon and germanium or ceramics and glasses. Nevertheless, productivity and yield are relatively low on account of difficulty in handling the flexible tool. Increasing workpiece dimensions leads to greater problems in realizing quality requirements, such as high flatness, low roughness, and low crystal damage. This paper deals with basic relationships in IDS, applying to all workpiece materials. (Edited author abstract) 10 refs.

**095027 NITROGEN RELATED DONORS IN SILICON.** Electrical characteristics of identified N-related defects in Si are investigated by conductivity and Hall effect measurements. Results are presented for N-ion implanted layers which were annealed to introduce off-center substitutional N, N-N pair centers, and N aggregates. Neither off-center substitutional N nor the more predominant N-N pair center introduces the shallow donor activity previously reported for N-implanted Si. Shallow donor activity is observed, however, after annealing for 1h at 800°C and is attributed to N aggregates. The donor concentration increases rapidly with dose between  $2 \times 10^{14}$  and  $10^{15}$  cm<sup>-2</sup> (N concentrations  $\approx 1.5 \times 10^{19}$  cm<sup>-3</sup>), and then decreases at higher doses. (Edited author abstract) 16 refs.

**095028 INFLUENCE OF CARBON CONTENT ON INTRINSIC GETTERING PROCESS.** The authors studied the influence of carbon on oxygen precipitation and defect formation in P type CZ silicon. During the oxygen intrinsic gettering (IG) process, it was found that IG defects were fewer for wafers with carbon content up to  $1 \times 10^{17}$ /cm<sup>3</sup> although the precipitation rate of oxygen at 750°C was higher for the same samples. During the heat treatment at 750°C, the wafers with high carbon content appear to precipitate oxygen and carbon simultaneously and to create new donors. The thermal donors created at 450°C are the heterogeneous nucleation sites of IG defects. (Edited author abstract) In Chinese. 19 refs.

**095029 BASIC TYPES OF NONUNIFORMITIES AND THEIR MANIFESTATION IN THE GALVANOMAGNETIC PROPERTIES OF ESPECIALLY PURE SILICON.** A method is proposed for analyzing the type of nonuniformities in a single-crystalline pure material based on the changes in the 'asymmetry resistances,' determined from the magnitudes of the external potentials on the Hall contacts, in a magnetic field. By comparing their magnetic-field dependences with the analogous dependences of the Hall constant and of the resistivity, measured with different polarities of the voltage applied to the sample, it is shown that the asymmetry resistances are the parameters which are most sensitive to nonuniformity. It was found that nonuniformities of the 'compensation' type, i.e., space-charge regions in which the minority carriers make an appreciable contribution to the Hall constant, are systematically manifested in crystals of especially pure high-resistance silicon. The effective Hall factors were calculated under the conditions of Hall bipolarity of the impurity conductivity and the results are compared with the experimental data. (Author abstract) 13 refs.

**095030 SYSTEMATIC ANALYSIS OF DEFECTS IN ION-IMPLANTED SILICON.** A classification scheme for the different forms of implant-related damage which arise upon annealing consisting of five categories is presented. Category I damage is 'subthreshold' damage or that which results prior to the formation of an amorphous layer. If the dose is increased sufficiently to result in the formation of an amorphous layer then the defects which form beyond the amorphous/crystalline (a/c) interface are classified as category II ('end of range') damage. Category III defects are associated with the solid phase epitaxial

growth of the amorphous layer. It is possible to produce a buried amorphous layer upon implantation. If this occurs, then the defects which form when the two a/c interfaces meet are termed category IV ('clamshell', 'zipper') defects. Finally, category V defects arise from exceeding the solid solubility of the implanted species in the substrate at the annealing temperature. In addition to presenting examples of this classification scheme, new results emphasizing category II, IV, and V defects are presented. (Edited author abstract) 137 refs.

**095032 NEW PHOTOLUMINESCENCE DEFECT SPECTRA IN SILICON IRRADIATED AT 100 K: OBSERVATION OF INTERSTITIAL CARBON.** We report photoluminescence spectra of defects in irradiated silicon which are stable below room temperature. No-phonon lines (ST1)<sup>0</sup> at approx. 856 meV, ST2 at approx. 1115 meV, and ST3 at approx. 1126 meV are observed, along with a broad emission band extending from 0.7 to 1 eV. The ST1 defect studies is a deep hole trap at approx. E<sub>v</sub> + 0.25 eV, which, in addition, can bind an electron loosely. Piezospectroscopy shows that the defect is essentially <100> axial symmetric with slight distortion to C<sub>1h</sub>. The absence of Zeeman splittings confirms the deep hole binding in an axially symmetric potential. The independence of dopants, the annealing behavior, and comparison to EPR and IR active defects suggest a correlation of the ST1 defect with interstitial carbon. (Edited author abstract) 18 refs.

**095033 EPR STUDY ON A NEW TRICLINIC SYMMETRY DEFECT IN NEUTRON-IRRADIATED FZ-SILICON.** A new defect, labeled as Si-PK1, has been observed with EPR (Electron Paramagnetic Resonance) in neutron irradiated FZ-Si grown in argon, hydrogen and vacuum. Its symmetry has been determined to be triclinic symmetry, the lowest possible symmetry. Si-PK1 has not been observed in CZ-Si. It is not related to any common impurities in Si, like oxygen, carbon, phosphorus and boron. It is claimed to be an intrinsic defect. Combining with the empirical classification of g tensor, it is concluded that Si-PK1 may be a multivacancy cluster. (Edited author abstract) 14 refs.

**095036 CLUSTERS OF RADIATION DEFECTS IN SILICON WITH DISLOCATIONS.** The influence of dislocations ( $N_D = 1 \times 10^4$  to  $1 \times 10^7 \text{ cm}^{-2}$ ) on the radiation defect cluster formation by 640 mev proton irradiation was investigated in n-type silicon. The temperature dependences of Hall coefficient and conductivity obtained in the temperature interval of 80 to 400 K demonstrate that the production rate and thermal ionization energy of divacancies as well as the potential barrier for their aggregation are independent on the dislocation density  $N_D$ . In the case of A-centers these parameters appear to vary with  $N_D$ . Dislocation strain fields affect the formation of complexes of primary defect-impurity atom-type which are accumulated near the dislocations and create the impurity-defect atmosphere. The strain fields do not alter the processes of intrinsic defect cluster formation which occur in the region of the primary displacement cascade. (Edited author abstract) 6 refs.

**095037 NATURE OF LATTICE DEFECTS INDUCED BY EXCIMER LASER IRRADIATION FOR EXTRINSIC GETTERING.** Structure and thermal behavior of lattice defects in silicon induced by excimer laser irradiation, which is expected to be adopted as a new extrinsic gettering technique, were examined by transmission electron microscopy. Stacking fault tetrahedra and a peculiar type of dislocations which appeared in a V-shape were found in a melted and regrown layer of an as-irradiated sample. After subsequent heat treatment, slip dislocations were generated from the traces of laser beam shot and the stacking fault tetrahedra were mostly transformed into the V-shaped dislocations. These V-shaped dislocations were proved to be thermally stable and were expected to work as effective extrinsic gettering centers. (Author abstract) 13 refs.

**095038 THERMAL GENERATION OF FRENKEL PAIR IN SILICON.** A basic concept in thermodynamics states that, if an isolated system is left standing, it comes eventually to a final state which does not change. This final state is called the thermal equilibrium state. If vacancies and self-interstitials coexist, it is sure that they recombine with each other. Greatest importance is given to the basic concept in the thermodynamics mentioned above. Therefore, regardless of whether or not the thermal generation of the Frenkel pair is energetically possible, the Frenkel pair should be generated thermally as a reverse reaction of the recombination, to get the thermal equilibrium state. (Author abstract) 13 refs.

**095039 DEFECT PROPERTIES IN SILICON INDUCED BY RF PLASMA IRRADIATION.** The effects of rf room temperature air plasma irradiation on Si surface have been studied by the C-V and DLTS measurements. It is found that a thin oxide film is formed on the Si surface by the air plasma anodization. The DLTS measurements show a continuously distributed interface state and a single energy level at  $E_C - E_B = 0.54$  eV which is a kind of localized defect existed in the oxide layer near the interface. In addition, there are two energy levels in the bulk Si induced by the plasma interaction. They behave as the divacancy usually observed in the electron beam irradiated Si. The cross section of these defect levels are measured and their isochronal annealing behaviours have been investigated. (Author abstract) 7 refs.

**095041 THEORETICAL STUDIES OF THE NATURE OF 2210  $\text{cm}^{-1}$  IR ABSORPTION PEAK IN SILICON CRYSTAL CONTAINING HYDROGEN (I): VALENCE FORCE FIELD CALCULATIONS OF THE OSCILLATOR FREQUENCIES.** Starting from the idea of the Urey-Bradley force field, the authors have calculated the vibrational frequencies with a valence force field method for two models of the defect complexes corresponding to the 2210  $\text{cm}^{-1}$  peak in a silicon crystal containing hydrogen, vacancy + 4H and interstitial silane. Based on analysis of the calculated results and reasonableness of the force constant adjustments, it is concluded that the vacancy + 4H model is preferable. In addition, a reliable method is described in which the two models can be discriminated between experimentally. (Edited author abstract) 25 refs.

Guoren, Bai (Acad Sinica, China); Jiankun, Zhou; Jianmin, Chen; Tianshen, Shi; Mingwei, Qi; Leiming, Xie. *Sci Sin Ser A* v 31 n 4 Apr 1988 p 499-512.

**095042 NEW EPR DEFECT IN NEUTRON-IRRADIATED FZ-SILICON AND HYDROGEN PASSIVATION EFFECT.** A new EPR center having  $C_{2v}$  symmetry and  $S=1$ , labeled as Si-Pk3, has been observed for the first time in neutron-irradiated silicon. The spectra start to appear after a 150°C annealing and disappear at 500°C. The principal values of tensor g and D are determined. The microscopic model is proposed to be a trivacancy chain along the direction with an oxygen atom situated in the middle. The annealing temperature in hydrogen-containing samples is at least 150°C lower than that of other samples. (Author abstract) 15 refs.

Shuxiang, Wu (Peking Univ, China); Maoxun, Yan; Huiying, Xu; Jinchang, Mao; En, Wu. *Sci Sin Ser A* v 31 n 1 Jan 1988 p 98-104.

**095043 INVESTIGATION OF RADIATION DEFECTS IN HYPERABRUPT p-n JUNCTIONS.** Distribution profiles for the levels of radiation defects in hyperabrupt implanted p-n junctions irradiated by electrons with a dose up to  $5 \times 10^{15} \text{ cm}^{-2}$  were studied using admittance spectroscopy (AS). Besides a general tendency of the defect density to decrease towards the surface, the distribution of defects is correlated with the profile of the doping impurity (phosphorus). It is associated with the reduced energy of defect formation in the

layer implanted. The effect is measured of an electric field ranging within  $\epsilon \approx 10^4$  to  $5 \times 10^5 \text{ V/cm}$  on the activation energy for the emission rate of electrons from A- and E-centers. (Edited author abstract). 24 Refs.

**095044 DEFECT GENERATION AND GETTING DURING RAPID THERMAL ANNEALING.** The generation of crystallographic defects induced by metallic impurities diffusing from the back side of silicon wafers is observed during rapid thermal annealing. The type of defect generated depends on both the type and concentration of metal used. Saucer-pits, hillocks, and oxidation induced stacking faults are observed after oxidation in the time range 40-180s. These defects can be annihilated by gettering with a heavily doped P layer diffused into the back side of the wafers. The effectiveness of this annihilation depends upon the order of the gettering and defect-generating processes. It also depends on the type and concentration of metal used. (Author abstract). 56 Refs.

**095045 ROD-LIKE DEFECTS IN SILICON: COESITE OR HEXAGONAL SILICON?** The crystallographic nature of rod-like defects in silicon, as observed by high resolution electron microscopy after low temperature annealings of high oxygen content Czochralski silicon, ion implantation, or electron irradiation is discussed. The interpretation of the HREM images of the rod-like defects is critically examined in view of the two models recently proposed in the literature, i.e., hexagonal silicon or coesite  $\text{SiO}_2$  precipitates. It is shown that the interpretation as hexagonal silicon instead of coesite precipitates is very favourable. (Author abstract). 33 Refs.

Bender, H.; Vanhellemont. *Phys Status Solidi A* v 107 n 2 Jun 1988 p 455-467.

**095046 PROS AND CONS FOR DANGLING BONDS AT DISLOCATION CORES IN SI.** Some peculiar results of deep-level transient spectroscopy (DLTS) measurements on plastically deformed hydrogenated Si are explained in terms of a model for the driven reconstruction of dislocations. Driven reconstruction may be responsible for the reduction in the density of high-temperature electron paramagnetic resonance (EPR) centres after predeformation and after deformation during heat treatment in a hydrogen atmosphere. The model for driven reconstruction is based on the assumption that the non-reconstructed state is the lowest energy state of the dislocation core. Together with numerous results concerning electrical conduction along dislocation cores, the considerations presented in this Letter strongly indicate that dangling bonds exist within dislocation cores in Si. The absence of a dislocation-related EPR signal suggests that there must be a reason, intrinsic to the dislocation core, by which dangling bonds in dislocations do not carry unpaired electrons. (Author abstract). 13 Refs.

**095047 DEFECT ENGINEERING FOR VLSI EPITAXIAL SILICON.** The control of dopants, impurities and defects for very large scale integration of silicon integrated circuits requires a complex set of crystal and processing conditions to be satisfied simultaneously. In order to achieve the maximum yield and highest level of electrical performance for a given device design, we have manipulated the lattice constant and boron doping levels in CVD epitaxial silicon layers co-doped with germanium. By adjusting the ratios of germane and diborane in a dichlorosilane/hydrogen CVD reactor we can achieve extrinsic gettering using controlled introduction of interfacial misfit dislocations with Si(Ge), and buried high conducting layers which are strain-free and lattice

matched to the Si substrate. A variety of these structures have been characterized using gated-diode leakage, spreading resistance profiling, MOS lifetime, cross-sectional TEM, SEM-EBIC and SIMS depth profiling. (Author abstract) 16 refs.

**095053 CALCULATION OF BOUND ELECTRON STATES AT RECONSTRUCTED 90° PARTIAL DISLOCATIONS IN SILICON BY LCAO METHODS IN THE FOUR COORDINATION-SPHERE APPROXIMATION.** A theoretical study is made on bound electron states in dislocations in Si. The bound states are calculated by a recursion form of the strong-coupling method, which also employs the translational symmetry along a dislocation line. (Author abstract) 11 refs.

Teichler, H.; Marheine, C. *Bull Acad Sci USSR Phys Ser* v 51 n 4 1987, Proc of the Fifth Int Conf on the Prop and Struct of Dislocat in Semicond, Moscow, USSR, Mar 17-22 1986 p 34-38.

**095054 OPTICAL NUCLEAR-MOMENT POLARIZATION IN PLASTICALLY STRAINED SILICON SINGLE CRYSTALS.** In research on broken bonds in semiconductors, the following points must be borne in mind: 1) a broken bond is a complicated electron-vibrational system having several charge states and local multiplet spin correlation, 2) electron-electron correlations in each broken bond are responsible for producing the Mott-Hubbard insulator with narrow bands, and 3) the carrier mobility in the broken-bond system reflects the degree of strain disorder and the polaron effects, and it is dependent on the type of magnetic ordering in the chain on account of the spin correlations. 14 refs.

**095057 INDUCED-CURRENT STUDY OF DEFECTS IN STRAINED SILICON.** It has been found that the dislocation contrast increases with heat-treatment temperature, whereas the electrical activities determined from the Hall effect, DLTS, and thermally stimulated depolarization fall as the temperature and time of heat treatment increase. To elucidate the reasons for this conflict, we have examined how the EBIC contrast is dependent on defects produced by plastic strain, heat treatment, and impurity composition. The results are compared with those on the electrophysical properties of the same crystals obtained by other methods. 13 refs.

**095058 FORMATION KINETICS AND BEHAV-**

**IOR FOR NONLINEAR EXCITATIONS LIMITING DISLOCATION MOBILITY IN SEMICONDUCTOR SINGLE CRYSTALS.** The experiments were performed with n-type silicon specimens cut from dislocation-free crystals grown by crucible-free zone melting and doped during growth with phosphorus to a resistivity of 1.5  $\Omega$ -m. The specimens were rectangular prisms having edge orientation of dimensions 35×4×1.5 mm. Individual dislocations were introduced from a scratch and detected by selective chemical etching. We examined three types of dislocation on the compression side: screw ones and two types of 60° dislocation with opposite sequences for the partial ones. We considered only dislocations not having subsurface kinks. 12 refs.

**095066 PROBLEMS IN INTERPRETING SILICON EBIC MEASUREMENTS.** Problems are discussed in determining recombination parameters from EBIC diffusion-length and measurements. Results on the electrical parameters of defects are discussed in relation to impurity doping and temperature effects. (Author abstract) 33 refs.

Kittler, M.; Seifert, W.; Richter, H. *Bull Acad Sci USSR Phys Ser* v 51 n 9 1987, Proc of the Fifth Int Conf on the Struct and Prop of Dislocat in Semicond, Moscow, USSR, Mar 17-22 1986 p 82-88.

**095067 PLASMA EFFECTS ON EBIC SIGNALS FROM SILICON.** The maximal plasma losses and the maximum contrast at dislocations occur at almost the same bias, and they give similar graphs as functions of beam current, so the different parts on the contrast-bias curve are ascribed to differences in recombination at defects: within the depleted layer, under the depleted layer, and within the neutral plasma during drift and diffusion. The lower limit to the bias  $V_1$  is ascribed to the plasma dimensions approaching the Debye length, while the upper limit  $V_h$  agrees qualitatively with predictions from a plasma erosion model, i.e., the value of  $V_h$  is linearly related to the beam current. 7 refs.

## Diffusion

**095072 NEW MODEL FOR THE DETERMINATION OF POINT DEFECT EQUILIBRIUM CONCENTRATIONS IN SILICON.** In this paper the boundary conditions for point defect distributions in monocrystalline silicon are investigated. These boundary conditions are established by simple thermodynamic considerations. A circle process is used including vacancy, interstitial and Frenkel pair generation which yields a simple relationship between the vacancy and interstitial equilibrium concentrations at the surface. A new OED model is also presented which explains the  $t^{-1/4}$  behavior for the interstitial supersaturation. This model is used to simulate experiments of Mizuo and Higuchi. In this way values for the equilibrium concentrations and the diffusion coefficients of vacancies and interstitials are obtained. (Author abstract) 9 refs.

**095073 INFLUENCE OF NUCLEATION ON THE KINETICS OF BORON PRECIPITATION IN SILICON.** A study of the precipitation of boron implanted into pre-amorphized silicon has been carried out following several thermal processes in the temperature range between 550 and 900°C. It will be shown that the formation of inactive boron takes place even during a low-temperature solid-phase epitaxy of the regrowing layer, when the starting concentration level exceeds about  $3.5 \times 10^{20}$  atoms/cm<sup>3</sup>. The presence, at the beginning of the annealing process, of inactive atoms in the form of small aggregates which behave as nucleation centers, markedly affects the precipitation kinetics during the thermal treatments. In these conditions the experimental data follow F.S. Ham's theory of precipitation. On the contrary, if all the dopant is incorporated in the lattice side, nucleation is the limiting factor for boron deactivation. (Author abstract) 30 refs.

**095074 ODMR STUDIES ON NEW DONORS IN SILICON.** The ODMR (Optically Detected Magnetic Resonance) studies of the characteristic spectral line K (0.902eV) of ND (new donors) in Si show that the corresponding luminescence center is a neutral isoelectronic trap and the luminescence transition is the radiative recombination of bound excitons of the trap. An isotropic  $g_R = 1.997 \pm 0.001$  band is observed, which implies a hole-attractive local potential of the center. The result supports the author's previous suggestion about the luminescent mechanism of line K. (Author abstract) In Chinese. 9 refs.

**095075 VAPOUR-PHASE DIFFUSION OF ALUMINIUM INTO SILICON.** The purpose of this letter is to report a study of experimental conditions which can affect the aluminium surface concentration in silicon throughout the vapor-phase diffusion cycle. The present investigations were carried out for different experimental conditions under which the aluminium surface concentration remains effective throughout the diffusion cycle. The present results show that the source temperature must be optimized around 1025°C, under a vacuum of  $10^{-6}$  torr. Above 1030°C, the surface concentration begins to decrease as the aluminium source temperature increases. This unexpected observation can be attributed to a decrease of the partial pressure of the aluminium vapor due to the vapor oxidation by the residual water vapor and oxygen in the system. Higher diffusion temperatures (above 1150°C) yield lower surface concentrations which are partly due to the increase of the aluminium vapor oxidation, and moreover, can create a reproducibility problem. 10 refs.

**095076 VARIATION OF Sb CONCENTRATION IN MELT DURING THE GROWTH OF HEAVILY Sb-DOPED Si SINGLE CRYSTALS.** A mathematical model has been established for characteristics of the variation of Sb concentration in the melt during the growth process of heavily Sb-doped Si single crystals. The calculated curve drawn with the model is in good agreement with the experimental one. As a result of the segregation of the solute during pulling, the concentration of Sb in the melt increases. It is found from the calculated curves that the increase of Sb concentration can be brought under control while the pulling process was carried out under a reduced pressure. Thus, the formation of a cellular interface could be postponed. As the pressure

in a furnace decreases to 2.7 kPa, the Sb concentration will be kept almost unchanged. (Edited author abstract) 8 refs. In Chinese.

**095082 INVESTIGATION OF THE MAJORITY CARRIERS DIFFUSION COEFFICIENTS BEHAVIORAL PATTERN IN DEGENERATELY-DOPED SILICON.** For electron and hole concentrations equal to or larger than the corresponding density of states in the conduction and valence bands, the ratio of the majority carriers diffusion coefficient-to-drift mobility increases with the power of (2/3) of the corresponding majority carriers concentration. It is shown that the majority carriers diffusion coefficient in degenerately-doped silicon increases sharply with the dopant level in the  $10^{19}$  to  $5 \times 10^{21}$  cm<sup>-3</sup> range of the latter, regardless of the ambient temperature. Exact values of diffusion coefficients in phosphorus-, arsenic- and boron-doped silicon are presented up to carrier densities one order of magnitude higher than the solid solubility. Implications of the presented results for the physics of silicon-based electron devices are also outlined. (Edited author abstract) 16 refs.

**095085 LOWER LIMIT OF DETECTABILITY AT HIGH SPATIAL RESOLUTION OF As IMPLANTED INTO Si USING THE JEOL 200CX IN THE STEM-EDX MODE.** The objective of this study is to determine the accuracy and detectability of STEM X-ray dopant profiling using a conventional W-filament-equipped, general-user instrument by direct comparison of the STEM profile with that determined by both Rutherford backscattering (RBS) and secondary ion mass spectroscopy (SIMS). To this end, therefore, a Si wafer was implanted at 100 keV,  $5 \times 10^{15}$  cm<sup>-2</sup> with As and was made into both a cross-sectional TEM specimen and planar, approximately 1 cm<sup>2</sup> RBS and SIMS specimens. Difficulties of STEM-EDX dopant profiling arise from drift, contamination, beam size, beam spreading within the sample, specimen damage, and diffraction effects. For each factor we have described a method of compensation in the JEOL 200CX case. 30 refs.

Renteln, P. (Cornell Univ, Ithaca, NY, USA); Ast, D.G. *Ultramicroscopy* v 24 n 1 1988 p 37-44.

**095086 CONTROLLED ATOMIC LAYER DOPING AND ALD MOSFET FABRICATION IN Si.** Controlled atomic layer doping (ALD) is obtained, combining the adsorption and desorption behaviors of Sb in Si molecular beam epitaxy and solid phase epitaxy. SIMS and C-V measurements confirm the sharp doping profile. It is shown by Hall measurements that the carrier concentration varies from  $9 \times 10^{11}$  to  $8 \times 10^{13}$  cm<sup>-2</sup> and

the mobility from 250 to 60 cm<sup>2</sup>V<sup>-1</sup>s<sup>-1</sup> when the Sb concentration is changed from 0.0015 to 1 monolayer. The first ALD-MOSFET, with a gate length of 8 μm and a gate oxide thickness of 100 nm, is made using the ALD layer as the conducting channel, and has a transconductance of 7 mS/mm. (Author abstract) 14 refs.

**095087 OXYGEN-DOPED Si EPITAXIAL FILM (OXSEF).** We propose a new wide-gap material, an oxygen-doped Si epitaxial film (OXSEF), for applications to Si heterobipolar transistors (HBTs). OXSEF containing several tens of at.% of oxygen can be grown on a Si substrate by depositing Si in about  $10^{-6}$  Torr O<sub>2</sub>. OXSEF is literally almost a single crystal with an identical crystalline structure to Si, although it includes {111} twins as defects caused by oxygen. Temperature and O<sub>2</sub> pressure dependences of oxygen concentration in OXSEF are dominated by oxygen adsorption on the Si surface. Oxygen atoms in OXSEF segregate to some extent to form incomplete oxides like SiO<sub>1.5</sub>, but complete phase separation as a mixture of Si and SiO<sub>2</sub> regions does not occur, probably because of non-equilibrium conditions in MBE growth. Valence band discontinuity at the Si/OXSEF interface is deduced to be 0.26 eV based on photoelectrical measurements. (Author abstract) 23 refs.

**095088 DOPING OF POLYSILANE ALLOYS.** In order to control the conductivity of plasma-prepared wide-optical-gap binary Si:H alloys containing a number of (SiH<sub>2</sub>)<sub>n</sub> groups (polysilane alloys), boron and phosphorus doping are performed using pre-mixed Si<sub>2</sub>H<sub>6</sub>+B<sub>2</sub>H<sub>6</sub> and Si<sub>2</sub>H<sub>6</sub>+PH<sub>3</sub> gases. The conductivity can be controlled by about nine and six orders of magnitude for p and n type alloys, respectively, even when prepared at 300 K. The low substrate temperature of 300 K provides the condition suitable for forming linear-chained (SiH<sub>2</sub>)<sub>n</sub> groups, and all the doped alloys have wide optical gaps of greater than 2.0 eV due to the incorporation of (SiH<sub>2</sub>)<sub>n</sub>. The doping mechanism of the polysilane alloys is also discussed, and is compared with that of conventional hydrogenated amorphous silicon. (Author abstract) 7 refs.

**095090 PRESSURE DEPENDENCE OF THE DIAMAGNETIC SUSCEPTIBILITY OF SHALLOW DONORS IN SILICON.** A theory of the diamagnetic susceptibility ( $\chi_{dia}$ ) of a shallow donor in Si is given incorporating the many valley structure of the conduction band minimum. This theory is used for the computation of  $\chi_{dia}$  for various uniaxial stresses applied along [100], [110] and [111] directions. The effect of the uniaxial stress on the donor states is considered by following the valley repopulation model of Wilson and Feher. It is found that

the directional dependence is negligible and diamagnetism increases with the value of pressure. (Edited author abstract) 22 refs.

**095092 DSC STUDIES OF GLASSY BEHAVIOR IN P-DOPED a-Si:H.** Differential scanning calorimetry (DSC) studies of P-doped hydrogenated amorphous silicon (a-Si:H) show characteristic behaviors of glass transition phenomena as frequently found in conventional melt-quenched glasses. The glass transition temperature ( $T_g$ ) detected by DSC agrees well with the equilibration temperature ( $T_E$ ) determined by the temperature dependence of dc conductivity. Regarding the influence of hydrogen content,  $T_g$  decreases as hydrogen content increases. (Author abstract) 6 refs.

**095093 PHOSPHORUS DOPING INTO SILICON USING ArF EXCIMER LASER.** In this work we perform impurity doping using ArF excimer laser with a doping gas that is absorbed at 193 nm, and investigate the influence of photochemical decomposition on doping characteristics. Since we compare doping in gas ambients with that using only the adsorbed layers at the same laser wavelength, we are able to separate the effect that photochemical decomposition of a doping gas has on dopant incorporation. From the experiments of doping in  $\text{POCl}_3$  ambients and that using the adsorbed layers formed on the silicon surface, it is shown that dopant atoms produced by photochemical decomposition of  $\text{POCl}_3$  influence the doping characteristics. The surface concentration of carrier concentration profiles in doping using  $\text{POCl}_3$  adsorbed layers increases with the number of pulses, indicating that the supply of dopant atoms from the adsorbed layers to the silicon surface is rate limiting. 15 refs.

**095094 DETERMINATION OF Pt-GROUP METAL DOPANTS IN SILICON BY GRAPHITE FURNACE ATOMIC ABSORPTION SPECTROMETRY.** Pt-group metal determinations were investigated. The sensitivities (1% absorption) were  $5.8 \times 10^{-11}$ ,  $2.8 \times 10^{-11}$ ,  $2.6 \times 10^{-11}$ ,  $2.8 \times 10^{-10}$  and  $1.8 \times 10^{-10}$  g for Ru, Rh, Pd, Ir, and Pt, respectively. Around these sensitivities, the relative standard deviation for each element were not more than 9%. The method developed is sensitive and accurate, so it is suitable for the analysis of traces of Pt-group metal dopants in microsamples of Si. (Author abstract) 7 refs. In Chinese.

**095095 SURFACE DOPING OF SEMICONDUCTORS BY PULSED-LASER IRRADIATION IN REACTIVE ATMOSPHERE.** Intense pulsed-laser irradiation in a suitable chemical atmosphere can produce a significant incorporation of chemical species from the environment to the surface molten layer. This process has been used to produce p-n junctions in silicon and GaAs

irradiated, respectively, in  $\text{PCl}_3$  and  $\text{SiH}_4$  atmospheres. A modeling of the incorporation process, taking into account the solid-liquid-solid transition of the surface layer, has been developed following both a numerical and a semi-analytical approach. The modeling of the doping process gives results in a reasonably good agreement with the experimental doping profiles, obtained by irradiating Si samples in  $\text{PCl}_3$  atmosphere. (Author abstract) 22 refs.

**095096 EFFECT OF DOPING ON THE BEHAVIOR OF MICRODEFECTS IN DISLOCATION-FREE SILICON.** The concentration of metallographically revealed microdefects in highly doped samples in the initial state is, on the average, an order of magnitude less than in weakly doped samples. Regardless of the type and concentration of doping element, after heat treatment the microdefects create displacement fields corresponding to defects with a specific atomic volume greater than that of the matrix. The doping of silicon with various impurities (B, As, Sb, Ge) causes the process of microdefect development to be slowed down. The size of microdefects in highly doped samples, all other conditions being equal, in 2 to 3 times less than in weakly doped samples. The introduction of a doping impurity in amounts no less than  $5 \cdot 10^{18} \text{ cm}^{-3}$  leads to a slowing down of the development of growth-type microdefects. 9 refs. In Russian.

**095097 NITROGEN DOPING IN HYDROGENATED AMORPHOUS SILICON.** A direct evidence of substitutional doping in ion beam deposited amorphous hydrogenated silicon by nitrogen is presented. From the analysis of infrared (IR) absorption spectra and Si-2p core level shape, measured with X-ray photoelectron spectroscopy (XPS), the preferential tendency of nitrogen to go in for three-fold coordination at higher concentration and tetrahedral bonding at lower concentration ( $\leq 4 \text{ at}\%$ ) is established. XPS technique has been used for the first time to deduce the upper limit for substitutional solid solubility of the impurity. (Author abstract) 18 refs.

**095098 ROLE OF HYDROGEN IN DOPING MECHANISM FOR a-Si:H ALLOYS.** Calculations of electronic energies for structural clusters simulating phosphorus and boron substitutional doped and undoped pure and hydrogenated silicon have been performed using CNDO/2 quantum chemical molecular orbital method. The results show that more energy for implanting impurities is required in hydrogenated Si cluster than that in pure Si cluster, and a band of shallow gap states is induced by the substitutional doping in the hydrogenated system. From the results, it is concluded that the hydrogenation is a key factor of efficient substitutional doping in the a-Si:H alloys. (Edited author abstract) 9 refs.

**095099 CHEMICALLY INDUCED GRAIN BOUNDARY MIGRATION IN DOPED POLYCRYSTALLINE SILICON FILMS.** Chemically induced grain-boundary migration is demonstrated in polycrystalline silicon films. Growth of anomalously large grains, along with dopant depletion, is observed in P-doped polycrystalline Si films annealed at  $700^\circ\text{C}$  in the presence of a neighboring  $\text{TiSi}_2$  film. We propose a novel driving mechanism for migration, an electrostatic force on the interface due to inhomogeneous dopant depletion. (Edited author abstract) 17 refs.

**095101 EFFECT OF INHOMOGENEOUS DOPANT PROFILES ON THE ELECTRON ENERGY LOSS SPECTRA OF Si(100).** Surface plasmon excitations are measured by high resolution electron energy loss spectroscopy (HREELS) on highly n-doped, clean Si(100) wafers. After different annealing cycles at  $900^\circ\text{C}$  the plasmon loss shifts to lower loss energy. This effect can be quantitatively described by out-diffusion of the phosphorus dopant. The assumption of diffusion profiles and fits of calculated loss spectra to the experimental data allow a determination of the diffusion constant of phosphorus in silicon. (Author abstract). 9 Refs.

Foerster, A. (RWTH, Aachen, West Ger); Layet, J.M.; Lueht, H. *Appl Phys A* v 47 n 1 Sep 1988 p 95-97.

**095102 EXPERIMENTAL EVIDENCE FOR BORON-HYDROGEN INTERACTION IN BORON-DOPED SILICON PASSIVATED WITH HYDROGEN.** The infrared absorption of silicon implanted with  $^{10}\text{B}$  and  $^{11}\text{B}$  isotopes passivated with  $^1\text{H}$  or  $^2\text{H}$  reveals a boron-related shift of the H vibrational line associated with the passivating complex. The small shift observed for  $^1\text{H}$  is expected from a model of bond-centered hydrogen interacting weakly with boron. The boron shift for  $^2\text{H}$  is 4 times larger. This can be explained qualitatively by assuming that there are two equilibrium positions for hydrogen in the hydrogen bond between Si and B and that the relative energy minima are not the same for  $^1\text{H}$  and  $^2\text{H}$ . (Author abstract). 20 Refs.

**095103 EFFECT OF DOPING DENSITY AND INJECTION LEVEL ON MINORITY-CARRIER LIFETIME AS APPLIED TO BIFACIAL DENDRITIC WEB SILICON SOLAR CELLS.** The measured short-circuit current density in bifacial dendritic web silicon solar cells has been found to decrease with decreasing base resistivity, particularly under back illumination. In addition, the ratio of short-circuit current under back illumination to short-circuit current under front illumination was observed to vary with light intensity. These observations reflect the fact that the minority-carrier lifetime in the base of these cells is a function of the base resistivity and the illumination level. The dopant was assumed to play only an indirect role in determining lifetime. This decrease in lifetime is shown to follow from a distribution of defect levels in the bandgap. These levels are a consequence of extended defects that have been observed in the web material. The dopant, acts only in the indirect role of moving the Fermi level over an existing background distribution of defect levels that arise from the extended defects. Assuming a parabolic distribution of defect levels in the bandgap, the minority-carrier lifetime was calculated as a function of doping density and excess carrier concentration (illumination level) using the Shockley-Read-Hall theory. The short-circuit current densities

that were calculated using these lifetimes agreed reasonably well with measured values for bifacial dendritic web silicon solar cells 26 refs.

**095104 IMPROVED MEASUREMENTS OF DOPING PROFILES IN SILICON USING CV TECHNIQUES.** One of the problems of doping profile measurements using CV techniques is that numerical differentiation is required. This can, under certain circumstances, result in very noisy profiles. A method is presented for obtaining noise-free profiles by choosing a step size that takes account of the resolution of the capacitance meter to ensure that the maximum profile detail is retained. A range of other factors that can affect profiling accuracy are also reviewed. 19 refs.

**095108 HEAVY DOPING EFFECTS IN SILICON.** Different mechanisms causing bandgap narrowing in heavily doped silicon are reviewed. A distinction is made between many-body effects and the effects due to random impurity distribution. The values of bandgap narrowing, calculated using a theoretical model, are compared with the experimental results. Recombination in heavily-doped silicon is discussed and the different recombination mechanisms, present at high doping levels, are explained.

Experimental values for the minority-carrier lifetime as a function of the doping level are given. Surface recombination at the heavily doped Si/SiO<sub>2</sub> interface is discussed, the transport equations in the case of a position dependent bandgap are derived, and the influence of heavy-doping effects on the performance of several devices is discussed. **095109 OPTICAL CHARACTERIZATION OF HEAVILY DOPED SILICON.** Out of a variety of optical techniques used to characterize heavily doped semiconductors photoluminescence and Raman spectroscopy are discussed as tools to study heavy doping effects. Photoluminescence spectroscopy is sensitive to electronic transitions between the conduction and valence band whereas electronic Raman scattering probes transitions within either band. Parameters relevant to device physics such as the band gap shrinkage due to heavy doping are extracted from these measurements. It is shown that both techniques are applicable to the characterization of thin heavily doped implanted or epitaxial layers. (Edited author abstract) 28 refs.

**095111 ELECTRICAL DOPING PROFILES ON TEXTURIZED SURFACES.** The texture etching on (100) Si surfaces produces an array of pyramids of 1-10  $\mu$ m base dimension. Texturized surfaces are used as wideband anti-reflection structures in Si solar cell technology. Doping techniques are then performed on the so obtained non-planar surfaces. For a complete characterization of solar cells it is important to measure the electrically active dopant concentration vs depth. To determine this profile, the authors used an automatic apparatus that combines differential Hall effect and resistivity measurement with anodic stripping of successive layers. This technique implies the knowledge of the angle between the vectors of carrier drift velocities and magnetic field in which the sample is placed. In texturized samples this angle is not constant. The aim of the work is to show the applicability of the technique on these kinds of samples. 2 refs.

**095114 MEYER-NELDEL RULE IN FIELD-EFFECT MEASUREMENTS AND THE MICROSCOPIC PREFACTOR OF THE CONDUCTIVITY IN a-Si:H.** The temperature dependence of the field-effect characteristic is studied. The data are analyzed on the basis of the effective density of states function obtained from the data at a single temperature. It is shown that there are four reasons for the Meyer-Neldel-like behavior: the statistical shift of the bulk Fermi-level, the temperature shift of the conduction band, the breakdown of the interface approximation, and as the most important effect the explicit temperature dependence of the Fermi distribution. The energetic position of the dominant transport path, the temperature coefficients of the Fermi level and of the conduction band energies are obtained by fitting the entire set of measurements. An analysis allows the determination of the microscopic prefactor of the flat-band conductivity. (Edited author abstract) 14 refs.

**095115 FIELD-EFFECT ANALYSIS FOR THE DETERMINATION OF GAP-STATE DENSITY AND FERMIL-LEVEL TEMPERATURE DEPENDENCE IN POLYCRYSTALLINE SILICON.** The field-effect conductance has been used in two distinct ways to determine the gap-state density in polycrystalline silicon. The relationship between the surface potential and the gate voltage, which determines the gap-state density, has been deduced according to the incremental method, already proposed by T. Suzuki et al., and a new method. The new method is based on the temperature dependence of the derivative of the field-effect conductance with respect to the gate voltage. The results from the two methods are in good agreement and show a rapidly increasing gap-state density in the upper half of the gap. The temperature analysis of the field-effect conductance indicates that the position of the Fermi level is temperature dependent. (Edited author abstract) 19 refs.

**095119 IMPACT IONIZATION AND ELECTRIC FIELD QUENCHING OF PHOTOLUMINESCENCE IN SILICON.** The photoluminescence intensity at 1.8 K of deep and shallow bound excitons, free excitons and electron-hole droplets in silicon is investigated in a weak electric field. The photoluminescence as well as the photocurrent was detected with simultaneous pulsed excitation of both laser light and electric field. The luminescence is quenched due to impact ionization by field accelerated hot electrons and holes starting around 50-100 V/cm for the shallow bound excitons, depending on sample purity and excitation intensity. The deeply bound excitons increase in intensity with applied field and are difficult to completely quench before the electrical breakdown of the sample. The impact ionization of the free excitons is sensitive to the presence of the electron-hole droplet phase. No significant difference between n- and p-type samples was observed. (Edited author abstract)

**095120 Si HETEROJUNCTION BIPOLAR TRANSISTORS WITH SINGLE-CRYSTALLINE  $\beta$ -SiC EMITTERS.** The electrical characteristics of single-crystalline  $\beta$ -SiC grown on a Si substrate and the SiC/Si heterojunction system have been investigated to determine their suitability for the application to heterojunction bipolar transistors. Arsenic and phosphorus ion implantation and subsequent furnace annealing were found to provide n-type SiC layers with the sheet resistivity of several hundred ohm/square. The current-voltage characteristics can be given as  $J = J_0 \exp(qV/nkT)$ , where the value of  $n$  is around 1.35. Heterojunction bipolar transistors using SiC as a wide-gap emitter were realized for the

first time and compared with previously reported Si-based HBT's. The performance of our wide-gap emitter becomes superior to others at large Gummel numbers. (Author abstract) 11 refs.

**095121 GENERATION LIFETIME IN HIGH RESISTIVITY SILICON.** The dark current at 295 K in some large area n+p diodes with gold base contacts has been analyzed to show the quality of the high resistivity wafers was generally very good. Estimates of the generation lifetime in the processed wafers ranged from 5 to 30 ms. The diffusion current injected at the base contact was often larger than the generation component and both were spatially variable. The behavior of the diffusion component implied a base contact interface generation velocity falling to values near  $10^4$  mm/s or lower in places. (Author abstract) 44 refs.

**095122 STUDY OF ELECTRICAL INSTABILITY IN DETECTOR-GRADE NTD SILICON.** Electrical measurements have been used to investigate air quenching effects. Some instabilities of electrical properties were observed over the temperature range  $450 \pm 50^\circ\text{C}$ , i.e., a conduction type conversion (n  $\rightarrow$  p) follows the gradual rise in resistivity as a function of the time after quenching. The experiments indicate that this is a property peculiar to mixed NTD silicon. A large effect can be noted in sample pre-annealed at  $650^\circ\text{C}$ . The instability is reversible and can remain at liquid nitrogen temperature for a long time. (Edited author abstract) 3 refs. In Chinese.

**095123 FREQUENCY-DEPENDENT PHOTOVOLTAGE-GENERATING AREAS IN A STRONGLY-INVERTED OXIDIZED p-TYPE SILICON WAFER.** Surface photovoltages (SPVs) excited with a chopped 632.8 nm-wavelength photon beam (PB) were measured with a transparent electrode that covered half of a sample wafer 76 mm in diameter. The PB diameter was kept at  $120 \mu\text{m}$  and the PB power at  $1 \mu\text{W}$ . Since the wafer resistivity was  $0.29 \Omega\text{m}$ , the wafer surface was considered to be strongly inverted after forming a dry oxide layer  $280 \text{ nm}$  thick. SPVs were observed by changing the PB-irradiating positions so that the beam both did and did not pass through the transparent electrode. When the PB-chopping frequency was as low as 2 Hz, the SPV appeared across the entire wafer surface. However, the SPV-generating area decreased around the PB-irradiated point as the frequency became high. This can be explained by a distributed resistance and capacitance network model, previously reported by others. (Author abstract) 19 refs.

**095124 MODEL FOR THE STAEBLER-WRONSKI EFFECT.** Based on experimental results of transient photoresponse and photo-induced reversible changes for the same a-Si:H pin-type solar cell structure, a model is proposed for the Staebler-Wronski effect, by which reversible changes of the photo-induced dangling-bond density can be interpreted. We show that the origin of the effect is a space-charge redistribution caused by the corresponding reversible changes of internal electric fields in a-Si:H. A discussion is given of the reversible transitions during illumination and annealing. (Edited author abstract) 11 refs.

**095125 VARIABLE-RANGE HOPPING AND THE HALL COEFFICIENT IN Si:As.** Conductivity and Hall measurements were made on Si:As samples on the barely-insulating side of the metal-insulator transition. Both conductivity and Hall coefficient obey variable-range hopping behavior ( $\ln \sigma \propto -(T_0/T)^{1/4}$  and  $\ln R_H \propto (T_0H/T)^{1/4}$ ), with the quantity  $(T_0H/T_0)^{1/4}$  equal to  $0.63 \pm 0.02$  in the limit of low magnetic field at the critical concentration,  $N_c$ . This is the first experimental verification of the theoretical predictions of Gruenewald et al. for  $R_H$  in the variable-range hopping regime.  $(T_0H/T_0)^{1/4}$  decreases somewhat with both increasing field and decreasing donor density. The prefactor for the Hall coefficient gives a value for  $\lim(1/NeR_H)$  as  $N \rightarrow N_c$  consistent with the corresponding results in this system on the metallic side of the transition. (Author abstract) 16 refs.

**095126 STRUCTURAL AND PHOTOELECTRICAL PROPERTIES OF A THIRD-ORDER TWIN BOUNDARY ( $\Sigma = 27$ ) IN SILICON.** In contrast to the joint the boundary displayed structural instability. On annealing it faceted and dissociated forming lower energy defects of twin boundaries of first and second orders. The  $\Sigma = 27$  boundary is of high electrical activity in the symmetrical  $\{552\}/\{552\}$  and faceted (parallel to the plane  $\{111\}$  of one of the grains) orientations. Surface recombination velocities ( $s$ ) equal  $6.6 \times 10^5$  and  $1.3 \times 10^6 \text{ cm s}^{-1}$  at 300 K, respectively. The value  $s$  increases approximately twice during faceting which agrees with geometrical models for the  $\Sigma = 27$  boundary in a diamond lattice. The electrical activity of the tetrajoints and the regions of the intersection of electrically inactive first order twin boundaries is revealed. (Edited author abstract) 16 refs.

**095127 DC AND AC CHARACTERIZATION OF GRAIN BOUNDARIES IN FLOAT ZONE SILICON.** A grain boundary (GB) in a float-zone (FZ) silicon bicrystal was studied by, current-voltage characteristics and admittance spectroscopy. For both methods a common model is used which takes into account potential fluctuations in the GB plane. A unique deconvolution scheme for the experimental data is presented. Within that model all measurements, dc and ac, over the whole temperature ( $200 \text{ K} \leq T \leq 300 \text{ K}$ ) and doping ( $5 \times 10^{12} \text{ cm}^{-3} \leq N_D \leq 10^{15} \text{ cm}^{-3}$ ) range studied can be described by a common density of states in the GB. Additionally, information about the inhomogeneity of the barrier height in the GB plane and traps in the space charge zone is obtained. (Author abstract) 13 refs.

**095129 NEW EXPERIMENTAL DETERMINATION OF THE RELATIONSHIP BETWEEN THE HALL MOBILITY AND THE HOLE CONCENTRATION IN HEAVILY DOPED p-TYPE SILICON.** The relationship between the Hall mobility and the hole concentration in p-type silicon were experimentally investigated. Boron and gallium were used as dopants; their doping was done by either the ion implantation or the diffusion technique. It was found that the relationships for boron-doped specimens and for gallium-doped specimens for the heavily doped range are considerably different from each other. Both of these relationships are also different from the so-called Irvin curve which is well known as a standard relationship between the mobility of carriers and the impurity concentration, but the relationship for boron doping is almost consistent with that of Thurber et al., if the Hall mobility factor is reasonably taken into account. **095130 KILOVOLT ELECTRON ENERGY LOSS DISTRIBUTION IN Si.** Using the electron-beam-induced barrier current and the Monte Carlo simulation it was possible to determine the depth-dose function as well as the distribution function of the generation source for electron-hole pairs perpendicular to the injection direction. The depth-dose function was compared with results obtained by Everhart and Hoff. By fitting the simulated barrier current profile to the measured one we could estimate the relatively small width of the space charge region of the p-n junction employed for the measurements. Furthermore, the spatial dose distribution of Si was described in an analytic approximation of the Monte Carlo simulation using two Gaussian functions concerned with the spreading of the penetrating electron beam and the diffusion of the primary electrons within the target, respectively. This approximation was based on treatments of the scattering process of the primary electrons given by Bethe and co-workers, Bothe and Archard. (Author abstract) 16 refs.

**095135 IN SITU WORK FUNCTION MEASUREMENTS IN EVAPORATED AMORPHOUS SILICON.** In situ contact potential difference measurements have been used to determine the work function of evaporated amorphous silicon (a-Si). The work function of unhydrogenated a-Si is found to be  $(4.66 \pm 0.02)$  eV. It is increased by 0.1 eV in hydrogenated amorphous silicon (a-Si:H). The work function is insensitive to variations in substrate temperature between 60 and 250+20 °C. The results are correlated with optical absorption and conductivity data. Limitations of the contact potential difference methods of monitoring changes in the bulk Fermi level are discussed. (Author abstract) 16 refs.

**095136 TRAP-AUGER EFFECT IN RELATIVELY PURE SILICON.** By interpreting published lifetime curves for relatively pure silicon it is shown that the trap-Auger effect can be significant. It is estimated to be  $10^{-24}$  cm<sup>6</sup> s<sup>-1</sup>. At low carrier densities one would not expect the Auger effect to be important. The band-band effect goes at the rate of  $(B_1 + B_2)pnp$  (cm<sup>-3</sup> s<sup>-1</sup>) and this is small if n and p are small. A standard value of  $B_1 + B_2$  is  $3.9 \times 10^{-31}$  cm<sup>6</sup> s<sup>-1</sup>. On the whole, however, the numerical estimates and the fit are very satisfactory, showing that the trap-Auger effect, i.e. the term  $\beta n$ , is important even though the defect density is so small. 3 refs.

## Encapsulation

**095137 EFFECT OF Si<sub>3</sub>N<sub>4</sub> ENCAPSULATION ON THE THERMAL PROCESSING OF HYDROGENATED AMORPHOUS SILICON.** The properties of annealed hydrogenated amorphous silicon (a-Si:H) with and without Si<sub>3</sub>N<sub>4</sub> encapsulation have been studied using Rutherford backscattering spectrometry, forward recoil analysis and scanning electron microscopy. Thermal processing of a-Si:H results in loss of hydrogen at temperatures above 375°C with or without Si<sub>3</sub>N<sub>4</sub> thin film encapsulation. With no encapsulation, the loss of hydrogen is preceded by the formation of bubbles which eventually break to form pinholes on the substrate. However, with Si<sub>3</sub>N<sub>4</sub> encapsulation in the structure Si<sub>3</sub>N<sub>4</sub>/a-Si:H/Si no pinhole formation is observed. (Author abstract) 12 refs.

**095140 APPLICATION OF PHOTO-ASSISTED ETCHING TECHNOLOGY TO PREFERENTIAL ETCHING OF Si FOR DIELECTRICALLY ISOLATED STRUCTURE.** A fabrication sequence of a dielectrically isolated structure by field-assisted bonding of oxidized wafer pairs and preferential etch-back process utilizing a photo-assisted etching technology is presented. The etching technique utilizes the high etch selectivity between an epitaxially grown moderate resistivity layer and a low resistivity n-type substrate. The photochemically etched surface is specular and the thickness variations of the epitaxial layer can be controlled to less than  $\pm 20$  nm across a 3-inch diameter wafer. The process controllability is superior to conventional methods because of the simple etch mechanism. The technique has shown considerable promise for the fabrication of a practical SOI substrate. (Author abstract) 16 refs.

**095141 ETCHED SHAPE CONTROL OF SINGLE-CRYSTAL SILICON IN REACTIVE ION ETCHING USING CHLORINE.** The trench shape formation mechanism is examined during reactive ion etching (RIE) of single-crystal silicon using chlorine for the etching gas, and shape control is achieved through the mixing of the depositing gas. One problem with RIE is undercutting of the sidewall due to divergent ions from ion-molecule collisions. Furthermore, sharp crevices are formed at the trench bottom edges because of the increase in radical concentration at these edges. From the experiment using chlorine, it is found that these problems are suppressed by a simultaneous deposition. Experimentation also showed that the etched depth is independent of the trench width for trenches wider than 0.7 μm, although the sidewall slope only slightly decreased with increasing trench width. (Edited author abstract) 19 refs.

**095143 LIMITATIONS OF ORIENTATION DEPENDENT MICROSTRUCTURE ETCHING IN SILICON.** In this note, we report on an attempt to employ the ODE technique for batch fabrication of cavities suitable for vertically coupling optical fibers to silicon circuitry. The authors' results indicate that it is impossible to select such a limited subset of these planes (e.g., by masking their traces) and neglect the effect of the others. This approach succeeds in one-dimensional trench etching applications because the effect of the oblique {111} planes is seen only at the ends of the long trenches, which may be removed by cleaving. However, the two-dimensional shape of a small mask opening cannot be projected vertically into (110) Si, because of the interference of the non-vertical {111} planes. 9 refs.

**095144 MASK DEPENDENT ETCH RATES III: THE EFFECT OF A SILVER ETCH MASK ON THE PLASMA ETCH RATE OF SILICON.** The authors report their findings using Ag as an etch mask in RIE etching of Si. Silver also enhances the etch rate of Si, and this enhancement is even more dramatic than that observed with Al. It is shown that the mask dependence of plasma etch rates is not limited to Al masks but is also observed with Ag masks. The enhancement of the etch rate with Ag is dramatic, with etch rates many times that of resist. That fact that two different metal masks give different enhancements of the Si etch rate show that the metal mask is responsible for the different rates. The larger enhancement with Ag masks can be partially explained by increased Ag surface area. 2 refs.

**095145 REACTIVE AND CHEMICALLY ASSISTED ION BEAM ETCHING OF SI AND SiO<sub>2</sub>.** Results are presented for the etching of thermal SiO<sub>2</sub> and single crystal Si by two ion beam sources of widely different characteristics, viz., a cold cathode saddle field source and a heated filament source. Reactive ion beam etching in SF<sub>6</sub> is described for both sources and chemically assisted ion beam etching (using a specially constructed inlet system) in SF<sub>6</sub>/Ar<sup>+</sup> using the heated filament source. Etching rates of Si in the latter mode are dependent on reactive gas partial pressure. Reactive and chemically assisted ion beam etching work in CF<sub>4</sub> using the heated filament source is reported. Changes in etch selectivity between Si and SiO<sub>2</sub> are observed. (Author abstract) 50 refs.

**095146 EINFLUSS DER FREQUENZ EINER CF<sub>4</sub>-GLIMMENTLADUNG AUF DAS PLASMA-ÄTZEN VON SILICIUM.** [Effect of Frequency on Plasma Etching of Silicon in a CF<sub>4</sub> Glow Discharge]. In plasma etching of Si, an increase of the excitation frequency of a CF<sub>4</sub> discharge in the region of 10 to 1000 kHz results in a decrease in the Si etching rate. Evaluations of the motion of ions in the space discharge layer of the Si substrate and the discharge voltage, which changes in the course of frequency variation lead, in the discussion of the etching rate progress, to the conclusion that the etching process takes place with the support of ions and the ion energy, is of decisive importance for the etching effect. (Translated author abstract) In German. 13 refs.

Hille, Norbert; Poll, Hans-Ulrich. *Wiss Z Tech Univ Karl Marx Stadt* v 29 n 4 1987 p 540-545.

**095147 EXPERIMENTAL STUDIES ON THE POLISHING MECHANISM OF HP-NONBAKED SiO<sub>2</sub> POLISHING AGENT FOR SILICON WAFERS (PART II).** A rapid removal of the fragments of the oxidic films is a key point to both polishing rate and the polished surface quality. Thus authors further investigated the reductions with use in  $\zeta$ -potential HP colloidal particles

and the surface tension of the polishing agent respectively. Several experiments show that the particles and the solution both exhibit a large capacity to adsorb the fragments, same as the ability toward some metal impurities. To sum up, the authors believe that the polishing mechanism of the HP polishing agent is the comprehensive actions of chemical action, mechanical action, complexing action, adsorption and rinsing, which is most suitable for offering high-quality polished silicon wafers for LSI and VLSI. (Edited author abstract) In Chinese. 11 refs.

**095149 ETCHING OF Si THROUGH SiO<sub>2</sub> IN CF<sub>4</sub>/N<sub>2</sub>O PLASMA.** The etching behavior of CF<sub>4</sub>/N<sub>2</sub>O on silicon and its compounds has been investigated over a wide range of plasma conditions. A peculiar 'tunnel effect' was discovered during this study. That is, when using a mixture of CF<sub>4</sub> and N<sub>2</sub>O operated under high pressure and power conditions, one can etch deeply into silicon through a silicon dioxide layer, resulting in patterned tunnels in the underlying silicon substrate. In contrast, no such effect was observed in a CF<sub>4</sub>/O<sub>2</sub> or a CF<sub>4</sub>/(N<sub>2</sub>+O<sub>2</sub>) plasma under otherwise identical etching conditions. A model for the observations will be discussed. (Author abstract) 8 refs.

Wang, X.W. (Yale Univ, New Haven, Ct, USA); Liu, M.D.; Ma, T.P.; Barker, R.C. *J Electrochem Soc* v 135 n 2 Feb 1988 p 442-445.

**095150 MICROWAVE MULTIPOLAR PLASMA FOR ETCHING AND DEPOSITION.** Microwave Multipolar Plasmas (MMP) are plasmas which are confined by multipolar magnetic fields and excited by 2.45 GHz microwaves. Two main features distinguish MMPs from conventional plasmas: the decoupling of plasma excitation from plasma-surface interactions and the absence of self-bias, allowing independent control of substrate bias and ion impact energy. Microwave excitation is applied in three ways: localized (i.e., conventional) electron cyclotron resonance (ECR), surface wave, and distributed ECR (DECR). All three methods have been used to investigate silicon etching by fluorine, but only DECR seems technologically promising. Silicon homoepitaxy has been done on 100 mm wafers at temperatures down to 400°C in silane MMPs excited by DECR. (Author abstract) 27 refs.

Burke, Rudolf R. (CNRS, Meylan, Fr); Pomot, Claude. *Solid State Technol* v 31 n 2 Feb 1988 p 67-71.

**095151 EXCIMER-LASER ETCHING ON SILICON.** Studies have been made of poly- and single-crystal Si etching induced by excimer-laser irradiation of the silicon surfaces in halogenated gases. Etching was investigated for different conduction types, impurity concentrations and crystallographic planes. The n<sup>+</sup>-type Si is etched spontaneously by Cl<sup>-</sup> as a result of the availability of conduction electrons. Easy F<sup>-</sup> ion penetration into Si causes spontaneous etching in both types. Anisotropic etching for n<sup>+</sup> poly-Si is investigated because of its importance to microfabrication technology. Pattern transfer etching for n<sup>+</sup> poly-Si has been realized using reflective optics. The problems involved in obtaining finer resolution etching are discussed. (Edited author abstract) 26 refs.

Horiike, Y. (Toshiba Research & Development Cent, Kawasaki, Jpn); Hayasaka, N.; Sekine, M.; Arikado, T.; Nakase, M.; Okano, H. *Appl Phys A* v A44 n 4 Dec 1987 p 313-322.

**095152 SINGLE SILICON ETCHING PROFILE SIMULATION.** Single Si etching profiles by Cl<sub>2</sub> and a mixture of Cl<sub>2</sub> and CHF<sub>3</sub> are discussed in terms of experimentation and simulation. A microprobe Auger analysis of a trench side wall has proven that the bombardment of obliquely impinging ions to a side wall leads to both concave and tailed features. In the case of a mixture of Cl<sub>2</sub> and CHF<sub>3</sub> protects the side wall from species impinging from an inclined direction. Furthermore, the difference in the polymer sputtering rate, resulting from subsequently impinging ions between the tailed part and the flat bottom regions improves the tailed part of the rectangular bottom. A profile simulation supports the idea that obliquely impinging species, polymer deposition and sputtering of a polymer are important factors in determining the single Si etching profile. (Author abstract) 8 refs.

**095153 STUDY OF REACTIVE ION ETCHING OF SI AND SiO<sub>2</sub> FOR CF<sub>x</sub>Cl<sub>4-x</sub> GASES.** A parametric study of the etching of Si and SiO<sub>2</sub> by reactive ion etching (RIE) was carried out to gain a better understanding of the etching mechanisms. The Si etch rate uniformity across the wafer as a function of the temperature of the wafer and the Si load, the optical emission as a function of the temperature of the load, the etch rate of SiO<sub>2</sub> as a function of the sheath voltage, and the mass spectra for each of the FCs were measured. (Edited author abstract)

Fortuno, Guadalupe (IBM, Hopewell Junction, NY, USA). *Plasma Chem Plasma Process* v 8 n 1 Mar 1988 p 19-34.

**095154 RECOVERY OF SI SURFACES SUBJECTED TO REACTIVE ION ETCHING USING RAPID THERMAL ANNEALING.** In a recent report, we demonstrated that rapid thermal annealing (RTA) can be successfully used to recover the surface properties of silicon exposed to reactive ion etching (RIE) in a case where there was no substantial residue (non-silicon) layer produced by the RIE. The RIE process, for which RTA was successful, was CCl<sub>4</sub> blanket etching of bare Si wafers. In that report we suggested that RTA could be successfully employed for the recovery of Si surfaces exposed to other RIE processes, if residue layers were removed prior to rapid thermal annealing. In this study we substantiate that assertion for the case of silicon exposed to CClF<sub>3</sub>/H<sub>2</sub> RIE. It is pointed out that the complete evolution of Au/Si contact (1 mm, 1000 Angstrom thick Au dots) electrical behavior for three various processing steps is presented. Shown are the I-V data for a dot to a control surface (curve a), a dot to an RIE-exposed surface (curve b), a dot to an RTA/O<sub>2</sub> ashed/RIE-exposed surface, and a dot to an HF etched/RTA/O<sub>2</sub> ashed/RIE-exposed surface. 7 refs.

**095156 CHEMICAL ETCHING OF SILICON BY CO<sub>2</sub>-LASER-INDUCED DISSOCIATION OF NF<sub>3</sub>.** The pulsed infrared laser dissociation of NF<sub>3</sub> is reported for the first time, and is used to investigate silicon etching. The role played by collision-enhanced multiple-photon absorption and dissociation is considered, with data on the nonlinear decrease of the absorption cross-section with increasing pulse energy and increasing pressure presented. Using an experimental arrangement in which the laser beam is focussed parallel to the surface, the dissociation process induces spontaneous etching of silicon. Etching was monitored by use of a quartz-crystal microbalance upon which a thin film of amorphous silicon was deposited. For a surface with no previous exposure to the photolysis products, dissociation causes the formation of a surface layer prior to the onset of etching. X-ray photoelectron spectroscopy demonstrates this to be a fluorosilyl layer possessing a significant concentration of SiF<sub>3</sub> and SiF<sub>4</sub>. In contrast, a surface already thickly fluorinated does not form a thicker layer once laser pulsing commences again. In this case, etching starts immediately with the first pulse. The etch yield dependencies on several parameters were obtained using silicon samples possessing a thick fluorosilyl surface layer. Attempts at etching SiO<sub>2</sub> under identical conditions were unsuccessful. (Edited author abstract) 42 refs.

**095157 Nb REDEPOSITION ON SI DURING PLASMA ETCHING OF Nb/SiO<sub>2</sub>/SI LAYERS INVESTIGATED BY RBS.** The redeposition of electrode material (Ni, Cr, Al) and material of a Nb layer on silicon surface during plasma etching of Nb, SiO<sub>2</sub> and Si by a CF<sub>4</sub> plasma has been investigated by Rutherford Back Scattering spectrometry. It is shown that a steady state (NbF<sub>x</sub>)<sub>gas</sub> ↔ (Nb)<sub>ads</sub> + xF exists, what causes a Nb contamination of etched Si surfaces. Obviously this steady state concentration (Nb)<sub>ads</sub> is influenced by additional redeposition of non-etchable electrode material as Ni, Cr and Al. (Author abstract) 6 refs.

**095158 ETCH RATE DISTRIBUTION OVER SILICON WAFERS IN EPW SOLUTIONS.** Anisotropic etching of silicon wafers in ethylenediamine-pyrocatechol-water (EPW) solutions was carried out to reveal the distribution of etch rates over the wafer. The etch depth, i.e., the etch rate on the wafers, was found to vary within a few percent about the average value, and the standard deviation depended on the etch conditions such as temperature and flow patterns in the solution. The distribution was shown as a map and statistically analyzed. The major factor affecting the distribution was found to be the mass transfer in the solution via flow patterns in the solution. (Author abstract). 7 refs.

**095159 TRENCH ETCHES IN SILICON WITH CONTROLLABLE SIDEWALL ANGLES.** This paper describes the role of the temperature of the silicon wafer in controlling a deep trench etch sidewall angle and also the etch rate. In addition, it discusses the role of pressure in controlling etch rate and selectivity. This work was performed in a Tegal 1500 Test Bench. The temperature of the wafer could be held fixed as a function of time at any temperature between 20° and 200°C. Our chemistry is chloroform, CHCl<sub>3</sub> with O<sub>2</sub> and N<sub>2</sub> as additives. We have

found that the sidewall angle of the trench (the angle that the sidewall makes with a normal to the wafer surface) could be varied continuously from about 32° at 40°C to 7° at 190°C. The sidewalls are typically planar and relatively smooth. The bottom of the etch becomes increasingly planar as sidewall angle decreases. (Edited author abstract). 10 refs.

**095160 ELECTRON CYCLOTRON RESONANCE MICROWAVE-PLASMA ETCHING.** Electron cyclotron resonance microwave-plasma etching of Si and SiO<sub>2</sub> using a (CF<sub>4</sub> + O<sub>2</sub>) gas mixture is investigated in a magnetically confined plasma. High etch rates have been obtained at 0.8 Torr pressure, where the etching mechanism may be due primarily to neutral active species (1 Torr = 133 Pa). The high etch rate can be explained by a high dissociation efficiency of the ECR microwave plasma, and the directionality by carbon deposits associated with it. The magnetic confinement is likely to play a role similar to that of ion and electron screening. (Author abstract) 8 refs.

**095161 RIE ETCHING OF DEEP TRENCHES IN Si USING CBrF<sub>3</sub> AND SF<sub>6</sub> PLASMA.** A two step RIE etch process offers the capability to form deep trenches with ideal profiles in bulk silicon. The first step in CBrF<sub>3</sub> transfers the pattern of the structured tri-level system into the silicon. Because the sidewalls are not smooth and the corners at the bottom of the 4 to 6 µm deep trenches are relatively sharp, a further short etch step in SF<sub>6</sub> was introduced. The RIE with CBrF<sub>3</sub> results in an anisotropic etch of Si compared to SF<sub>6</sub> which leads due to the isotropic etch behavior to smooth and slightly tapered sidewalls and to a rounded bottom. (Author abstract) 8 refs.

**095163 ANISOTROPIC ETCHING OF SILICON IN HYDRAZINE.** This paper contains a detailed discussion of the practical issues related to the anisotropic etching of single crystal silicon using a 50-50 hydrazine-water solution. Characteristics of the etchant, etching reactor design, etch procedures, safety precautions, etch rate data for typical samples and appropriate etch-masks are among the topics discussed. The etching process is carried out in an atmospheric reflux reactor, continuously purged with nitrogen. The etch rate of (100) silicon at 115°C in this hydrazine solution is nearly 3 µm/min, which is much higher than that of ethylenediamine-pyrocatechol-water (EDP) solutions. Silicon dioxide, silicon nitride and most metallic thin films, except aluminium, can be used to mask the etching process. The etch rate is reduced significantly in highly-boron-doped silicon; a boron concentration of  $1.5 \times 10^{20} \text{ cm}^{-3}$  practically stops the etch. The use of the hydrazine

solution for micromachining thin silicon diaphragms, cantilevers and fibers is demonstrated. (Author abstract) 68 refs.

## Fracture

**095164 DYNAMICS OF DISLOCATION GENERATION AT CRACK TIPS AND THE DUCTILE-BRITTLE TRANSITION.** During the last few years there has been interest in the phenomena which control whether crystalline solids containing cracks deform in a brittle or ductile manner. One of the main conclusions is that the role of dislocations generated from external sources, as compared with that of dislocations nucleated at and emitted from the crack tip, in controlling T<sub>c</sub> is not understood. The purpose of the present paper is to report on some recent experiments on Si and theoretical computations which address this and other problems covering the ductile-brittle transition of intrinsically brittle materials. Fracture experiments were carried out using 4-point bend tests on rectangular bars of float zone Si. 15 refs.

**095165 INFLUENCE OF PRECIPITATED OXYGEN ON THE BRITTLE-DUCTILE TRANSITION OF SILICON.** The degree of brittleness of silicon during cutting depends on oxygen content and previous heat treatment. The authors report on the ductile-brittle transition of three grades of Si in various stages of oxide precipitation but at one particular crack opening rate ( $\dot{\delta} = 50 \text{ µm/min}$ ). They analyzed the ductilization process by scanning electron microscopy. 8 refs.

**095166 FRACTURE OF SILICON WAFERS.** This paper examines the fracture strength of a wide range of silicon material both as-grown and after processing. The wafers tested were from crystals grown by float-zone and Czochralski techniques and the effects of oxidation, ion-implantation and annealing in various environments have been studied. The technique used to measure the fracture stress involved simply supporting the wafer on an aluminum ring concentric to the load axis. The load was gradually increased until the wafer fractured. In the first part of the study, the role of the surface on the fracture behavior has been investigated in detail. Results can be analyzed in terms of surface controlled defects under conditions where surface defects are dominant and bulk controlled defects where these defects are dominant. **095170 SILICON MOLECULAR BEAM EPITAXY ON GaP AND GaAs.** Thin silicon films have been epitaxially grown on GaP and GaAs by molecular beam epitaxy (MBE). Films and interfaces have been investigated by surface analysis and transmission electron microscopy. Both the surface and the bulk of the films are contaminated by atoms from the substrate; this is attributed mainly to surface diffusion and exchange between Si and Ga atoms. On GaP, films thinner than 75 nm are subject to tensile stress because of the lattice mismatch (0.36%), without the appearance of crystal imperfections. Thicker films contain dislocation and stacking faults, related to strain-induced atomic rearrangements. The critical thickness for dislocation formation is significantly larger than is predicted from elasticity theory. On GaAs, the lattice mismatch of 4% gives a greater reduction in crystal quality. (Author abstract) 27 refs.

**095171 GaAs ON Si TECHNOLOGY.** High quality GaAs layers were grown on Si(100) wafers by the heat treatment of the substrates at high temperatures and a subsequent two-step growth sequence at low temperature and then at the conventional growth temperature. The grown layers showed a high quality, single domain structure, a mirror-like surface, high electron mobility, fairly high photoluminescence intensity and low etch pit density. A small offset angle from (100) was necessary to grow a single domain GaAs layer. (Author abstract) 36 refs.

**095172 INVESTIGATION OF VARIOUS SUBSTRATE DOPANTS AND EPITAXIAL GROWTH TECHNIQUES FOR PRODUCING SHARP TRANSITION EPITAXIAL WAFERS.** Arsenic, antimony, phosphorus, boron, and gallium doped silicon substrates were used for the fabrication of n/n+ or p/p+ epitaxial wafers to study autodoping effects in a horizontal induction heated atmospheric pressure epitaxial reactor. Using the 'high-low' technique which uses a high temperature prebake (without HCl etching) followed by a relatively

low temperature and slow growth rate deposition, sharp n/n+ transition on arsenic material was achieved. This method appears to produce an epitaxial layer of more uniform resistivity out to the beginning of the transition region for all of the n-type substrates used. Results show that when the epitaxy employs the high-low technique at a temperature of 1050°C, heavily doped arsenic substrates offer unique transition and defect density advantages over either antimony or phosphorus material. (Edited author abstract) 11 refs.

**095173 SELECTIVE DOPED POLYSILICON GROWTH: EFFECT OF CARBON ON THE SELECTIVE DOPED SILICON FILM GROWTH.** We previously discussed selective polysilicon growth technology based on selective epitaxial growth technology. In this paper, we report the influence of CH<sub>4</sub>-introduction on the crystallinity of silicon, the doping control with PH<sub>3</sub>, and the selective growth of silicon. It has become possible to control the transition from epitaxial silicon to polysilicon and  $\beta$ -SiC. By achieving a definite doping control, the resistivity can be lowered to  $1 \times 10^{-3} \Omega \cdot \text{cm}$ . A combination of these technologies made it possible to grow selectively doped polysilicon with a flat surface. (Edited author abstract) 8 refs.

**095175 PROPERTIES OF SILICON CRYSTALS GROWN UNDER THE ACTION OF A VERTICAL MAGNETIC FIELD.** The possibility of obtaining 100-mm-diam silicon single crystals with a low oxygen content (up to  $2 \cdot 10^{17} \text{ cm}^{-3}$ ) at relatively low magnetic field strengths is shown. In crystals grown under magnetohydrodynamic action, a more ordered distribution of microdefects is formed, which is attributed to the nature of the temperature fluctuations in the melt. The electrical and structural parameters of these crystals are thermally stable. (Translated author abstract) In Russian. 10 refs.

**095176 MELT MOTION IN A CZOCHRALSKI CRYSTAL PULLER WITH AN AXIAL MAGNETIC FIELD: UNCERTAINTY IN THE THERMAL CONSTANTS.** For a Czochralski silicon puller with a uniform axial magnetic field of at least 0.2 T (2000 G), the melt velocities are so small that the inertial effects can be neglected and viscous effects are confined to thin layers. Analytical solutions of the momentum equation are possible and provide physical insights into the melt motions. The asymptotic analysis for strong magnetic fields is used to treat the effects of changing the values of the thermal conductivity, coefficient of volumetric expansion and thermal gradient of surface tension. With a particular choice for the characteristic velocity, the dimensionless stream functions for the melt motions are relatively independent of the thermal conductivity and depend

on the thermal expansion coefficient and surface tension gradient only through a single parameter reflecting the ratio of these two thermal constants. Variations with magnetic field strengths from 0.2 to 1.7 T are discussed as well. (Author abstract) 14 refs.

**095180 FORMATION OF NUCLEI OF OXYGEN PRECIPITATES IN CZ SILICON CRYSTALS DURING CRYSTAL GROWTH PROCESS.** The effects of the thermal history during CZ process conformation of the nuclei of the oxygen precipitates are investigated by the annealing experiments on as-grown crystals and a special crystal growth experiment. In the annealing experiments, the thermal histories similar to those during crystal growth are given to the specimens and their effects on oxygen precipitation are examined. In the growth experiment, the crystal is subjected to the duplicated in situ annealing in the crystal puller and the effect of the thermal history, particularly that in the intermediate temperature range, is examined. On the basis of the present results, the formation process of the nuclei during crystal growth is summarized. (Edited author abstract) 13 refs.

**095181 PREGROWTH AMBIENT GAS ANALYSIS OF CZOCHRALSKI Si CRYSTAL PULLER.** The nature of the ambient gas during vacuum bakeout of a Czochralski silicon crystal puller was investigated by

using a commercially available residual gas analyzer. The ambient pressure changes observed during bakeouts were correlated with the relevant gas profiles generated from the residual gas analyzer. The partial pressures and the percent compositions of the ambient gas species were then calculated. Among the major species found during vacuum bakeouts were CO, CH<sub>4</sub>, H<sub>2</sub>O, and Ar. CH<sub>4</sub> and H<sub>2</sub>O completely vanished within 2-4h into the bakeout, and the steady-state ambience was composed mostly of CO gas. The prime source of CO was apparently the reduction of the fused quartz crucible by its graphite holder. (Edited author abstract) 15 refs.

**095183 EDDY CURRENT MONITORING SYSTEM AND DATA REDUCTION PROTOCOL FOR CZOCHRALSKI SILICON CRYSTAL GROWTH.** A computer controlled eddy current system for the in situ monitoring of Czochralski silicon crystal growth is introduced. A scheme to reduce eddy current sensor data to temperature values and thermal profiles in the growing crystal is presented. The principle of eddy current testing involves the behavior of electromagnetic radiation penetrating the silicon crystal and its subsequent reflection. This behavior is outlined by Maxwell's equations, and it is the solution of the electromagnetic field boundary-value problem that relates voltage measurements from the eddy current probe to the changing electrical conductivity of the crystal. Due to a strong temperature dependence of the electrical conductivity in solid silicon, it is then possible to determine thermal profiles within the growing crystal. (Author abstract) 27 refs.

Stefani, J.A. (Columbia Univ, New York, NY, USA); Tien, J.K.; Choe, K.S.; Wallace, J.P. *J Cryst Growth* v 88 n 1 Apr 1988 p 30-38.

**095184 EDDY CURRENT MEASUREMENT OF CRYSTAL AXIAL THERMAL PROFILES DURING CZOCHRALSKI SILICON CRYSTAL GROWTH.** The axial thermal profiles of silicon crystals during the Czochralski crystal growth process were measured experimentally by using an eddy current technology. The intrinsic conductivity changes in the crystal resulting from cooling were measured in terms of the eddy current amplitude and phase responses, and the axial thermal profiles of the growing crystal were subsequently derived from the results. The experimental results indicate that the axial thermal profile in the region is nearly linear and quite transient during the initial phase of body growth. As the crystal gets longer, the increasing heat loss by radiation from the crystal surface causes the overall profile to shift downward. When the crystal reaches 200-250 mm in length, a steady state condition is achieved, and the overall axial thermal profile stays nearly invariant for the remainder of the growth. The steady state axial thermal gradient in the region is estimated to be about 4-6°C/mm. (Edited author abstract) 25 refs.

**095189 EPITAXIAL GROWTH OF CrSi AND CrSi<sub>2</sub> ON Si(111).** The possibility of epitaxial growth of chromium silicides upon thermal processing of thin Cr deposits ( $\leq 30$  monolayers (ML)) on Si(111) is demonstrated using low energy electron diffraction (LEED) and angle resolved X-ray (XPS) and ultra-violet (UPS) photoemission. For coverages  $\theta \geq 4$  ML epitaxial CrSi with a lattice misfit of  $\approx 1.6\%$  can be grown upon annealing at 350°C. Thermal treatment at 450°C for  $\theta \geq 6$  ML results in epitaxial CrSi<sub>2</sub> formation with two kinds of domains rotated by 30° with respect to each other around the surface normal. LEED intensities indicate essentially equal formation probabilities for both orientations despite the large difference in lattice misfit of  $\approx 0.1$  and  $\approx 3.8\%$ , respectively. (Author abstract) 6 refs.

**095191 GROWING SILICON SINGLE CRYSTALS BY THE METHOD OF VERTICAL DIRECTED CRYSTALLIZATION IN GRAPHITE CRUCIBLES.** The advantages of the method of vertical direct crystallization (VDC) over the widely used Czochralski method is the low cost of the crystals, high productivity, and simplicity in control of the process, as well as the possibility of obtaining ingots of any cross section. In our study we show that it is possible to grow single crystals of silicon by the VDC method in inexpensive crucibles made from modified graphite. A thermal assembly has been developed that contains a heater, a crucible, and heat insulation. The crucible is installed within the heater on a graphite rod. To control the structure of the crystal being grown it is necessary to act on the shape of the crystallization front (CF). This is done most simply by varying the relationship of the heat fluxes from center and from the periphery of the bottom of the crucible. In the thermal assembly developed the CF shape was regulated by varying the thermal resistance of the rod.

**095192 DIRECT OBSERVATION BY X-RAY RADIOGRAPHY OF CONVECTION OF MOLTEN SILICON IN THE CZOCHRALSKI GROWTH METHOD.** Convection of molten silicon during Czochralski single crystal growth was directly observed using X-ray radiography. The melt flow pattern was monitored using a tracer method. The tracer, whose density and wettability were adjusted to that of the molten silicon, was developed. The observed convection of the molten silicon in the crucible was not only steady but also transient, and not axisymmetric but asymmetric. This asymmetry is attributed to the asymmetric temperature distribution within the crucible. The flow velocity of the molten silicon in the 75 mm diameter crucible was 10 to 20 mm/s. (Author abstract) 16 refs.

**095193 ELECTRICAL SIZE EFFECTS OF THIN C54-TiSi<sub>2</sub> FILMS GROWN ON SILICON SUBSTRATES.** The temperature dependences of the Hall constant  $R_H$  and resistivity at various thicknesses for C54-TiSi<sub>2</sub> films grown on (111) and (100) silicon substrates were measured. The resistivity increases as temperature increases with a character incongruent with the Bloch-Grüneisen equation as followed by normal metals. The magnitude of  $R_H$  has a flat appearance at high temperatures (for  $T > 400$  K), and increases as the temperature decreases and reaches a maximum value near 360 K, and then decreases to reverse the sign at low temperatures. The thinner the film thickness, the higher the temperature for sign reversal. The experimental data can be satisfactorily explained by the classical size effect and two-band model. (Author abstract) 14 refs.

**095195 SCIENCE AND ENGINEERING OF LARGE-DIAMETER CZOCHRALSKI SILICON CRYSTAL GROWTH.** Silicon is the major semiconductor material used in solid state electronics. To keep pace with the growth in integrated circuit size and complexity, silicon has to be prepared in single crystal form with continued increases in size and improvements in perfection. Modern integrated circuits called VLSI (for Very Large Scale Integration) and future circuits called ULSI (for Ultra Large Scale Integration) depend upon the availability of highly perfect single crystals which are prepared almost exclusively from silicon pulled from the melt by the Czochralski (CZ) technique. In this review the major advances in the understanding and engineering of this technology are discussed for crystals of 100 mm in diameter and approximately 20 kg in mass. 50 refs.

**095196 INFLUENCE OF DIFFERENT DEPOSITION PARAMETERS ON THE PROPERTIES OF HYDROGENATED AMORPHOUS SILICON FILMS PREPARED BY MAGNETRON SPUTTERING.** Hydrogenated amorphous silicon films have been reactively sputtered with different flow rates of hydrogen in an Ar-H<sub>2</sub> gas mixture. The films have been characterized with respect to optoelectronic and structural properties. The susceptibility to light-induced changes has been studied. The effects of variation of the rf power density and the total pressure on the film properties have also been examined. Each of the deposition parameters has been found to exercise considerable control on the film characteristics. Parametric optimization has yielded encouraging results in terms of film quality. **095197 CORRELATIONS BETWEEN THERMAL DONOR FORMATION, ROD-LIKE DEFECT FORMATION, AND OXYGEN REDUCTION DURING LOW-TEMPERATURE ANNEALING OF CZ-GROWN SILICON.** Complex investigations of the oxygen reduction, TD and RLD formation are described for annealing at temperatures from 440 up to 500°C for 200 to 1500 h. The measurements of the TD activity refer to different species which only partially correspond to the double donors. The oxygen reduction as well as the TD activity point to the existence of silicon self-interstitials. The strong influence of self-interstitials is also derived from the defect formation during annealing at these temperatures. It is found that besides RLD's also isolated defects parallel to {111} habit planes exist showing contrasts which indicate an analogous crystalline structure as previously described for RLD's. Supposing that self-interstitials are the dominant point defect type for the TD and RLD formation, a model of precipitation processes in the low-temperature region is discussed. (Edited author abstract). 29 Refs.

**095198 MASS TRANSPORT IN A CZOCHRALSKI PULLER WITH A STRONG MAGNETIC FIELD.** This paper treats the mass transport of oxygen in a Czochralski silicon crystal puller with an extremely strong, uniform, axial magnetic field. The problem is intrinsically unsteady and the oxygen concentration of a crystallizing particle depends on its trajectory since the beginning of crystal growth. The results provide the base solution for the mass transport problem with much weaker magnetic fields. (Author abstract) 5 refs.

**095200 EFFECTS OF BORON CONCENTRATION UPON OXYGEN PRECIPITATION IN CZ SILICON.** Effects of boron concentration upon oxygen precipitation were studied in Czochralski (CZ) silicon annealed from 2 to 128 h between 450 and 1050°C. In this investigation Bragg line profile (BLP), high resolution diffuse X-ray scattering (DXS) and transmission electron microscopy (TEM) were employed. The BLP and DXS data have shown that the nature of the predominant defects depend upon annealing time and temperature, as well as, on dopant concentration. The long range displacement field of these defects, however, does not seem to be affected by these parameters. The TEM results have shown a dependence of precipitate growth kinetics, as well as, structure upon dopant concentration, and annealing temperature and time. Differences in oxide precipitate growth kinetics between lightly and heavily doped materials and a correlation between DXS parameters and TEM images are discussed. (Author abstract) 16 refs.

## Heat Treatment

**095202 EFFECT OF HEAT TREATMENT ON THE STATE OF THE IMPURITIES IN SINGLE-CRYSTAL SILICON.** The changes occurring in a silicon solid solution under the action of heat treatment in the 300-1300°C temperature range were studied by the IR

absorption method. It was found that in the temperature range in which changes in the structural and electrical parameters occurred. There was a simultaneous decrease in the oxygen, carbon, boron and phosphorus concentrations in the silicon solid solution. (Translated author abstract) In Russian. 9 refs.

Guskina, L.G.; Fal'Kevich, E.S. *Tsvet Met* n 9 Sep 1987 p 58-59.

**095203 HIGH-TEMPERATURE TREATMENT OF HEM POLY-SI.** Polycrystalline silicon (poly-Si) is one of the prospective materials for solar energy conversion. The author studied the high-temperature effects on HEM-type poly-Si. Thermal treatment was carried out in a nitrogen atmosphere so that nitrogen caused dislocation locking close to the surfaces and prevented out-diffusion of oxygen and carbon. Therefore, out-diffusing impurities were precipitated close to the surface forming [C, O] complexes and amorphous SiO<sub>2</sub> phase and giving rise to the observed infrared spectra. 6 refs.

**095204 NUCLEATION KINETICS OF PLATE-LIKE OXIDE PRECIPITATES IN Cz-SILICON.** A quantitative model of nucleation kinetics of platelike oxide precipitates in Czochralski-grown silicon is presented. Some features of the precipitate formation neglected in previous models are taken into consideration, i.e., the shape of precipitates, large volume misfit of Si matrix and oxide precipitates as well as partial relaxation of resulting strain energy by the emission of self-interstitials. The results are in good agreement with experimental findings such as 1) the dependence of the oxide precipitate nucleation rate on the interstitial oxygen content in silicon and 2) the shape of precipitates and the rate of self-interstitial emission determined by HREM and infrared spectroscopic investigations, respectively. (Edited author abstract) 28 refs.

**095205 ONE- AND TWO-DIMENSIONAL NON-LINEAR DOPANT DIFFUSION IN CRYSTALLINE SILICON - SOME ANALYTICAL RESULTS.** The diffusion of dopant in crystalline silicon during heat treatment is dependent on the dopant concentration; in particular it is enhanced at high concentrations. Simple mathematical models of this process result in a nonlinear diffusion equation. This paper considers such a model with an initial 1-D Gaussian implant profile and for a simple 2-D implant near a mask edge. Non-dimensional parameters are identified which represent the amount of enhancement, the depth of the implant and the time of the heat treatment relative to physical parameters in the problem. Analytical expressions are presented for the concentration showing junction depths and local structure for various limiting cases of the parameters. Of particular interest is the case of large enhancement when the results include not only those derived elsewhere for the high concentration region but also the detailed structure of the steep front near the junction. Comparison with numerical results is also included. (Author abstract) 9 refs.

## Hydrogenation

**095206 PHYSICAL PROPERTIES AND MICROSTRUCTURE OF AMORPHOUS HYDROGENATED SILICON FILMS.** The technological parameters largely determine the microstructure and composition of an amorphous hydrogenated silicon film. With an increase in the monosilane concentration in the gas mixture and a constant rate of film deposition there is a decrease in the localized-state density at the Fermi level, in the photoconductivity activation energy, in the hydrogen content, and in the SiH<sub>2</sub>/SiH ratio, which, in turn, leads to a decrease in the size of the microinhomogeneities

in the film. Films with a high SiH<sub>2</sub>/SiH ratio have a columnar microstructure and a developed surface relief. In films with a homogeneous structure the monohydride bond type is dominant. The relative photosensitivity and the band gap in films with a homogeneous structure vary very little during variation of the deposition parameters. 9 refs. In Russian.

## Imaging Techniques

**095207 NEW MECHANISM FOR SUBSURFACE IMAGING IN SILICON.** We report the use of photo-thermal radiometric microscopy to image through silicon wafers. Experimental results are presented which show that the signal obtained decreases as the normal emissivity of the material on the back surface increases. The theory for the emissivity of partially transparent objects has been extended to explain these findings. We conclude that the contrast is due to photon-induced switching of the infra-red transmission coefficient of the silicon. (Author abstract) 6 refs.

**095208 SELECTIVE TRAPPING OF SELF-INTERSTITIALS BY INTERSTITIAL CARBON IMPURITIES IN ELECTRON IRRADIATED SILICON.** Float-zone silicon doped with carbon ( $1.6 \times 10^{17} \text{ cm}^{-3}$ ) has been irradiated with 2 mev electrons below 220 K up to a dose of  $1.9 \times 10^{18} \text{ electrons cm}^{-2}$  leading to a monotonic decrease in the concentration of the substitutional impurity. Interstitial carbon is produced but its concentration saturates and then falls because the defects trap mobile self interstitials. New infrared absorption lines at 966 and  $959 \text{ cm}^{-1}$  (77 K) are ascribed to a C<sub>2</sub>-Si<sub>2</sub> pair defect which also acts as a nucleation site for agglomeration of Si<sub>1</sub> atoms. The latter reactions appear to occur during irradiations at 300 K. (Author abstract) 24 refs.

**095212 INVESTIGATION OF ELECTRONIC STRUCTURES FOR INTERSTITIAL 4D TRANSITION-METAL IMPURITIES IN SILICON.** Electronic structure calculations of interstitial 4d transition-metal impurities in silicon have been performed within the framework of Scattered-Wave X $\alpha$  method. The cluster Si<sub>10</sub>Si<sub>16</sub>, which is centered on the tetrahedral interstitial position, is used to simulate the bulk of silicon, where sixteen Si<sup>+</sup> represent the atoms at the cluster surface. In order to eliminate the dangling bond effects, the Si<sup>+</sup> atom is assumed to be the hydrogen atom with the statistical exchange parameter  $\alpha_{\text{Si}}$ . Placing a neutral 4d impurity atom (Pd, Rh, Ru, Tc or Mo) at the center of the cluster Si<sub>10</sub>Si<sub>16</sub>, the new cluster XS<sub>10</sub>Si<sub>16</sub> (X stands for one of the mentioned impurity atoms) simulating the crystal locally perturbed by interstitial impurity atom is constructed. (Edited author abstract) 19 refs. In Chinese.

**095214 EVALUATION OF INTRINSIC GETTERING OF GOLD BY OXIDE PRECIPITATION IN CZOCHRALSKI SILICON.** Intrinsic gettering of gold in Czochralski single-crystal silicon was evaluated using neutron activation analysis and electron beam microprobe analysis. Silicon wafers were subjected to oxygen denuding and heat-treatment cycles which produced a defect structure, adjacent to a defect-free region, of either oxide particles, oxide particles and stacking faults at mixed ratios, or stacking faults alone. These were produced to evaluate the possibility of gettering of gold from the defect-free region by mechanisms of dislocation-metal interactions, dislocations associated with stacking faults, stacking faults, or interstitial-metal interactions. None of these mechanisms were found to cause gettering. (Edited author abstract) 23 refs.

**095215 NATURE OF NITROGEN-OXYGEN COMPLEXES IN SILICON.** The nature of nitrogen-oxygen complexes acting as shallow donors in silicon was investigated by measuring the optical absorptions due to the electronic transitions associated with donor electrons. The complexes were eliminated by heat treatment at temperatures higher than 1100°C. The generation processes of nitrogen-oxygen complexes of several kinds were traced by means of both isochronal and isothermal annealings. An analysis of the result led to a picture in which the

complexes of the dominant type consist (each) of one oxygen atom and two or three pairs of nitrogen atoms. (Author abstract) 9 refs.

**095216 PARAMAGNETIC RESONANCE OF A Se-AL COMPLEX IN SILICON.** In selenium diffused, aluminium doped silicon a new electron paramagnetic resonance (EPR) spectrum, Si-NL31, was observed as a broad structure superposed on the selenium pair resonance. The EPR spectrum could not be analyzed directly, but an intense <sup>27</sup>Al electron nuclear double resonance (ENDOR) spectrum of trigonal symmetry was found to be related to it. The small hyperfine interaction combined with the large quadrupole effect are evidence for a negatively charged, substitutional Al acceptor, with a donor at the nearest neighbour position. By field scanned ENDOR the EPR spectrum could be analysed. The small anisotropy and shift of the g-value with respect to the free electron value is circumstantial evidence for the presence of a selenium double donor. The nearly vanishing contact density on the <sup>27</sup>Al nucleus is evidence for a doublet ground state, for which the defect axis lies in a nodal plane. This explains why the EPR spectrum shows no resolved <sup>77</sup>Se hyperfine structure. The connection to the infrared complex Si:Se(X<sub>1</sub>), which also has a doublet groundstate, is discussed. (Author abstract) 26 refs.

van Oosten, A.B. (Univ van Amsterdam, Amsterdam, Neth); Ammerlaan, C.A.J. *Solid State Commun* v 65 n 9 Mar 1988 p 1039-1044.

**095217 ELECTRON PARAMAGNETIC RESONANCE OF THE Mn<sub>4</sub><sup>0</sup> CLUSTER IN SILICON.** In high-resistivity p-type and n-type silicon doped with manganese the Mn<sub>4</sub><sup>0</sup> cluster is identified by EPR. The spectrum shows a characteristic hyperfine structure and an angular dependence of fine structure at 20 K. The analysis of the spectrum yield the assumption of the following cluster model: the cluster consists of four Mn<sup>0</sup> atoms on nearest interstitial sites; it has cubic/tetrahedral symmetry; spin multiplets with S=0,1,2,3,4,5, and 6 are produced by dominant exchange coupling where the multiplet with S=6 is the ground state observed by the EPR experiments. The photo-EPR results suggest a donor level (Mn<sub>4</sub>)<sup>0/30</sup> near midgap. (Author abstract) 14 refs.

**095225 LATTICE DISTORTIONS INDUCED BY CARBON IN SILICON.** X-ray double-crystal diffraction has been used to investigate the lattice distortions in silicon crystals containing carbon impurities. Precise lattice-spacing measurements have been carried out with a double-source double-crystal transmission technique. A linear correlation between the absolute value of lattice spacing and the carbon concentration was observed. X-ray double-crystal reflection topography was used to measure residual minute lattice strains also as a function of the carbon atom number density. A similar relationship was found. A comparison of the results of the lattice-spacing measurements and of the topographic investigations indicates that the lattice consists of consecutive layers

which are alternately more and less carbon enriched. The observed lattice deformations arise from the substitutional exchange of silicon and carbon atoms. (Author abstract). 15 Refs.

**095227  $\gamma$ -RAY AND SMALL-ANGLE NEUTRON SCATTERING STUDY OF OXYGEN PRECIPITATION IN SILICON SINGLE CRYSTALS.** Oxygen precipitation in heat-treated Czochralski-grown silicon single crystals has been investigated using  $\gamma$ -ray diffraction combined with small-angle neutron scattering and infrared absorption measurements. Diffuse scattering around the diffraction peaks was observed using  $\gamma$ -rays and this is associated with oxygen precipitation in the silicon lattice. The analysis of the diffuse scattering produces an average precipitate size in agreement with small-angle neutron scattering measurements. (Author abstract). 14 refs.

**095228 HYDROGEN IN Si: DIFFUSION AND SHALLOW IMPURITY DEACTIVATION.** We analyze the total H profiles obtained from secondary ion mass spectrometry data (SIMS) using (a) the model of H diffusion in the presence of strong trapping, which is the most widely accepted today, and (b) a new electric field enhanced diffusion (drift) model which is supported by recent experimental observations and theoretical predictions of a H-donor state in the band gap. The second model gives excellent fits of the SIMS data over the entire explored temperature range and accounts for the observed dependence of the H penetration depth on impurity type. 63 refs.

**095229 OXYGEN DONOR IN SILICON.** The effect of uniaxial stress upon the helium-like infrared absorption spectrum of the oxygen donor in Si has been examined for both the neutral and singly ionized charge states. Contrary to the well-known results for substitutional donors in Si, no splittings of the spectral features were observed for a 001 stress direction. Small splittings were observed for 110 and 111 stress directions that are a characteristic of a C<sub>2v</sub> anisotropy. Our results are consistent with an effective-mass-like ground state wave function that is constructed from the single pair of conduction band valleys along the C<sub>2</sub> axis of the oxygen donor defect. Recent deep level transient spectroscopy and electron paramagnetic resonance experiments made with uniaxial stress have also been explained by a ground state wave function constructed from a single pair of conduction band valleys. The relationship between the various measurements is discussed. Outstanding problems for the oxygen donor are also described. (Author abstract) 38 refs.

**095230 REMOVAL OF CARBON FROM MOLTEN SILICON.** Various processes have been proposed for the production of solar grade silicon which is not required to have the same purity as that of semiconductor grade. One of the most prominent processes is the reduction of high purity silica with high purity carbon, which yields silicon with metal impurities less than 1ppm but with several hundreds ppm of carbon. Possibilities of reducing carbon content with simple processes have been investigated in this study. The results suggest that the rate of decarburization may be determined by the rate of SiC dissolution into the silicon melt. The effects of filtering tubes was also studied. 2 refs.

**095231 PASSIVATION IN SILICON.** We summarize recent results in hydrogen passivation in silicon, and present the first comprehensive diffusion profiles, i.e. profiles in floating zone n-type and p-type vs. temperature and vs. resistivity. Domination of hydrogen diffusion by impurity trapping is clearly indicated for part of the profile in low resistivity p-type silicon. Also discussed are the current models of hydrogen passivation of dangling bonds, shallow acceptors, shallow donors and hyper-deep defects. (Author abstract) 14 refs.

**095232 THERMAL REDISTRIBUTION OF FLUORINE IN BF<sub>2</sub><sup>+</sup>-IMPLANTED SiO<sub>2</sub>/Si STRUCTURES.** Concentration profiles of fluorine is isochronal vacuum-annealed single-crystal Si and SiO<sub>2</sub>/Si structures implanted with  $2 \times 10^{15}$  111 keV <sup>11</sup>B<sup>19</sup>F<sub>2</sub><sup>+</sup> ions cm<sup>-2</sup> have been studied by the nuclear resonance broadening technique through the reaction <sup>19</sup>F(p,  $\alpha$ )<sup>16</sup>O. No loss of redistribution of fluorine was observed in either the Si or SiO<sub>2</sub>/Si samples for 30 min anneals up to 700°C. Annealing the Si targets above this temperature led to loss and redistribution (up to 80% at 1000°C) of fluorine. Annealing of the SiO<sub>2</sub>/Si samples at 900°C and above led to lower loss (10% at 1000°C) and agglomeration of the fluorine, most probably at the SiO<sub>2</sub>/Si interface. (Author abstract) 36 refs.

**095233 STUDY OF DEFECTS IN PHOSPHORUS ION-IMPLANTED SILICON.** Defects in phosphorus implanted silicon with doses from  $5 \times 10^{14}$  to  $1 \times 10^{16}$  cm<sup>-2</sup>, thermally annealed in a tube furnace at 900°C, have been studied by transmission electron microscopy. A dislocation network with regular distribution was observed for the sample with dose  $1 \times 10^{16}$  cm<sup>-2</sup>. For samples with doses  $5 \times 10^{15}$  cm<sup>-2</sup>, different density dislocation loops were observed. The formation mechanism of

the dislocations is due to the release of misfit stress under the action of thermal annealing. (Edited author abstract) 11 refs. In Chinese.

**095235 X-RAY TOPOGRAPHY STUDY OF THE EFFECTS OF  $\text{Cl}^+$  AND  $\text{F}^+$  IMPLANTATION IN SILICON ON OXIDATION INDUCED STACKING FAULTS AND DISLOCATION.** Oxidation accompanies the fabrication of almost every silicon integrated circuit device. As a consequence, crystallographic defects are frequently generated. In particular, the presence of oxidation-induced stacking faults have a deleterious effect on the electrical performance of bipolar charge-coupled imaging devices. To study this, the effect of  $\text{Cl}^+$  and  $\text{F}^+$  ion implantation on oxidation-induced stacking faults in floating zone grown silicon was investigated using double-crystal x-ray topography. Chloride ion implantation resulted in the shrinkage of oxidation-induced stacking faults after annealing at  $1200^\circ\text{C}$  in  $\text{O}_2$  atmosphere. (Edited author abstract) In Chinese 11 refs.

**095236 INVESTIGATION OF SILICIDE FORMATION FROM Nb/Si MULTILAYER FILM AND As OUT-DIFFUSION DURING  $\text{NbSi}_2$  FORMATION.** The formation of  $\text{NbSi}_2$  from Nb/Si multilayer film, its properties and the out-diffusion of implanted As atoms during  $\text{NbSi}_2$  formation were investigated. Rutherford backscattering of nine layers of silicon and eight layers of niobium evaporated alternatively on a silicon substrate. After annealing at  $900^\circ\text{C}$  for 30 minutes, the Nb/Si multilayer films became a silicide film of good quality. In comparison with the silicide formed from a single metal layer, the multilayer structure shows less As out-diffusion and loss during silicide formation. In comparison with routine  $900^\circ\text{C}$  30 minutes oven annealing for silicide formation, scanning electron beam annealing further decreases the out-diffusion and loss of implanted As atoms due to its transient annealing character. In Chinese 8 refs.

**095239 LATTICE DAMAGE, BORON DIFFUSION, AND DOPANT ACTIVATION IN  $\text{BF}_2$  IMPLANTED LAYERS.** The properties of boron-doped silicon layers obtained by ion implantation using  $\text{BF}_2^+$  molecular ions are studied with Rutherford backscattering spectrometry, transmission electron microscopy, secondary ion mass spectrometry, and with incremental sheet resistance and sheet Hall coefficient measurements by the anodic sectioning method. The implantation step is responsible for the formation of interstitial aggregates at the amorphous/crystal interface. The size of these aggregates, and hence the total number of defects involved, depends on the implant conditions, and is different for samples implanted in the two systems used (a medium current and a high current implanter). (Edited author abstract) 17 refs.

**095241 ATOMIC STRUCTURE OF DISLOCATIONS AND DIPOLES IN SILICON.** Dislocations of the  $a/2 \langle 110 \rangle$  Burgers vector lying in  $\{001\}$  and  $\{111\}$  planes in the form of cross-grids are often observed in ion-implanted and thermally annealed specimens of diamond cubic materials. In order to assess the mechanism of formation of these dislocations, we have calculated the energies and determined the atomic core structures of  $a/2 \langle 110 \rangle \{001\}$  edge dislocations and their dipoles, and of  $a/2 \langle 110 \rangle \{111\}$  dislocations in silicon by minimizing the total configurational energy. The calculations were made using Keating potentials and these results are compared with those obtained using more recent ideas. The results indicated that non-equilibrium effects must prevail during the formation of observed dislocation dipoles. (Edited author abstract) 18 refs.

**095242 TEMPERATURE AND TIME DEPENDENCE OF DOPANT ENHANCED DIFFUSION IN SELF-ION IMPLANTED SILICON.** Diffusion experiments for boron, phosphorus, arsenic, and antimony were performed in the presence of lattice defects produced by silicon ion implantation. The effects of transient enhanced diffusion were revealed by beveling and staining measurements on selectively implanted samples and by SIMS determinations of dopant profiles. The annealing of the doped implanted specimens ranged from  $700^\circ$  to  $1100^\circ\text{C}$ , the last treatment having been made by electron beam. The low temperatures allowed the following of the kinetics of the anomalous diffusion: it was ascertained that the enhanced diffusion coefficient is nearly constant until a time value is reached which decreases with the temperature increase, after which it tends gradually to the equilibrium value. (Edited author abstract) 32 refs.

Angelucci, R. (CNR, Bologna, Italy); Cembali, F.; Negri, P.; Servidori, M.; Solmi, S. *J Electrochem Soc* v 134 n 12 Dec 1987 p 3130-3134.

**095243 EFFECT OF BEAM CURRENT ON THE CRYSTAL QUALITY OF THE RESIDUAL SILICON LAYER IN BURIED NITRIDE STRUCTURE FORMED BY NITROGEN IMPLANTATION WITH A STATIONARY BEAM.** The authors demonstrate that the crystal quality of the residual silicon layer in buried silicon nitride structure produced by nitrogen implantation with a stationary beam apparently depends on the beam current. When the beam current is low (0.05–0.15 mA) and, hence, the local peak temperature during implantation is low ( $300^\circ$ – $600^\circ\text{C}$ ), the residual silicon layer is highly defective. When the beam current is sufficiently high (0.2 and 0.4 mA), albeit there is a large temperature cycling effect, a superior quality surface can be formed due to the high temperature in situ heating during implantation. 17 refs.

**095244 RESISTANCE CHANGES IN SILICON BY MeV PROTON IMPLANTATION.** Protons were implanted into the phosphorus-doped ( $6 \times 10^{13} \text{ cm}^{-3}$ ) epitaxial region of insulated gate transistors at MeV energies and doses ( $3 \times 10^{11}$ – $10^{13} \text{ cm}^{-2}$ ) in the range of those used for lifetime control in silicon power devices. Spreading resistance depth profiles were used to study changes in resistance after implantation and subsequent annealing. After implantation, the largest resistance increase occurs near the proton range; the resistance profile is similar to the expected displaced atom profile. The resistance increase is attributed to carrier compensation rather than to a decreased mobility. At a dose of  $10^{13} \text{ cm}^{-2}$  1.5 MeV protons, the resistance increase is observed to saturate. (Edited author abstract) 15 refs.

**095245 STUDY OF POSTANNEALING AND IN SITU ANNEALING OF SILICON WAFERS IMPLANTED WITH A HIGH DOSE OF OXYGEN.** The effects of postannealing and in situ annealing on the reduction of oxygen ion implantation damage in silicon wafers were investigated by means of scanning electron microscopy, Rutherford backscattering spectrometry, and transmission electron microscopy. The results of this study, which utilized an etch-pit technique in a conjunction with the SEM, showed that a high postannealing temperature ( $> 1000^\circ\text{C}$ ) was needed to effectively lower the imperfection density in the top surface region of silicon wafers. A postannealing time of 2h at a high temperature ( $> 1000^\circ\text{C}$ ) was sufficient to significantly reduce the implantation damage in the top silicon surface region. (Edited author abstract) 10 refs.

**095246 INCORPORATION OF ION-IMPLANTED ALUMINUM IN SILICON ANNEALED AT HIGH TEMPERATURES.** In this paper a case study of Al implanted in  $\langle 111 \rangle$ -Si and annealed at high temperatures ( $\geq 1200^\circ\text{C}$ ) is presented. At such high temperatures, deep junctions ( $\geq 10 \mu$ ) were easily achieved using Al as a p-type dopant. Our Al profiles for samples annealed at  $1200^\circ\text{C}$  are qualitatively similar to those reported in the literature. Precipitates of aluminum oxide having a crystalline structure were found in the implanted region and associated with the anomalous redistribution of Al observed in SIMS analysis. This is the first time that the

presence of precipitates of aluminum oxide having a crystalline structure in Al-implanted and annealed Si has been reported. 9 refs.

**095248 AI-RECOIL IMPLANTATION INTO n-TYPE Si USING DIFFERENT PRIMARY IONS.** Al/Si is probably the most widely investigated metal semiconductor structure ever examined. This work studied the effects of Al-recoil implantation into n-type Si using  $\text{Ar}^+$ ,  $\text{B}^+$  and  $\text{BF}_2^+$  as the primary ions. At different implant dosages, simulated profiles, sheet resistances, I-V curves were measured to determine the properties of the implanted surface layers. It was found that the activation of the recoiled Al was much lower compared with that of B. At low implant dosages, Schottky barriers were formed. They became p-n junctions at the higher implant dosages. Transitional properties were affected by the recombination mechanisms and damage. The  $\text{Ar}^+$ -implanted samples produced p-n junctions with somewhat inferior characteristics. (Author abstract) 10 refs.

**095249 DISTRIBUTIONS OF BORON AND PHOSPHORUS IMPLANTED IN SILICON IN THE ENERGY RANGE 0.1-1.5 MeV.** Boron and phosphorus were implanted in p-type and n-type silicon wafers in the energy range from 0.1 to 1.5 MeV. Three different methods were used to determine the distribution of the ions: SIMS, CV and NRA. The results were fitted to a Pearson IV distribution in order to extract moments for describing the distributions analytically. The projected ranges agree well with the theoretical values. Deviations are observed at higher energies. Projected range standard deviations are significantly greater than the tabulated values. The skewness clearly deviates from available tabulated data, although the same trend is observed. (Author abstract) 22 refs.

**095250 PROPERTIES OF CLUSTERED INTERSTITIALS IN ION-IMPLANTED SILICON: COMPARISON BETWEEN A MONTE CARLO SIMULATION AND X-RAY DIFFRACTION MEASUREMENTS.** In this letter a dynamical Monte Carlo method is used to calculate the strain induced in a silicon lattice by the disorder caused by implantation. The model is based on the prevailing role of clustered interstitials. Comparison with experiments shows that the disorder which survives spontaneous annealing is attributable to the few interstitial clusters formed within the cascade volume. (Author abstract) 16 refs.

Mazzoni, A.M. (Centro Nazionale Ricerche-Istituto Lab Materiali e Componenti Elettronica, Bologna, Italy); Servidori, M. *Phil Mag Lett* v 57 n 2 Feb 1988 p 85-90.

**095251 EFFECT OF A TEMPERATURE GRADI-**

**ENT ON ARSENIC DIFFUSION IN SILICON.** The effect of a temperature gradient on arsenic diffusion was investigated. Arsenic-implanted silicon wafers were subjected to temperature gradients in the order of  $100^\circ\text{C cm}^{-1}$  in a rapid thermal anneal apparatus. No measurable differences were observed in the arsenic profiles by changing the direction of the temperature gradient in the low dose ( $1 \times 10^{14} \text{ cm}^{-2}$ ) Si(111) and Si(100). The calculations agree well with measured results for the low and high dose Si(100). However, there is disagreement for the high dose Si(111). It is proposed that the defect-enhanced Soret effect, which couples arsenic diffusion flux to the heat flux in the highly disordered crystal, may cause the observed temperature gradient dependence in arsenic penetration. (Edited author abstract) 20 refs.

**095252 CONDUCTIVITY OF ION IMPLANTED AND RAPID THERMAL ANNEALED SEMI-INSULATING POLYCRYSTALLINE SILICON.** Semi-insulating polycrystalline silicon (SIPOS) films of various oxygen content have been deposited on silicon dioxide. The films were implanted with As, B, and P and were annealed with a tungsten-halogen lamp rapid thermal annealing furnace. A low temperature forming gas anneal was included as a last step. The sheet resistance was found to be a function of oxygen content of the film, ion implantation dose, type of dopant implanted, and annealing conditions. Sheet resistances could be controlled over five orders of magnitude by controlling the above parameters. Boron gave a lower sheet resistance with arsenic and phosphorus giving larger values for the same fabrication conditions. (Edited author abstract) 29 refs.

**095253  $\text{BF}_2^+$  ION IMPLANTATION IN SILICON.** In the present work we study the effect of the ion post-acceleration on the boron depth profile in  $\text{BF}_2^+$ -implanted silicon layers. Experiments show that SIMS boron depth profiles show two boron peaks: a first one, closer to the surface, is well described by a gaussian distribution, as modeled for an amorphous matrix; and a deeper second one, due to dissociated  $\text{BF}_2^+$ , is well described by a Pearson IV distribution plus exponential tail. The dissociation of  $\text{BF}_2^+$  takes place just after the mass analysis, before the post-acceleration, with an efficiency of the order of 2-5% for the DF-3000 Varian implanter; however, this result depends on the particular experimental arrangement. 12 refs.

**095255 DETERMINATION OF DOPING PROFILES FOR LOW BORON ION IMPLANTATIONS IN SILICON.** A method for determination of doping profiles from the silicon surface to the deep bulk using a high frequency C-V technique is presented. Experimental results using Ziegler's method for obtaining the profile near the surface are compared with theoretical calculations assuming Gauss type distribution and using spread-

ing resistance measurements. Doping profiles of boron implanted at 60 keV with doses in the range of  $6 \times 10^{10}$  -  $3 \times 10^{12} \text{ cm}^{-2}$  were investigated. The obtained peak value of the profile  $N(x)$  and its linear dependence on the implanted dose  $N_d$  can be used for the determination of low boron doses in p-type silicon substrates during MOS device fabrication. (Author abstract) 12 refs.

Kinder, R. (Technical Univ of Bratislava, Bratislava, Czech); Frank, H. *Solid State Electron* v 31 n 2 Feb 1988 p 265-268.

**095256 STUDY OF LATTICE DAMAGE IN ION-IMPLANTED SILICON WAFERS BY PHOTOACOUSTIC SPECTROSCOPY.** The effect of boron or phosphorus implantation on silicon wafers and the annealing behaviour of ion-implanted silicon wafers are studied by photoacoustic spectroscopy (PAS). Lattice damage induced by ion-implantation with doses  $10^{12} \text{ cm}^{-2}$  to approximately  $10^{15} \text{ cm}^{-2}$  is observed. After annealing, the residual defects in the damage region are examined. It is concluded that the rapid thermal annealing is more effective than the conventional one in removing the defects in ion-implanted layers of silicon wafers under certain circumstances. (Edited author abstract) 10 refs.

**095257 OPTICAL PROFILE ANALYSIS OF DIFFUSED AND ION-IMPLANTED SILICON.** In doping profiles used by modern semiconductor technology there are large gradients of the complex refractive index which produce significant spectra of integral optical reflectivity and transmission by internal reflection. In this case the calculus of geometrical optics approximation cannot be used. It is shown that it is possible to calculate the spatial distribution of the optical constants and the local free carrier concentration, respectively, using the matrices calculation of multilayer structures and the Drude theory. The concentration profiles which are used for as an example are present in boron diffused (surface concentration up to  $N_0 = 3.4 \times 10^{20} \text{ cm}^{-3}$ ) and ion implanted (fluence of implanted boron ions:  $N_{D,0} = 10^{16} \text{ ions/cm}^2$  at 150 keV) silicon samples. After successive isochronally annealing (700 to  $950^\circ\text{C}$ ) the implanted ions are activated as an increasing modified Gauss profile. Another aspect is the question of transmission and reflectance if the direction of wave propagation is changed in connection with the theorem of reciprocity. In agreement with theory the integral transmission is symmetrical, but the integral reflection is asymmetrical. (Edited author abstract) 14 refs.

Kessler, F.R. (Technische Univ Braunschweig, Braunschweig, West Ger); Barkow, U.; Nies, R.; Unzner, N. *Phys Status Solidi A* v 105 n 2 Feb 1988 p 627-635.

**095258 STUDY ON  $\text{Fe}^+$  IMPLANTED IN SILICON.**  $\text{Fe}^+$  implanted in silicon is studied by way of the conversion electron Moessbauer spectroscopy, together with the second ion microprobe spectroscopy, and the measurements of the electrical and optical parameters of the implanted layer. The results show that before and after low temperature annealing, the high dose of the implanted iron in silicon is concentrated in many small zones in the implanted layer rather than uniformly distributed in it. The iron is in substitutional positions in these densely concentrated zones. After low temperature annealing the iron is still in electrically inactive state. The view that Fe-Si compound phase may form after high temperature annealing is further supported by the results of ion probe analysis. (Edited author abstract) 7 refs. In Chinese.

**095259 TRANSIENT EFFECTS DURING SIMS DEPTH PROFILING WITH OXYGEN.** Before a steady state is reached in a SIMS experiment with oxygen primary ions, transient effects occur due to the build-up of an oxygen profile in the sample. We studied profiles in the

situation in which the variation of ionization yield, radiation enhanced diffusion, and radiation enhanced segregation are assumed to be the relevant process. Low energy As and Sb implantations (4 keV to 10 keV) as well as homogeneously doped wafers are studied. In the transient region attention is paid to the As or Sb ion as well as to a high intensity molecular compound (AsSiO or SbSiO). Experiments were carried out using an electron beam to irradiate the sample during sputter profiling. The changes in the profile shape with varying primary energy, oxygen partial pressure and electron beam impact conditions lead to the description of a model of the enhanced redistribution due to segregation. (Edited author abstract). 20 Refs.

**095260 MONTE CARLO SIMULATION OF ION IMPLANTATION IN CRYSTALLINE SILICON USING MARLOWE.** The Monte Carlo program MARLOWE is used to simulate ion implantation in semiconductors, i.e., boron and phosphorus implanted into crystalline silicon. Unlike most programs of its kind which require amorphous targets, MARLOWE is able to simulate ion collisions in crystalline targets. It thus provides a more satisfactory treatment of channeling and damage cascades. Simulations are performed under varying conditions and the results are compared with experiment. In addition, the effects of various parameters (beam divergence, lattice temperature, etc.) are investigated. The adequacy of the theories used in the program, in particular the treatment of inelastic losses, is evaluated, and recommendations for further development are made. Post-processors written for the program are described. (Author abstract). 17 Refs.

**095261 STUDY OF THE SHEET CONDUCTANCE PROFILES FOR RECOIL-IMPLANTED n-P T%YPE SILICON.** Recoil implantation provides an alternative means to form very shallow and highly doped surface layers. The thickness of these layers depends on the implant conditions as well as the activity of the dopant atoms. Under appropriate recoil implant conditions, very shallow surface layers could be formed. This work examined the recoil implanted sheet conductance profiles in n-Si. Both Co and Al dopants were used. The sheet conductances were measured using the standard four-point probe technique and the profiles were obtained by successive anodic oxidation and etching of the implanted layers. The data were compared with simulated results based on reported recoil dopant profiles suggested by L.A. Christel et al (1981). The sheet conductances appeared to provide a reasonable estimation of the surface carrier densities. 7 refs.

**095262 RTA PROCESS OF ARSENIC-IMPLANTED SILICON.** The RTA process with an rf induced graphite as an irradiation heat source is investigated. It is found that the complete process of RTA can be divided into two steps. When the temperature is in the range of 800-900°C, a solid phase is grown epitaxially, and then at 1000°C and higher temperatures, damages and defects are annealed out. (Author abstract). 6 Refs. In Chinese.

**095264 MODELLING OF <sup>18</sup>O TRACER STUDIES OF THE OXYGEN REDISTRIBUTION DURING FORMATION OF SiO<sub>2</sub> LAYERS BY HIGH DOSE IMPLANTATION.** The modelling of buried SiO<sub>2</sub> layer formation by high dose implantation is extended to simulate new experimental data. The experiments involved the implantation of two different oxygen isotopes (<sup>16</sup>O and <sup>18</sup>O) followed by subsequent analysis by secondary ion mass spectroscopy (SIMS) to determine the isotope distributions. Using the model, isotope depth distributions have been generated for comparison with the experimental data. For doses lower than the critical dose needed for layer formation, profiles have been calculated showing the distribution of the two isotopes. For the case where the combined dose is greater than this critical dose good agreement is found between the experimental data and the distributions calculated. Some discrepancies are apparent especially at the edges of the buried layer which originate in the non-linearity of the SIMS signals. (Edited author abstract). 17 Refs.

**095266 TWO-DIMENSIONAL MODELING OF ION IMPLANTATION INDUCED POINT DEFECTS.** An analytical model for the description of ion-implantation-induced damage profiles is presented. The model is based on extensive Monte Carlo simulations of B-, P-, As-, and Sb-implantations in Si. One-dimensional profiles are described by a Gaussian function and an exponential function joined together continuously with continuous first derivatives. The two-dimensional model has previously been developed by the authors for dopant profiles and is demonstrated to apply well to point defect distributions. Parameters have been obtained for the four ions by fitting the model to the Monte Carlo results, and they are provided in the form of tables for the energy range of 10-300 keV (for the ID model 1-300 keV). The Monte Carlo simulations are based on the binary collision approximation, the assumption of a random target, and the validity of the linear collision cascade theory. The importance of energy transport by recoils is pointed out. 23 refs.

**095267 TRANSIENT ELECTRON BEAM ANNEALING OF ARSENIC IMPLANTED SILICON.** Single crystal silicon, doped by implantation of arsenic ions (maximum concentrations between  $3 \times 10^{20}$  and

$5 \times 10^{20} \text{ cm}^{-3}$ ) was annealed by irradiation with a raster scanned beam at power density of about  $100 \text{ W cm}^{-2}$ . Arsenic redistribution and substitutionality were studied by Rutherford backscattering and channeling techniques. Sheet resistance was measured by a four-point probe. Using thermal cycles lasting about 1s, full activation with little dopant movement was observed for the higher energy implants while the best result for the 5 keV implants was 90% substitutionality. (Author abstract) 16 refs.

**095268 BURIED OXIDE FORMATION IN Si BY HIGH-DOSE IMPLANTATION OF OXYGEN.** The formation of a buried oxide film in Si by high-dose implantation of oxygen and subsequent annealing has been studied. It has been shown that this method can render good quality silicon-on-insulator with a dislocation density lower than  $10^5 \text{ cm}^{-2}$  and sharp interfaces. The microstructure after annealing was demonstrated to depend strongly on that in the as-implanted state. Silicon point defects have been argued to play an important role in the determination of the microstructure. (Author abstract) 10 refs.

**095269 OPTICAL AND COMPOSITIONAL STUDIES OF BURIED OXIDE LAYERS IN SILICON FORMED BY HIGH DOSE IMPLANTATION.** Samples of standard SIMOX material, dose  $2.4 \times 10^{18} \text{ cm}^{-2}$  at 200 keV have been examined in the as-implanted and annealed condition. The samples were prepared by wet-chemical etching with the silicon overlayer being removed first. Samples were then etched to remove the buried oxide, revealing and successively exposing the interface. These samples were then examined by ellipsometry and SIMS with an emphasis on the optical properties and compositional nature of the interfaces. Ellipsometry results indicate that a final layer of the buried oxide with refractive index 2.5 to 3 and thickness 150 to 250 Å is very resistant to the oxide etch. This may be correlated with the compositional profile of the interfacial region obtained by SIMS. The interface between the buried oxide and bulk silicon includes two layers, the first of silicon with SiO<sub>2</sub> precipitates and the second of entirely SiO<sub>2</sub>. (Author abstract) 9 refs.

## Ionization

**095270 DRIFT VELOCITY AND IONIZATION COEFFICIENT FOR HOLES IN SINGLE-VALLEY SEMICONDUCTORS.** An analytical theory has been developed for drift velocity ( $V_d$ ) and ionization coefficient ( $\alpha_h$ ) of holes in silicon. Based on Boltzmann transport equation, expressions for drift velocity ( $V_d$ ) and ionization coefficient ( $\alpha_h$ ) are derived. The theoretical approach is based on calculation of the collision operator for ionization probability, approximated by a delta function. It is observed that the values drift velocity ( $V_d$ ) and ionization coefficient ( $\alpha_h$ ) agree with experimental results for ionization length ( $l_{io} = 70 \text{ Å}$ ) and ionization energy ( $\epsilon_i = 2.5 \text{ eV}$ ). This confirms the validity of the developed theoretical model. (Edited author abstract) 19 refs.

## Magnetic Field Effects

**095272 TUNING CORRELATION AND LOCALIZATION LENGTHS WITH HIGH MAGNETIC FIELDS NEAR THE METAL-INSULATOR TRANSITION.** Various experiments at low-temperatures on Si:As in the critical regime ( $0.8 < N/N_c < 1.2$ ) near the metal-insulator transition have yielded information on magnetic-field-induced changes in the correlation and localization lengths. The measurements include magnetoresistance of metallic samples, magnetocapacitance, ac magnetocapacitance, and the field dependence of Mott variable-range hopping conduction for insulating samples. The field-induced changes in  $\xi(N, H)$  are interpreted in terms of field-induced changes in the critical density  $N_c$  and the correlation-localization-length exponent  $\nu(H)$ . The implications of the results for the Shapiro phase diagram are discussed. (Author abstract) 57 refs.

**095273 ELECTRON PARAMAGNETIC RESONANCE OF AN Fe-Fe PAIR IN SILICON.** The electron paramagnetic resonance spectrum Si-NL24, which is associated with an iron-iron impurity pair and was earlier observed in electron-irradiated silicon, was produced as a quenched-in defect spectrum. Contrary to previous work we could resolve the complete angular dependence of the spectrum and found that it has monoclinic  $I$  symmetry. Two possible atomic models with the iron atoms at interstitial sites are presented. The EPR spectrum can be described as a paramagnetic system with  $S = \frac{1}{2}$  and rather unusual  $g$ -values, as well as by  $S = \frac{5}{2}$  and  $g$ -values close to  $g = 2$ . Hyperfine interactions with two equivalent  $^{57}\text{Fe}$  nuclei could be determined. This Fe-Fe pair and the  $\text{Fe}_2$  complex are the only intermediate states in the thermal clustering process of interstitial iron which are observed in electron paramagnetic resonance. **095275 FURNACE DIFFUSION OF SI WAFERS USING SOLID SOURCE WAFERS OF VARIOUS MATERIALS.** Solid source wafer technology facilitates the production of silicon wafers in the manufacture of semiconductors. This planar diffusion source (PDS) method provides a high degree of doping uniformity with mass transport of dopant to all silicon surfaces. The process is safe and its cleanliness and reliability virtually eliminates manufacturing downtime. In use, the solid source and silicon wafers are edge stacked in furnace carriers so that each source wafer is followed by two back-to-back silicon wafers. Wafer transfer robots facilitate this stacking arrangement and automatically load wafers into the furnace. A number of solid source dopants such as multi-temperature phosphorus, boron nitride and arsenic can be used. Process specifics are described. 2 refs.

**095278 KINETICS OF OXYGEN DIFFUSION TO THE GRAIN BOUNDARY IN OXYGEN-RICH DIRECTIONALLY CAST SILICON BICRYSTALS.** The electron beam induced current mode of a scanning electron microscope has been used to measure the minority carrier recombination velocity at the depletion layer edge of the grain boundary as a function of annealing time (30-240 min) and temperature (600-900°C) in oxygen-rich directionally cast silicon bicrystals. The minority carrier recombination velocity at the grain boundary has been found to increase significantly with increasing annealing time and temperature. The grain boundary barrier potential has been determined from the zero-bias capacitance as a function of annealing time and temperature. A theoretical model has been proposed whereby the diffusivity of oxygen in silicon can be computed from the increase in grain boundary interface trap density, calculated from the grain boundary recombination velocity and barrier potential. (Edited author abstract) 16 refs.

## Mechanical Properties

**095279 STUDY OF INDENTATION ANNEALING OF (111) P-TYPE SINGLE CRYSTAL SILICON.** The indentation rosette size in (111) p-type Czochralski grown

silicon was measured as a function of annealing temperature (450 to 1100°C), time (600 to 9300 sec) and indentation load (0.147 to 2.94 N). The indentations were made with the silicon surface immersed in an electrolytic solution containing NaI with concentrations in the range of  $10^{-5}$  to  $10^{-1}$  Ml $^{-1}$ . The indentation rosette size  $<2L>$  increases with annealing time and temperature, and indentation load. The indentation rosette size has three stages as the temperature increased. The indentation rosette size increases with increasing indentation load. The concentration of NaI solution, in contact with silicon surface during indentation influenced the indentation rosette size. The maximum in rosette size is obtained in  $4 \times 10^{-4}$  Ml $^{-1}$ . 22 refs.

**095280 AVOGADRO CONSTANT - RECENT RESULTS ON THE MOLAR VOLUME OF SILICON.** The density  $\rho$  of two silicon crystals has been determined by precision hydrostatic weighing, based on very accurate solid density standards (SDSs). Densities of additional crystals were gained from density differences measured by the temperature-of-floatation method. The molar mass  $M$  of the crystals was determined by comparing the isotopic abundances against the known abundances of the National Bureau of Standards (NBS) reference material SRM 990 using activation analysis and mass spectroscopy. Combining the measured values for  $M$  and  $\rho$  leads to  $M/\rho = (12.058\,822 \pm 0.000\,013)$  cm $^3$ /mol. With the known volume of the unit cell the following value for the Avogadro constant was calculated:  $N_A = (6.022\,137 \pm 0.000\,007) \times 10^{23}$  mol $^{-1}$ . 18 refs.

### Microscopic Examination

**095283 MEASUREMENTS OF SMALL ELASTIC STRAINS USING ELECTRON CHANNELING PATTERNS.** A silicon single-crystal slab 0.15 mm in thickness was bent to produce small, nonuniform surface strains of the order of 0.2 percent. The electron channeling patterns were observed in a JSM 840 SEM (scanning electron microscope) at an accelerating voltage close to 25 kV. Proper choice of the triangles formed by intersecting channeling lines of zero-order and of higher-order Laue zones allows one to measure the changes in their dimensions caused by imposed strain. It was estimated that the lower limit of detectable elastic strain is close to 0.1 percent. The possibilities of using this method for estimation of the average elastic strains in thin epitaxial layers are discussed. (Author abstract) 16 Refs.

**095286 MORPHOLOGY AND ELECTRONIC PROPERTIES OF PHOSPHORUS-DOPED HYDROGENATED AMORPHOUS AND MICROCRYSTALLINE SILICON DEPOSITED BY DC DISCHARGE IN SiH<sub>4</sub>/PH<sub>3</sub>.** n-Type Si:H films have been prepared by DC discharge decomposition of SiH<sub>4</sub>/PH<sub>3</sub> gas mixtures to investigate the effects of the discharge current density ( $J_{DC}$ ) and voltage ( $V_{DC}$ ) on film structure and dark electrical transport characteristics. Examination of the resulting Si:H films by transmission electron microscopy (TEM) indicates a discernible microstructure that depends on the discharge parameters. Film growth can be interpreted in terms of the effect of the deposition parameters on nucleation and surface diffusion. Increasing  $V_{DC}$  enhances the nucleation density resulting in a homogeneous, fine-grained structure that is largely amor-

phous. In contrast, increasing  $J_{DC}$  enhances surface mass transport, resulting in a two-phase structure consisting of crystallites, as large as 1000 Å in diameter, interconnected by an amorphous tissue. For a given impurity level, the resulting electrical transport characteristics are correlated with microstructure; higher dark conductivities are associated with deposition conditions that enhance microcrystallization. (Author abstract) 23 Refs.

### Noise, Spurious Signal

**095287 SPATIAL CORRELATION MEASUREMENTS OF 1/f NOISE IN SEMICONDUCTORS.** One of the proposed models for 1/f noise, thermal fluctuations theory, involves a diffusive mechanism which implies spatial correlation of the fluctuating quantity within a frequency-dependent correlation length. In order to test this prediction, we have performed spatial correlation measurements on p-type conductive diffused strips of silicon at temperatures between 20 and 295 K. The frequency span was from 10 Hz to 10 kHz. We have not found any correlation between the 1/f fluctuations in two different segments of the strip separated by 2.5 mils, making diffusion mechanism an unlikely origin of the noise. (Author abstract) 11 refs.

### Nondestructive Examination

**095288 NONDESTRUCTIVE NONCONTACT TESTING OF SILICON WAFERS AND DEVICES MADE FROM THEM BY INDUCTIVE CHARGE EMF IN A SCANNING ELECTRON MICROSCOPE.** Information concerning local electric nonuniformities and the electrophysical parameters of the original semiconductor wafers and structures, upon which the functional characteristics of integrated circuits made from them ultimately depend, is very important. The problem of developing noncontact and nondestructive methods for testing the raw materials and fabricated elements of semiconductor devices is real. We will examine the possibilities and a new method of investigating local electrophysical parameters in the surface and subsurface layers of silicon structures based on scanning the change in surface deflection of the zones in the charge states at the radiation points and the surface barrier (inductive charge) emf associated with them. 8 refs.

**095289 DETERMINATION OF THE THICKNESS AND OPTICAL PROPERTIES OF AMORPHOUS SILICON FILM BY TRANSMISSION SPECTRA.** The thickness  $d$  and optical constants  $n$ ,  $k$  of amorphous silicon film have been determined simultaneously by transmission spectra. The accurate formulae for transmittance and reflectance as well as the detailed processes are given. The optical properties of GD-grown amorphous silicon films are studied. (Author abstract) In Chinese. 9 refs.

Li, Guoguang (Fudan Univ, China); Yang, Henqing; Huang, Jiaming; Chen, Junyi; Zong, Xiangfu. *Hongwai Yanjiu A-Ji* v 6 n 5 1987 p 321-328.

**095290 TEMPERATURE DEPENDENCE OF THE OPTICAL DISPERSION PARAMETERS IN Si AND Ge.** In Si and Ge, the optical dispersion parameters (single-oscillator energy  $E_0$ , dispersion energy  $E_d$  and bond energy gap  $E_g$  developed by Wemple and S.H. DiDomenico, and M. Phillips) have been analyzed in the temperature range 100-300 K using data obtained by H.

W. Icenogle et al.  $E_0$  and  $E_g$  exhibit a very small temperature dependence in both materials. The thermal coefficients of the dispersion energy,  $dE_d/dT$ , have opposite signs (Si,  $-41.9 \times 10^{-4}$  eV K<sup>-1</sup>; Ge,  $+37.7 \times 10^{-4}$  eV K<sup>-1</sup>). (Author abstract) 7 refs.

Toyoda, T. (Nippon Mining Co, Toda, Jpn). *Phil Mag Lett* v 55 n 3 Mar 1987 p 143-146.

**095291 OPTICAL ABSORPTIVITY OF ION-BEAM IRRADIATED SILICON.** Single-crystal layers of silicon on sapphire have been irradiated with Ne and Kr ions at room temperature. The concomitant changes in optical absorption have been measured as a function of photon energy. The absorptivity of the amorphized silicon is about one order of magnitude higher as compared to the crystalline state in the photon energy interval of 1.5-3 eV. This is sufficient for generating optical patterns of high contrast by irradiation of selected parts of the wafer. (Author abstract) 14 refs.

**095292 CARS PROBING OF THE Si RAMAN MODE TRANSFORMATION DURING STRONG PICOSECOND PULSED-LASER IRRADIATION.** We report on picosecond coherent anti-Stokes Raman scattering (CARS) probing of the Si optical phonon spectrum transformation during picosecond pulsed-laser irradiation. CARS spectra were obtained in reflection at various laser fluences up to melting. The observed spectrum broadening is theoretically explained in terms of phonon heating and laser-induced mechanical stress build-up on a time scale of 10 ps. (Author Abstract) 9 refs.

**095293 OPTICALLY INDUCED CHANGES IN THE SUB-BAND GAP ABSORPTION OF HYDROGENATED AMORPHOUS SILICON.** Measurements of infrared absorption in thin (120 nm) films of amorphous hydrogenated silicon subjected to light soaking were performed by Fourier transform infrared spectroscopy. Light exposure increased absorption in the region 0.3 to 0.4 eV but reduced it between 0.40 and 0.43 eV. These effects, which were room temperature annealable, indicate that at least two kinds of electronic states are involved. (Author abstract) 8 refs.

**095294 DEPENDENCE OF THE PHOTOLUMINESCENCE FATIGUE ON THE ILLUMINATION TEMPERATURE FOR a-Si:H.** Effects of strong illumination at temperatures between 8 K and room temperature on the photoluminescence intensity in a-Si:H were measured between 8 K and 100 K. The photoluminescence fatigue is more prominent by illumination at 8 K than at temperatures above 50 K. This result appears to contradict the usually accepted mechanism of the photo-degradation. Creation of two kinds of defects by illumination is proposed to solve the contradiction. (Author abstract) 19 refs.

**095295 FATIGUE AND LOW TEMPERATURE SELF-RECOVERY OF PHOTOLUMINESCENCE IN a-Si:H.** During a short exposure at 80 K it was observed that the photoluminescence (PL) intensity decreases by 14-50% of its original value to a steady-state by a  $t^{1/3}$  time process. The fatigued PL intensity spontaneously returns to its starting value if the excitation light is turned off and the sample is kept in the dark for a few minutes at the original temperature. The dark recovery

shows an exponential time dependence with time constants of about one minute. The fatigue of PL depends on the substrate temperature during preparation and has a maximum at  $T_S = 300^\circ\text{C}$  (50% fatigue). The results are interpreted by the transition: weak bonds  $\leftrightarrow$  dangling bonds. (Author abstract) 9 refs.

## Order-Disorder

**095299 ORIENTATIONAL DISORDER IN AMORPHOUS SILICON PROBED BY XANES (X-RAY ABSORPTION NEAR EDGE STRUCTURE).** The difference between the K-edge XANES spectra of crystal and amorphous silicon is discussed. We show that the multiple scattering signal gives a large contribution to the total absorption in crystalline silicon in an energy range of about 70 eV. The double scattering term probing the triplet distribution function gives the major contribution to the XANES. We show that the difference between the crystalline and amorphous absorption spectra is due mainly to the crystalline multiple scattering signal which is quenched in the amorphous spectrum. The suppression of the signal due to the triplet distribution function in the amorphous silicon is assigned to the large orientational disorder. (Author abstract) 23 refs.

**095300 KINETICS AND MECHANISM OF THE ELECTROCHEMICAL FORMATION OF POROUS SURFACE LAYERS ON SILICON IN HYDROFLUORIC ACID. SPECIFIC KINETIC FEATURES OF POROUS-LAYER FORMATION ON n- AND p-TYPE SILICON.** In the region of linear kinetics in the dark, the rate of formation of the porous layer (PL) is 6-7 times higher on the n-type than on the p-type material. The amount of silicon dissolved increases linearly with time for both types, under these conditions, but the dissolution rate of the p-type material is 1.2-1.3 times higher than that of the n-type material. The differences in the structure and formation kinetics of the porous layer and in silicon dissolution arise from the fact that, in the case of p-type material, PL formation occurs on account of silicon oxidation to compounds of lower valency, while at n-type material a mixed dissolution mechanism is operative which involves a predominant oxidation to the tetravalent state. (Author abstract) 19 refs.

**095305 WET HYDROGEN OXIDATION IN THE PRESENCE OF MOLYBDENUM AND TUNGSTEN FOR VLSI APPLICATIONS.** Oxidation of Si in the presence of Mo or W can be performed in an atmosphere of  $H_2$  with a low partial pressure of  $H_2O$ . A pyrogenic version of this process was established. The quality of oxide grown by this method is found to be comparable to that of dry thermal oxides. However, Si oxidation is observed to occur underneath Mo and W layers on the Si surface, as well as under Mo and W layers capped with phosphosilicate glass. Additionally, oxidation is observed within several microns of the periphery of  $Si_3N_4$ -capped Mo and W layers, leading us to conclude that modification of the gate structure or material is required to make WHO practical for source/drain reoxidation in refractory Mo or W gate VLSI. (Author abstract) 7 refs.

**095306 CHARGE TRAPPING IN OXIDE GROWN ON POLYCRYSTALLINE SILICON LAYERS.** Shifts in tunneling I-V characteristics are used to study electron trapping in oxides thermally grown on silicon layers deposited in both amorphous and polycrystalline phases. The electron trapping resulted from charge injection by tunneling from either the bottom or top electrodes of capacitors constructed of two deposited silicon layers separated by thermal oxide. It is observed that upon injection from the top electrode, the resulting trapped-charge centroid is located close to the middle of the oxide layer. On the other hand, injection from the bottom electrode results in an apparent trapped-charge centroid which is located near the bottom silicon-oxide interface. (Edited author abstract) 28 refs.

**095307 BLOCKING OF SILICON OXIDATION BY LOW-DOSE NITROGEN IMPLANTATION.** The oxidation characteristics of silicon implanted with a low dose of nitrogen ( $1.3 \times 10^{15} \text{ cm}^{-2}$ ) have been studied for dry oxidation conditions at  $1020^\circ\text{C}$ . The wafers were subjected to a pre-oxidation annealing. Complete inhibition of the oxide growth occurs in the initial stage of oxidation, while the oxidation rate for prolonged oxidation is identical to that for pure silicon. The oxidation resistance increases with the implantation dose. The resistance is attributed to the formation of a nitrogen-rich surface film during annealing. This layer, which consists of only a few monolayers, is presumably composed of oxynitride. The electrical characteristics of MOS capacitors formed on implanted wafers show that the interface state density is not significantly increased by the low-dose N implantation. **095308 ANODIC OXIDATION OF HYDROGENATED AMORPHOUS SILICON AND PROPERTIES OF OXIDE.** Anodic oxidation in an ethylene glycol solution of potassium nitrate is shown to be capable of forming uniform amorphous  $SiO_2$  layers on hydrogenated amorphous silicon (a-Si:H) films at room temperature at a rate of 5.5 Å/V up to the maximum thickness of about 2500 Å. The process is stable, reproducible, and electrically controllable. The oxidation process and the properties of the anodic oxide films are described, and a detailed comparison is made with the anodization of single-crystal silicon. The anodization accompanies electroluminescence. The effect of illumination of the anode and the behavior of luminescence from the anode

are discussed in detail in an attempt to clarify the electrical behavior of the anode during anodization. (Edited author abstract) 28 refs.

**095312 GROWTH OF NATIVE OXIDE ON SILICON.** R.J. Archer has described the growth of a film on silicon at room temperature in air. F. Lukes and S.I. Raider et al. have also studied the growth of films at room temperature. With the shrinking of silicon device dimension, there is renewed interest today in the mechanisms of the growth of thin oxides. In thermal oxides, the concept of an abrupt interface between silicon and silicon dioxide has received general acceptance. This paper describes an experiment similar to that of Archer or Lukes but notes the apparent step growth in the formation of the native oxide on silicon. It is shown that the native oxide grown on a clean silicon substrate at room temperature tends to form one layer at a time. The layer thickness measured is compatible with that calculated for a monolayer of oxide. 10 refs.

**095313 ANALYSIS OF RAPID DRY OXIDATION OF SILICON.** By analyzing the most recent models on rapid initial oxidation and the experimental data at low temperatures we prove unambiguously that neither enhanced nor retarded oxygen diffusion nor any kind of additional oxygen transport flux can account for anomalous initial regime of silicon dry oxidation. The rapid growth is mainly due to the enhanced oxygen solubility and partly to the enhancement of the reaction rate constant  $k_p$ . We argue that the reaction rate depends linearly on the oxygen solubility for low solubilities

pertinent to dry oxidation but that it saturates at high solubilities characteristic for the wet oxidation. (Author abstract) 12 refs.

**095315 EXOELECTRON EMISSION OF THERMALLY OXIDIZED SILICON.** The current methods of production of semiconductor devices and integrated circuits are based on the formation of a dielectric film on the surface of the crystal. The authors examine the effect of preliminary machining of the surface of single crystal silicon with subsequent oxidation in various conditions on the extent of thermally stimulated exoemission and its relation with the structure of the surface layer and defectiveness of the oxide film. They reach the following conclusions: (1) The method of exoelectron emission yields additional information on the quality of the grown oxide and also on the number of defects in it. (2) The increase of the density of the defects in the oxide increases the concentration of the emission-active centres and, consequently, the intensity of exoemission. (3) Mechanical treatment of the surface of silicon preceding the oxidation process has a strong effect on the defectiveness of the oxide and the intensity and nature of thermally stimulated emission. 6 refs.

**095316 GENERATION-ANNEALING OF OXIDE AND INTERFACE TRAPS AT 150 AND 298 K IN OXIDIZED SILICON STRESSED BY FOWLER-NORDHEIM ELECTRON TUNNELING.** Generation and thermal annealing of oxide and interface traps at 150 and 298 K are investigated by Fowler-Nordheim electron tunneling stress. Experiments indicate that the generation rate of positive oxide changes is higher at 150 than 298 K. This could be accounted for by the higher density of energetic electrons in the oxide and at gate/oxide interface at lower temperatures due to the larger electron-phonon scattering mean free path. The annealing rates of interface traps and negative oxide traps are higher at 298 than 150 K. The higher annealing rate of the interface traps by hydrogen at higher temperatures could be interpreted by the larger hydrogen arrival rate at the interface due to the larger hydrogen diffusivity in the silicon dioxide at higher temperatures. The higher annealing rate of negative oxide traps at higher temperatures is attributed to a higher emission rate of electrons trapped at the shallow neutral electron traps at higher temperatures. (Author abstract) 29 refs.

**095318 MICROWAVE-DISCHARGE PLASMA OXIDATION OF SILICON IN A CUSP MAGNETIC FIELD.** The role of oxygen radicals and ions in the plasma oxidation of silicon is investigated using microwave-discharge oxygen plasma ignited in a cusp magnetic field. The cusp magnetic field forces streaming plasma to stop its progress resulting in a plasma boundary formation. Probe measurement of argon plasma reveals that the original plasma density of  $2 \times 10^{10} \text{ cm}^{-3}$  decreases to one-third,  $6 \times 10^9 \text{ cm}^{-3}$ , across the boundary. Thus, the cusp magnetic field achieves an oxygen plasma with fewer ambient charged particles. However, it is found that oxide growth rate on silicon does not change across the boundary. (Edited author abstract). 14 Refs.

**095319 KINETICS OF THE ROOM-TEMPERATURE AIR OXIDATION OF HYDROGENATED AMORPHOUS SILICON AND CRYSTALLINE SILICON.** An X-ray photoelectron spectroscopy determination of the room-temperature air oxidation of both hydrogenated amorphous silicon and crystalline silicon has shown that the log-log (complex order) kinetics depend on the method of surface preparation. For HF-etched surfaces, the slope is identical with those measured at significantly higher temperatures (about 1000°C). For Ar-etched surfaces, the structural damage thereby incurred gives significantly higher rates. (Author abstract). 20 refs.

**095320 TWO-DIMENSIONAL THERMAL OXIDATION OF SILICON - II: MODELING STRESS EFFECTS IN WET OXIDES.** The authors propose that the stress from two-dimensional oxide deformation affects the kinetic parameters in the Deal-Grove model. In particular, the viscous stress associated with the nonuniform deformation of the oxide is identified as the fundamental force of retardation. In this model, the stress normal to the Si-SiO<sub>2</sub> interface reduces the surface reaction rate in both convex and concave surfaces, whereas the stress in the bulk of the oxide (compressive for concave and tensile for convex surfaces) is responsible for the thinner oxides on the concave structures. The model is described by a simplified mathematical formulation made possible by the symmetry in cylindrical structures. Comparisons with experimental data, possible applications, and limitations of the model are also discussed. 33 refs.

Kao, Dah-Bin (Stanford Univ, CA, USA); McVittie, James P.; Nix, William D.; Saraswat, Krishna C. *IEEE Trans Electron Devices* v 35 n 1 Jan 1988 p 25-37.

**095321 THERMAL OXIDATION OF SILICON: NEW EXPERIMENTAL RESULTS AND MODELS.** Most studies of Si oxidation commence with a discussion of the linear-parabolic oxidation model developed by a number of workers in the 1960's. The limits of the model are pure diffusion of oxidant for thick SiO<sub>2</sub> films and a surface reaction limitation for thin films. The steady state picture of this series reaction scheme is discussed and used to explain new experimental results. New data relevant to Si oxidation is presented on the following subjects: five orientations of Si; photonic excitation; intrinsic film stress; silicide oxidation. The role of electrons on the

oxidation kinetics is elucidated. A thermionic emission model for the initial stages of oxidation is proposed. (Author abstract) 44 refs.

Irene, Eugene A. (Univ of North Carolina, Chapel Hill, NC, USA); Ghez, R. *Appl Surf Sci* (1985) v 30 n 1-4 Oct II 1987, INFOS 87: Proc of the Fifth Int Conf on Insul Films on Semicond, Louvain, Belg, Apr 13-15 1987 p 1-16.

**095322 EFFECT OF SILICON SURFACE CLEANING PROCEDURES ON OXIDATION KINETICS AND SURFACE CHEMISTRY.** The effect of surface cleaning procedures on the kinetics of thermal oxide growth on silicon is presented. The goal is to relate the properties of the cleaned surface (composition, chemistry, impurity content) to the changes in oxide growth mechanisms. Experimentally, silicon (100) wafers were given different variations of an RCA clean, and then oxidized in dry  $O_2$  at 900°C producing oxides with thicknesses between 170 and 3900 Å. The results, in general agreement with earlier studies, show that the percentage difference in thickness is strongly dependent on oxide thickness. The data, which are explained in terms of the predictions of a linear-parabolic and a parallel oxidation model suggest that the surface cleans do not alter the diffusion of molecular oxygen in the oxide. Auger analysis of the surfaces shows that there is a substantial carbon contamination on the HF stripped wafer which is considerably reduced after a 5 min  $N_2$  anneal. (Author abstract) 17 refs.

**095323 HIGH TEMPERATURE REACTION AND DEFECT CHEMISTRY AT THE  $Si/SiO_2$  INTERFACE.** The generation of structural and electrical defects in  $Si/SiO_2$  structures upon high temperature annealing by the oxide decomposition reaction  $Si + SiO_2 \rightarrow 2SiO$  has been studied using scanning electron microscopy (SEM) and ramped current-voltage measurements. The  $SiO$  decomposition is nucleated at crystalline defects in the substrate and results in the formation of voids in the oxide. The voids grow laterally with annealing time, independent of the nature of the defect. Prior to the formation of physical voids in the oxide, defects become electrically active, leading to low field dielectric breakdown. The breakdown degradation is prevented when the  $O_2$  pressure in the annealing ambient is sufficient to reverse the decomposition reaction by reoxidizing the  $SiO$  product at the interface. (Author abstract) 9 refs.

**095324 CONSTANT CURRENT VERSUS CONSTANT VOLTAGE PLASMA ANODIZATION TECHNIQUES.** In this paper a comparison is made between two basic techniques of plasma anodization, i.e. constant current and constant voltage methods. The comparison is based on new mathematical-physical models of both plasma anodization techniques, in which the condition of oxide growth during the process is expressed in terms of fluxes (oxygen ions and electrons) and/or voltages. Detailed analysis of these parameters, their changes during the oxide growth and their comparison enabled the confirmation of some of the experimentally observed effects and to predict others, unnoticed until now. Based on this analysis it is concluded that the oxide growth during the constant current plasma anodization is not only easier to be monitored and controlled, but also should result in much better anodic oxide electrophysical properties, their better control and repeatability. (Author abstract) 5 refs.

**095325 OXIDATION OF SILICON IN THE AFTERGLOW OF MICROWAVE INDUCED PLASMAS.** In this work the influence is described of various experimental parameters on the oxidation process of silicon in the afterglow of microwave induced plasmas in oxygen/argon mixtures. It was found that the oxidation is independent of the flow velocity of the reagents and of the wafer position in the fast flow reactor. By a chemical titration technique it is shown that oxygen atoms ( $^3P$ ) are the major oxidation precursors. They also form the explanation for the observed effect of the plasma composition and the reactor pressure on the silicon oxidation rate. Additionally, chlorine has only a minor effect on the oxidation rate which can be explained on the basis of a kinetic mechanism for the chlorine transformation. (Author abstract) 10 refs.

Vinckier, C. (KU Leuven, Louvain, Belg); Coeckelberghs, P.; Stevens, G.; De Jaegere, S. *Appl Surf Sci* (1985) v 30 n 1-4 Oct II 1987, INFOS 87: Proc of the Fifth Int Conf on Insul Films on Semicond, Louvain, Belg, Apr 13-15 1987 p 40-46.

**095326 EFFECTS OF LOW TEMPERATURE ANNEALING ON THE ELECTRICAL PROPERTIES OF PLASMA GROWN OXIDES.** The effects of low temperature annealing on the electrical properties of plasma grown oxides have been investigated. In conjunction with a trichloroethylene/oxygen plasma it is found that plasma oxides with good electrical properties can be obtained at annealing temperatures below 600°C. (Author abstract) 8 refs.

**095327 SILICON OXIDATION.** Today's VLSI technology is to a large extent based on the excellent properties of thermally grown silicon dioxide layers.  $SiO_2$  is used as gate dielectric in MOS devices, as implantation or doping mask, and for device isolation purposes. This paper focuses on the mechanisms and kinetics of thermal oxidation. Various oxidation techniques are reviewed and the properties of the oxides are discussed. It is emphasized that thermal oxidation of the silicon strongly affects the properties of the underlying silicon bulk material. Phenomena like oxidation-enhanced diffusion and oxidation-induced stacking faults are explained, and other silicon dioxide properties important for VLSI applications are reviewed. (Edited author abstract) 113 refs.

## Phase Transitions

**095328 EFFECT OF SPIN-ORBIT INTERACTION ON THE METAL-INSULATOR TRANSITION IN DOPED SILICON.** We show that in disordered metallic systems, spin-orbit interactions lead to the existence of two metallic phases separated in temperature. The low-temperature metallic phase arises from spin-orbit interactions. The crossover temperature is proportional to  $(Z-Z')^2$  ( $Z$  is the atomic number of the donor and  $Z'$  that of the matrix) and is expected to be observable for donors with large atomic numbers. The presence of two metallic phases implies two mobility edges, existing at different temperatures, and affecting the conductivity when the Fermi energy  $E_F$  lies below the mobility edge  $E_c$ . We thus predict anomalies in the conductivity in this range of concentration, consistent with the measurements of A.P. Long and M. Pepper on Si:Sb. (Author abstract) 16 refs.

**095329 CHARACTERIZATION OF a-Si:H PHASE TRANSFORMATION AND CRYSTALLIZATION BY ISOTHERMAL ANNEALING.** Hydrogenated amorphous silicon (a-Si:H) thin films have been prepared by plasma-enhanced low-pressure chemical vapor deposition (PE-LPCVD) from monosilane ( $SiH_4$ ) in hydrogen carrier gas. The variation of electrical conductivity with time at various isothermal annealing conditions have been used to study the phase transformation and crystallization kinetics. For the first time, it has been observed that the drop in the electrical conductivity in the early annealing stage is caused by hydrogen out-diffusion with different activation energies under various substrate temperatures. Transmission electron microscope (TEM) diffraction patterns, which directly measure crystallization, were also obtained. Furthermore, perpendicular crystallization rates for different activation energies under various substrate temperatures have been obtained. An empirical model to explain the phase transformation and crystallization kinetics of hydrogenated amorphous silicon thin films has been proposed. (Author abstract) 41 refs.

**095330 ROLE PLAYED BY MECHANICAL STRESSES AND ELASTIC WAVES IN STRUCTURAL TRANSFORMATIONS IN CRYSTALS IN ION BOMBARDMENT AND SUBSEQUENT ANNEALING.** The authors present experimental data on the effect of static and dynamic elastic fields on the nature of structural transformations taking place in the subsystem of defects on single crystal and epitaxial silicon in irradiation with ions of medium energy and in postimplantation annealing. The results show that these effects can be explained on the basis of the considerations regarding the mechanism of interaction between the defects and target atoms with the stress field as a collective process in which a relatively large number of elementary defects and atoms take part. (Author abstract) 16 refs.

Photoconductivity See Also ELECTRODES, ELECTROCHEMICAL—Chemical Modification.

**095331 PHOTOCONDUCTIVE CHARACTERISTICS AND STABILIZATION OF HYDROGENATED AMORPHOUS SILICON FILMS.** This paper describes the changes in the photoconductive characteristics under elevated environmental conditions and presents a stabilizing method of hydrogenated amorphous silicon (a-Si:H) thin films. a-Si:H is decomposed from silane in a PCVD (Plasma Chemical Vapor Deposition) apparatus. The results of high-temperature and high-humidity storage tests reveal that the photocurrent increased by about two orders of magnitude over the initial value, followed subsequently by a gradual decrease. The characteristics were stabilized through coating the film surface with a silicon nitride film deposited at room temperature by ECR (Electron Cyclotron Resonance) plasma CVD. (Edited author abstract) 13 refs.

**095333 PHOTOCONDUCTIVE a-Si:H WITH DOMINANT MONOHYDRIDE BONDING PREPARED BY DC-MAGNETRON SPUTTERING.** A description is given of a dc-magnetron sputtering apparatus used for deposition of hydrogenated amorphous silicon (a-Si:H) by reactive sputtering in an argon/hydrogen discharge. The physical properties of the deposited a-Si:H films are determined by measuring the photo and dark conductivity, the Tauc gap, the IR absorption and by ESR and RBS measurements. The influence of the main deposition parameters (hydrogen partial pressure, dc-power) on the film properties is discussed. The films reveal a minimal value of dark conductivity of  $\sigma_D = 10^{-11} (\Omega\text{cm})^{-1}$  and a four decade higher photoconductivity even for samples prepared at growth rates of 7  $\mu\text{m}/\text{h}$ . In all films the hydrogen is predominantly bound in monohydride complexes (Si-H). (Author abstract). 19 Refs.

**095334 TRANSFERABILITY OF TIGHT-BINDING PARAMETERS: THE SiN CASE.** We show that an alternative and more realistic procedure of tight-binding parametrization of 'host-impurity' interactions in the impurity problem is to take that one from the interactions of 'host-impurity perfect solid' (if any) followed by an appropriate scaling with the distance. We use this idea in the on-center Si:N case, taking the Si-N interactions from the tight-binding parametrization of  $\text{Si}_3\text{N}_4$  perfect crystal, using the  $d^{-2}$  scaling law to transfer the interactions to the impurity problem. This procedure can be useful to treat the distorted N impurity and suggestions are made to extend it to other impurity problems. (Edited author abstract) 18 refs.

**095335 SPHERICAL WAVE EXAFS ANALYSIS OF THE SILICON K-EDGE X-RAY ABSORPTION SPECTRUM.** The silicon K-edge EXAFS (extended X-ray absorption fine structure) spectrum has been analyzed by spherical wave formalism. The agreement between the experimental EXAFS spectrum in the energy range above 50 eV beyond the K-threshold and the theoretical one has been obtained using experimental values of the mean free path and of the different Debye-Waller factors for each shell. Seven shells around the absorbing atom have been considered in the calculation, but the amplitude due to the distant shells decreases rapidly with the distance, and above 80 eV only the contribution of the first three shells is important. We show that the single scattering contribution  $\chi_2(k)$  using the spherical wave approach can explain the experimental  $\chi(k) = (\mu(k) - \mu_0(k))/\mu_0(k)$  spectrum only above 50 eV. At lower energies there are strong multiple scattering effects and it is necessary to take account of other terms  $\chi_n(k)$  (with  $n > 2$ ) of given expansion. (Edited author abstract) 26 refs.

**095338 TUNNELING SPECTROSCOPY OF SURFACE AND BULK LANDAU LEVELS IN Si(001) ELECTRON ACCUMULATION LAYERS.** Magneto-oscillations in the tunneling characteristics of Ti/SiO<sub>2</sub>/n-Si(001) junctions with accumulated Si surface reflect the Landau-level structure of the  $E_0$  and  $E_1$  subbands and of bulk electrons belonging to the [100] and [010] valley pairs. The result is the effective cyclotron masses of the subbands and the principal masses of the bulk ellipsoids. (Author abstract) 19 refs.

Kunze, U. (Technische Univ Braunschweig, Braunschweig, West Ger). *Solid State Commun* v 64 n 10 Dec 1987 p 1325-1328.

**095339 CALCULATION OF THE OPTICAL PROPERTIES OF THE ISOLATED DANGLING BOND IN SILICON.** The optical ionization cross section for transitions between the level  $\epsilon(0, +)$  of the isolated silicon dangling bond and the valence band is calculated. Comparison with experiment shows that the purely electronic contribution has the correct order of magnitude. It is demonstrated that its shape can be accurately described by including the broadening due to the electron-lattice interaction with a Franck-Condon shift of 0.3 eV. The predicted correlation energy (0.65 eV) and localization of the wave function are consistent with experiment. (Edited author abstract) 28 refs.

Petit, J. (CNRS, Lille, Fr); Lannoo, M.; Allan, G. *Solid State Commun* v 60 n 11 Dec 1986 p 861-865.

**095340 AMORPHOUS SILICON.** We point out the qualitative features of amorphous silicon, particularly in relation to the crystalline form. The gap states of amorphous silicon are dealt with. The quasi-continuous distribution of such localized states in the band-gap region makes amorphous semiconductors substantially different from their crystalline counterpart. These localized states affect significantly the electrical and optical properties of amorphous silicon. The authors treat the structure and the growth kinetics of amorphous silicon, particularly a-Si:H. Photoinduced effects are surveyed, particularly on conductivity and on luminescence, from the current physics and application points of view. 181 refs.

**095341 CALCULATION OF THE ISOTOPE FREQUENCY SHIFTS OF LOCAL MODE CAUSED BY INTERSTITIAL OXYGEN IN SINGLE CRYSTAL SILICON.** A calculation of the isotope frequency shifts of local mode caused by interstitial oxygen in silicon is presented by using a 9-atom cluster model based on the force constant approach. We find that the calculated result is not better than that of a single Si<sub>2</sub>O molecular model. Even if the effects of noncentral force and local distortion of lattice are taken into account, the result is still not satisfactory. In order to obtain the best fit with the experimental isotopic shifts, it is necessary to introduce the variation of the Si-O force constant with the different

isotopes. It turns out that the Si-O force constant increases with increasing the mass of silicon atom but decreases with increasing the mass of oxygen atom. (Edited author abstract) 13 refs.

**095342 DEEP LEVEL INVESTIGATION OF N-DOPED FZ Si CRYSTALS.** The deep levels related to nitrogen in N-doped FZ Si crystals were studied by DLTS. A level located at  $E_c - 0.57$  eV related to nitrogen was observed besides the two levels,  $E_c - 0.20$  eV and  $E_c - 0.28$  eV, observed by others. After annealing at 400°C for 0.5 hr, the three levels vanished and three new levels related to nitrogen were formed. They were located at  $E_c - 0.17$  eV,  $E_c - 0.37$  eV and  $E_c - 0.50$  eV. Their annealing behavior was studied. (Author abstract) In Chinese. 6 refs.

**095344 MELTING TEMPERATURE OF AMORPHIZED SILICON HEATED BY NANOSECOND LASER RADIATION.** The optical pyrometry technique for measuring the melting temperature of an amorphized silicon (a-Si),  $T_{ma}$  was applied. Values of  $T_{ma}$  given in the literature differ by 200 to 300 K. It is found that a-Si melts at a temperature which is only about 200 K lower than  $T_{mc}$  and not 500 K as was considered earlier. Therefore, homogeneous initiation of the solid phase in the metastable melt is hardly probable and can be neglected in considering the pre-history of formation of the fine-grained polycrystal. 15 Refs.

## Plasmas

**095345 PICOSECOND TIME-RESOLVED DETECTION OF PLASMA FORMATION AND PHASE TRANSITIONS IN SILICON.** Picosecond time-resolved reflectivity and transmission changes have been measured to study the electron-hole plasma formation and phase transitions in silicon, induced by 0.53  $\mu\text{m}$ , 30 ps laser pulses. The experimental results provide evidence of ultrafast energy transfer from the laser pulse to the lattice and of lattice heating and phase transition within a time less than 30 ps. It has been pointed out that Auger recombination can limit the increment of electron-hole plasma density. Some electron-hole plasma parameters under high excitation are deduced from the experimental data. (Author abstract) 9 refs. In Chinese.

**095347 AUTOMATED POLISHING SYSTEM.** The Model 372 polisher is a fully automated, cassette-to-cassette machine that operates under full computer control. In this manner, all operator-related variables are eliminated from the process. By carefully controlling polishing temperatures, pressure, and surface speeds, flat, uniform, haze-free wafers can be produced. The machine can not only be used for conventional preparation of substrate materials, but also has applications in the production of high density packaging systems and state-of-the-art integrated circuit production. The polisher is suited for both production quantities and small lot sizes. A capability for water reclaim, or rework from batch processes, can result in increased process yields.

**095348 SELECTIVE MASKING EFFECTS OF WO<sub>3</sub> RESIST ON IMPURITY DIFFUSION AND OXIDATION IN SILICON.** Selective masking effects of a WO<sub>3</sub> electron resist on phosphorus diffusion and oxidation in silicon at 1000°C are described. Though the diffusion coefficient of phosphorus in the WO<sub>3</sub> layer is about twice as large as that in the SiO<sub>2</sub> layer, the WO<sub>3</sub> resist is useful as a masking film for phosphorus diffusion at elevated temperatures around 1000°C. On the other hand, the masking effect of the WO<sub>3</sub> layer on the oxidation of a silicon substrate is insufficient, since the diffusion coefficient of O<sub>2</sub> molecules in the WO<sub>3</sub> layer is about eight times as large as that in the SiO<sub>2</sub> layer. (Author abstract) 7 refs.

**095350 ANODIC PASSIVATION OF.** As part of a comprehensive electrochemical investigation of silicon etching and anodic passivation in KOH, chronoamperometric experiments were performed on precisely oriented {111} silicon to elucidate the mechanistic course of silicon {111}RTBC passivation. The resulting current vs. time relationships display multiple current maxima that obey two-dimensional nucleation and first-order reaction rate laws. Each current peak has been associated with either the formation of an anodic oxide or the dissolution of an open-circuit oxide film. Data analysis confirms previous results which show that anodic oxide formation on {111} silicon consumes a fixed quantity of charge of approximately  $2.4 \times 10^{-3}$  C/cm<sup>2</sup> for both n- and p-type silicon. (Author abstract). 31 Refs.

#### Purification

**095354 SILICON PURIFICATION BY THE VAN ARKEL-DE BOER TECHNIQUE USING A Cu<sub>3</sub>Si:Si COMPOSITE ALLOY SOURCE.** Production of 99.9999% pure silicon by the Van Arkel-De Boer technique is described. The purification method is based on an HCl chemical vapor transport process using a Cu<sub>3</sub>Si:Si composite alloy as the silicon source. The concentration, origin, and behavior of the major impurities (Al, B, Ba, Ca, Cr, Fe, Mg, Mn, Mo, Ni, P, Ti, V, and Zr) involved in the process were studied by Atomic Absorption-Inductively Coupled Plasma (AA-ICP), Spark Source Mass Spectrometry (SSMS), and X-ray Fluorescence Analysis (XFA). Finally, the purification mechanisms and their relative importance in the overall process are discussed for these impurities. (Author abstract) 12 refs.

**095356 PURITY CONSIDERATIONS FOR AMORPHOUS SILICON THIN FILMS.** Contamination control is essential to prepare high quality amorphous silicon thin films for device applications such as solar cells and thin film transistors. Topics included in this paper are vacuum system preparation and reduction of residual gases, silane gas purity considerations, dopant contamination control, and particulate contamination control. The first topic, vacuum system preparation, considers the design and construction of vacuum systems and common vacuum practice used to minimize contamination in deposited films of amorphous silicon. The use of residual gas analyses and the measurement of desorption rates to reduce system contamination is discussed in detail. Next, gas chromatography/mass spectrometer analyses of silane and other feedstock gases from major producers are presented. Two methods, gas flushing and gas flow isolation, illustrate the techniques used to prevent dopant contamination. Finally, because most amorphous silicon deposition systems produce particulates which reduce the yields of fabricated devices, methods are discussed which minimize unwanted particulate production. (Author abstract) 11 refs.

**Radiation Damage** See Also TRANSISTORS, BIPO-LAR—Radiation Damage.

**095357 INFLUENCE OF IRRADIATION TEMPERATURE ON RADIATION DEFECT ACCUMULATION IN SILICON.** The processes of radiation defect formation in n-type silicon are studied at various irradiation temperatures ( $T_{irr}=20$  to  $400^\circ\text{C}$ ) during 640 MeV proton or 10 MeV electron bombardment. The results are obtained from the analysis of the temperature dependences of charge carrier concentration in crystals irradiated at various temperatures and investigating samples (which are not irradiated but subjected to similar thermal treatment). It is established that production efficiencies for main radiation defects (A-, E-centers, divacancies, complexes of carbon-oxygen-divacancy) are complicated functions of  $T_{irr}$ , however the form of these functions appears to be different for the two types of irradiation used. The results obtained are interpreted. (Edited author abstract). 18 Refs.

**095358 NEUTRON DAMAGE EQUIVALENCE FOR SILICON, SILICON DIOXIDE, AND GALLIUM ARSENIDE.** Displacement-energy and ionization-energy transfers to Si, SiO<sub>2</sub>, and GaAs as functions of incident neutron energy were calculated using cross-section data and fine group structure in the NJOY code system. Neutron spectra determinations for several reactor neutron environments were made using activation cross sections and a novel technique with the SAND II code. Measurements of carrier-removal rates in GaAs and

of Si transistor gain degradation were made in representative neutron environments. Experimental results are compared to damage ratios predicted with the spectra and NJOY displacement functions. For fission-like spectra, calculated Si damage ratios are in good agreement with those determined with ASTM E722-85 and with measured transistor damage ratios. Significant differences are found between Si NJOY and ASTM E722-85 for 14-MeV-to-reactor neutron damage ratios; NJOY gives better agreement with experimental data reported in the literature. In GaAs, 14-MeV-to-reactor experimental damage ratios are smaller than predicted by calculated displacement ratios. This suggests that a more complex model of damage for majority carrier removal in GaAs is required. 26 refs.

**095359 INVESTIGATION OF SIH IR ABSORPTION PEAKS IN NEUTRON-IRRADIATED FZ-SI CRYSTAL CONTAINING HYDROGEN AT LOW TEMPERATURE.** The Si-H IR absorption peaks in the neutron-irradiated FZ-Si crystal containing hydrogen are investigated using the low-temperature (10 K) Fourier transform infrared absorption spectroscopy. More hydrogen-related IR peaks than those in the case of room-temperature spectroscopy including the fine structure of the 1980  $\text{cm}^{-1}$  peak and the correlation between the 1839  $\text{cm}^{-1}$  and 817  $\text{cm}^{-1}$  peaks have been found. The annealing behavior of above-mentioned low-temperature peaks is shown more definitely than that at room temperature. The configurations of these peaks are discussed. (Author abstract) In Chinese. 9 refs.

**095360 EFFECT OF IRRADIATION WITH ELECTRONS ON THE ETCHING OF SILICON SINGLE CRYSTALS.** In silicon single crystals irradiated with fast electrons, a microrelief reflecting the shape of the crystallization front, not visible in unirradiated crystals, was revealed by selective etching. In addition, in dislocation-free crystals after irradiation a change in the shape of the etching pits caused by the presence of A-defects in the investigated material was observed. The appearance of a microrelief attests to a nonuniform distribution of radiation defects, while the change in the shape of the etching pits is apparently the result of an interaction between primary radiation defects and growth microdefects. In Russian. 13 refs.

**095361 TEMPERATURE RISE OF SMALL SILICON PARTICLES DURING LASER IRRADIATION.** The temperature of small silicon particles during laser irradiation was estimated from the Raman spectra of the particles. The relationship between the peak frequency shift and the linewidth of the experimental data was compared with a theoretical calculation made by Balkanski et al. This comparison has enabled us to determine the temperature of the silicon particles during laser irradiation. (Author abstract) 6 refs.

**095363 DIVACANCIES PRODUCTION IN IRRADIATED N-TYPE SILICON.** Measurements of loss factor and capacitance made on single crystals of P-doped n-type silicon are reported. Samples are irradiated with  $(1.00 \pm 0.20)$  MeV electrons at temperatures  $< 12$  K. The production of divacancies in the irradiated samples is monitored using hopping conductivity changes at 4.2 K. Higher divacancy production is observed in Czochralski-grown samples and samples containing appreciable concentrations of group III impurities. This suggests that oxygen and group III impurities trap the self interstitials, mobile under irradiation conditions, thus inhibiting divacancy-self-interstitials annihilation. Effects of irradiation on the free carriers conductivity of the samples are also investigated. (Author abstract) 13 refs.

**095364 CEMS ANALYSIS OF  $\text{Ar}^+$  IRRADIATED  $\text{Fe}/\text{SiO}_2$  SYSTEM.** Ion-beam induced mixing effects on metal/insulator systems have been recently studied to shed light on the different physical mechanisms responsible for the atomic transport process at the interface. When a Mossbauer isotope is present as a constituent of the system or as a probe, conversion electron Mossbauer spectroscopy (CEMS) can investigate some microstructural aspects of the mixed layer such as chemical environment, local atomic arrangement, magnetic ordering, etc. The authors report preliminary results on CEMS characterization of the  $\text{Fe}/\text{SiO}_2$  interface after  $\text{Ar}^+$  irradiation. It is possible to evaluate the iron areal density from each CEM spectral component by combining the Rutherford backscattering spectrometry absolute value of the areal density with the relative amount of the Mossbauer component. 12 refs.

**095365 KINETICS OF THE FORMATION OF THE THERMAL DONORS IN SILICON. EFFECT OF VARIOUS PARAMETERS.** Annealing at 450 °C of oxygen rich silicon generates nine hydrogenic double donors (thermal donors whose ionization energies are about 60 meV for neutral states and 145 meV for ionized states. New kinetics of thermal donor formation are reported and the effect of various parameters is discussed. The essential role of the initial characteristics of the material and its thermal history are pointed out. Experiments of electron irradiation performed at room temperature before the generation of thermal donors rule out the contribution of intrinsic defects like single- and multivacancies to the clustering process leading to thermal donor formation. (Author abstract) 31 Refs.

**095366 DYNAMICS OF OPTICAL PARAMETERS OF SILICON AND GERMANIUM SINGLE CRYSTALS DURING TWO-PULSED NANOSECOND LASER IRRADIATION.** The behaviour of the reflectivity and ellipsometric parameters  $\psi$  and  $\Delta$  of silicon and germanium single crystals was investigated experimentally during two-pulsed laser irradiation. A comparison of the experimental data with the results obtained in solving Stefan's nonlinear problem and with the temperature dependences of the measured optical quantities shows that the maximum temperature of the melt surface of a semiconductor is lower than the value predicted by the simple model of laser annealing. The absence of surface

overheat may be attributed to hydrodynamic phenomena which can develop in liquid phase in the process of the melting front movement. (Edited author abstract) 29 Refs.

Gusakov, G.M. (Moscow Inst of Electronic Technology, Moscow, USSR); Komarnitskii, A.A.; Em, A.S. *Phys Status Solidi A* v 107 n 1 May 1988 p 261-271.

**095367 HIGH-RESOLUTION ELECTRON MICROSCOPY OF SI CONES FORMED ON  $\text{Ar}^+$ -BOMBARDED SI WAFERS.** Conical Si projections generated on Si wafers bombarded with obliquely incident  $\text{Ar}^+$  ions were studied by high-resolution transmission electron microscopy. The cones were composed of an [111]-oriented bulk phase covered with a disordered thin layer, but the bulk phase was not perfectly ordered, containing an amorphous domain underneath the outermost area. Such a multi-phase structure is inexplicable in terms of ion erosion, suggesting interplay of the redeposition of sputtered Si atoms on the bombarded area with the ion-erosion process so as to promote cone evolution. The cones were also characterized by the development of web-like platelets at their acute angles, an indication of a crystal growth process involved in the surface phenomenon observed. (Author abstract) 26 Refs.

**095368 RADIATION EFFECTS IN  $\text{SiO}_2/\text{Si}$  STRUCTURES.** In this paper, differences of the radiation effects by X-ray and  $\gamma$ -ray were examined. The device characteristics of an Si MOS transistor are strongly dependent on the Si surface, that is, the  $\text{SiO}_2$  film and the  $\text{SiO}_2/\text{Si}$  bipolar transistor are dependent on both the Si crystalline properties and the Si surface. Therefore, bipolar transistors were used in this study. As a result, there was no noticeable difference between radiation effects by X-ray and  $\gamma$ -ray and the effects were due mainly to the property change at the Si/ $\text{SiO}_2$  interface. The radiation effects in the  $\text{SiO}_2$  Si structures were studied by the capacitance-voltage (C-V) characteristics of MOS diodes. The dependence of the radiation effects on the MOS diode fabrication processes was also examined. 23 Refs.

**095369 RADIATION AND PROCESSING INDUCED EFFECTS IN SIMOX: A SPECTROSCOPIC STUDY.** The SIMOX formation process has been studied with electron spin resonance (ESR), IR spectroscopy, and photoluminescence. Samples were implanted with doses from  $0.5 \times 10^{18}/\text{cm}^2$  to  $2.6 \times 10^{18}/\text{cm}^2$  and annealed at 600°C to 1275°C. The  $\text{P}_b$  and radiation induced  $\text{E}'$  centers were measured with ESR. By measuring the  $\text{P}_b$  concentration, it is shown that oxide precipitates are concentrated in the superficial silicon layer and that they coalesce into the buried oxide with annealing. The stoichiometry of the buried layer is examined with IR. At 600°C the stoichiometry,  $\text{SiO}_x$ , ranges from  $x = 1.4$  to  $x = 1.6$  depending upon the implant dose. The stoichiometry approaches that of thermal oxide,  $\text{SiO}_2$ , at 1150°C and above. Photoluminescence from the D lines, caused by dislocations, is observed and the structural implications are discussed. 27 refs.

**095370 RECOMBINATION CENTERS AND ELECTRICAL CHARACTERISTICS IN SILICON POWER P-I-N DIODES IRRADIATED WITH HIGH ENERGY ELECTRONS.** Recombination centers introduced by irradiation with 12 MeV electrons in large area silicon diodes with p-i-n structure are studied by the Deep

Level Transient Spectroscopy technique (DLTS). The effects of these levels on the electrical characteristics of the devices are related to their position  $E_t$  in the silicon forbidden gap, their concentration and their electron capture cross section. Changes of defect configuration during an annealing process at 360°C have been observed and a detailed analysis of the DLTS spectra has shown a complex defect pattern. The complex structure of the centers has been studied and demonstrated with the aid of proper modelling implemented on a set of numerical simulation tools. (Edited author abstract) 24 refs.

**095371 LIGHT-INDUCED METASTABLE STATE IN DOPING-MODULATED AMORPHOUS SILICON SUPERLATTICES.** Photo-induced decrease in conductance after long light exposure has been observed for hydrogenated amorphous silicon (a-Si:H) npn... doping-modulated superlattices showing large persistent photoconductivity (PPC). The initial increase in PPC is taken over by the decrease even to the negative PPC after long illumination. This light-induced, metastable conductance can be recovered completely by 160°C annealing, which is independent of exposure time. In particular, the metastable defects created in the p-layers are found to be annealed out at 100°C. These results strongly suggest the creation and annealing of dangling bonds by light-soaking and annealing in doping-modulated superlattices. (Edited author abstract) 14 refs.

## Recrystallization

**095372 CW ARGON-LASER INDUCED ZONE-MELTING RECRYSTALLIZATION OF THIN SILICON ON OXIDE.** This paper describes a CW argon laser-induced zone-melting recrystallization technique. Large areas of single-crystalline silicon films on SiO<sub>2</sub> were obtained. The main features of this technique are the combination of seeding structures, a specially-shaped laser-beam spot and a locally-altered capping layer. Single-crystal silicon islands of 50  $\mu\text{m} \times 165 \mu\text{m}$  with the same <100> orientation as the silicon substrate have been successfully obtained. p-Channel depletion MOSFETs ( $w/L = 40 \mu\text{m}/10 \mu\text{m}$ ) were fabricated in the recrystallized film. The  $I_D-V_D$  characteristics of the devices were excellent. The surface hole mobility was 170  $\text{cm}^2/\text{V}\cdot\text{s}$ . 15 refs.

## Reviews

**095373 SILICON WAFERS FOR THE 1990'S.** This review covers the status, trends and characteristics of silicon wafers which will be needed for future fabrication of microelectronic devices. The most pervasive silicon use will be for standard CMOS and possibly BiCMOS, for ASIC with mature design rule technologies. Larger diameter wafers, e.g. 6-8 inches with pp+ and p- substrates will become more common. A number of topics and issues important in today's research and development are discussed. (Author abstract) 39 refs.

**095374 ANOMALOUS FEATURE ON THE DLTS SPECTRUM OF SILICON.** The behavior of a very curious feature arising on the DLTS spectrum of LN<sub>2</sub> electron-irradiated pulled silicon is studied. It is shown that this behavior is not consistent with a normal DLTS peak caused by the trapping and emission of carrier from a deep level. However, it is almost certain that this feature is a result of the low-temperature irradiation of the pulled silicon. A model is proposed based on the oxygen trapping at abnormal sites in the silicon lattice. (Author abstract) 11 refs.

**095375 CHARACTERIZATION OF SMALL DIFFERENCES IN SURFACE POLISHING QUALITY OF SILICON WAFERS BY SPECTROSCOPIC ELLIPSOMETRY.** The surface trace imperfection of silicon wafers resulting from different polishing technologies has been quantitatively characterized by use of spectroscopic ellipsometry. The dielectric function  $\epsilon = \epsilon' + i\epsilon''$  for the residual damaged thin layer at the surface was calculated from the ellipsometric parameters  $\Psi$  and  $\Delta$  on the basis of a four-phase model. Results show that (i) A diagnosis for very small differences between various conventionally adopted polishing processes can be realized in the  $E_1$  spectroscopic structure of the silicon interband transition region, rejecting the necessity of  $E_2$ -structure which emerges from a shorter UV range. (ii) It seems that for silicon, a higher sensitivity for the surface imperfection may be obtained with the real part  $\epsilon'$  of the dielectric function than its imaginary  $\epsilon''$  the wavelength range of  $E_1$ . **095377 FAR-INFRARED ABSORPTION AND NEAR-INFRARED EXCITATION SPECTROSCOPY OF ISOELECTRONIC BOUND EXCITONS IN Si-Be + C.** Intense photoluminescence from the axial isoelectronic center formed by a pair of Be atoms occupying a Si vacancy is often accompanied by a weaker set of lines lying at higher energy. A correlation between the intensity of these lines and the concentration of C in the sample led to the suggestion that the new center is a Be-Be center perturbed by a nearest-neighbor C. Our measurements reveal strong similarities between the excited states of both systems, supporting this model. (Author abstract) 9 refs.

**095378 SIMS ANALYSIS, UNDER CAESIUM BOMBARDMENT, OF Si IN GaAs/(Al, Ga) AS SUPERLATTICES: DETECTION LIMIT AND DEPTH RESOLUTION.** The secondary ion mass spectrometry technique has been revealed as a very powerful method for such a determination. But, in this particular case, some difficulties are encountered at low doping levels because of the presence of ions interfering with the main silicon isotope at mass 28. This paper deals with the search

for satisfactory experimental conditions for such a silicon analysis under cesium primary ion bombardment, the main requirements being the detection limit and the depth resolution. It will be shown that AJH molecular ions are the interfering species and two approaches have been explored to avoid this interference: use of high mass resolving power facilities of a double focusing mass spectrometer, or experimentation at low vacuum conditions. A compromise is inevitable between maximum sensitivity in the  $1-2 \times 10^{15} \text{ cm}^{-3}$  range by detecting negative secondary ions and good depth resolution, equal to about 40 angstrom, by using positive secondary ion collection. The ultimate performances of the technique are limited by the silicon surface segregation process. (Edited author abstract). 19 Refs.

**095379 SPECTROSCOPIC STUDIES OF DOUBLE DONORS IN SILICON.** We briefly review optical excitation spectroscopy of isolated double donors in silicon. We discuss how energies of optically forbidden states may be determined, either i) from phonon-assisted Fano resonances above the ionization limit; or ii) by shifting forbidden states into resonance with allowed transitions through the application of uniaxial stress. For neutral donors with two bound electrons, the importance of many-body effects has recently been demonstrated by a first study of spin-triplet states under uniaxial stress. We discuss the implications for the electronic structure of double donors and the question whether these systems may be viewed as solid-state analogues of helium. Finally, for singly ionized double donors, we find that the behavior of the deepest excited states under uniaxial stress cannot be accounted for within effective-mass theory and the deformation-potential approximation. (Author abstract) 48 refs.

## Spectrum Analysis

**095385 ZINC-RELATED ISOELECTRONIC BOUND EXCITON IN SILICON.** Photoluminescence (PL), photoluminescence excitation (PLE), and photoluminescence lifetime measurements are reported for a newly-discovered optical centre in a silicon sample diffused with iron and zinc. The PL spectrum consists of two thermalizing no-phonon lines, each with sharp low energy local mode phonon replicas in addition to a broad multiphonon sideband. The no-phonon lines, at  $1059.93 \pm 0.05$  and  $1075.12 \pm 0.05$  meV, are attributed, respectively, to transitions from the spin triplet and singlet states of an isoelectronic bound exciton (IBE). Other states of the IBE are observed at  $1108.4 \pm 0.5$ ,  $1110.0 \pm 0.5$  and  $1133.2 \pm 0.5$  meV in the PLE spectrum, which also shows sharp local mode phonon replicas. The energy level structure is consistent with IBE states formed by a hole and an electron subject to a large ground state valley-orbit splitting, and bound at the centre by approximately 82 meV. (Author abstract) 21 refs.

## Structure

**095387 CONSTRUCTION OF BOND-CENTERED WANNIER FUNCTIONS FOR SILICON VALENCE BANDS.** Bond-centered Wannier functions are constructed for the valence bands of silicon by a direct superposition of the Bloch functions whose phases are chosen on physical grounds. The Bloch functions are calculated using the linear muffin-tin orbitals method within the local density approximation. The resulting four Wannier functions per unit cell are equivalent to one another. Each is localized on a bond-center, has the  $\Gamma_1$  symmetry of the  $D_{3d}$  group, and falls off exponentially. (Author abstract) 29 refs.

**095388 EFFECT OF HYDROGEN DILUTION ON STRUCTURE OF a-Si:H PREPARED BY SUBSTRATE IMPEDANCE TUNING TECHNIQUE.** The effect of hydrogen dilution of a source gas,  $\text{SiH}_4$ , on structural inhomogeneity has been studied for hydrogenated amorphous silicon films prepared under the mode involving a high deposition rate by the substrate impedance tuning technique. As the silane fraction decreases from 100% to 1% with hydrogen dilution, the SiH bonding configuration gradually changes into the dihydride ( $\text{SiH}_2$ ) group; finally, the films become microcrystalline. On the other hand, the state density in the mid gap and the spin density, related to the structural disorder, have minima at silane fractions of 100% and 10%. These results seem to be consistent with a two-phase model suggested for high rate films, with an emphasis on a different medium range disorder between the films prepared at high and low deposition rates. (Author abstract) 15 refs.

**095389 CALCULATED BAND GAPS AND EXCITED STATES IN SEMICONDUCTORS.** A method of treating the screening by valence electrons in a semiconductor which takes account of the lower and more uniform charge density in the regions between atoms is applied to silicon and cadmium sulphide. Improved values of the band gap are obtained and these results along with the densities of states and energy bands in the region of the gap are discussed. (Author abstract). 10 refs.

Ali Dahr, A.-I. (Univ of Lancaster, Lancaster, Engl); Lee, P.M. *Phys Scr* v 38 n 3 Sep 1988 p 441-443.

**095390 MODELING THE STRUCTURE OF AMORPHOUS SI BY SIMULATED ANNEALING.** We have developed a computer algorithm to generate models for tetrahedrally coordinated random networks, the prototypical example being a-Si. The method is easily extended to many other systems, a-SiO<sub>2</sub> being an example. The starting point is a supercell in the diamond cubic structure. Periodic boundary conditions are imposed so as to eliminate surface effects. The algorithm uses an elementary topological rearrangement that is randomly and progressively introduced into the diamond cubic structure until a random network has been generated. This is followed by an 'annealing' process that allows topological relaxation of the structure, leading to a structural model in agreement with experiment. We also describe a solution

to the traveling salesman problem that is identical in all important respects to modeling the structure of a-Si. The simple topology and the two-dimensional character of the traveling salesman problem make it possible to give an explicit example of a metastable state. (Edited author abstract) 11 refs.

**095391 EVALUATION OF DISLOCATION GENERATION IN U-GROOVE ISOLATION.** The density of dislocations generated on a silicon substrate in a groove structure is measured. In addition, the effects of the topographical structure and isolation groove oxidation conditions are investigated. Results show that the generation of dislocations greatly depends on the shape of the groove and the oxidation temperature. These results can be interpreted as being due to both the effect so the stress concentration during selective oxidation in the groove and the viscous flow of a  $\text{SiO}_2$  film. Also studied are suitable structure and process conditions for U-groove isolation by making use of the experimental results and stress analysis. (Edited author abstract) 17 refs.

**095392 MOLECULAR BEAM HOMOEPITAXY ON Si(100) SUBSTRATES.** Molecular beam homoepitaxy of silicon on Si (100) and Si (111) substrates has been done with a UHV electron beam evaporation system. It is found that, after the substrate is chemically cleaned, a flat and ordered surface can be obtained by heating the substrate at UHV at a relatively low temperature (800-814°C). The epitaxial films of Si on Si (100) and Si (111) are deposited at the substrate temperature of 520°C and 714°C, respectively. The crystal structure and electrical properties of the epitaxial films are fairly satisfactory. (Edited author abstract). 2 Refs. In Chinese.

## Surface Properties

**095393 THEORY OF TWO-CENTER BOND FOR ON-TOP SITE ADSORPTION ON SILICON (111) SURFACE.** The theory of two-center bond has been applied to the on-top site adsorption of atomic H, O, F and Cl on Si (111) surface. The theory gives a systematic analysis for their bond length, charge population, force constant and, by a simple molecular model, local vibrational frequency. The adatom-induced valence band PES is discussed from a self-consistent calculation of bond orbitals in a previous paper. The results are comparable to ab initio and CNDO calculations for the same problem. For O and Cl adsorptions, the theory leads to agreement with experiments. (Author abstract). 10 Refs. In Chinese.

**095394 ANALYSIS OF THE ATOMIC STRUCTURE OF THE Si(111)  $\sqrt{3}\times\sqrt{3}$ -Bi SURFACE BY X-RAY PHOTOELECTRON DIFFRACTION.** It is found by X-ray photoelectron spectroscopy and LEED that the saturation coverage of Bi is one monolayer for the Si(111) $\sqrt{3}\times\sqrt{3}$ -Bi surface. Azimuthal dependence of Bi 4d photoelectron diffraction has been measured for the Si(111) $\sqrt{3}\times\sqrt{3}$ -Bi surface and analyzed kinematically. The results of the analysis have confirmed the presence of Bi-triplets with sides of 3.1 Å as proposed by X-ray diffraction. It is further found that the Bi-triplets form an overlayer on the substrate. (Author abstract) 14 refs.

**095395 SILICON [113] SURFACE AS A TEST FOR SURFACE-ENERGY CALCULATIONS.** Surface-energy calculations have, in the past, been undertaken for a wide range of silicon surfaces with a degree of success that remains unclear. They suggest, for example, that the {113} face has a particularly high energy, but this is in direct conflict with the results of thermal etching. Simulated profile images of the theoretically derived silicon {113} surface and of a reconstruction based upon 'rebonding at steps' are here compared with recent observations. It is concluded that the former model may be discounted, while the latter, hitherto dismissed on theoretical energy grounds, gives good qualitative agreement with experiment. The practical implications of this are discussed briefly. (Edited author abstract) 13 refs.

**095396 ROLE OF STRUCTURAL DEFECTS AND ADMIXTURES IN RECONSTRUCTING A (100) SILICON SURFACE.** The (100) facet of silicon is investigated using methods of diffraction of slow electrons and electron Auger spectroscopy. (2 by 1), p(2 by 2) and c(4 by 4) superstructures are noted as the surface admixtures are removed from the sample. The c(4 by 4) superstructure is shifted into a (4 by 1) superstructure with subsequent electron effects ( $T=450^\circ\text{C}$ ,  $E=3\text{ keV}$ , and  $D=5\cdot 10^{19}\text{ electrons/cm}^2$ ). A model of the mutual transition of the cited elementary cells with each other is constructed using a quantum-chemical approximation of valent bonds. (Author abstract) 17 refs.

**095397 ON THE INTERACTION OF HALOGEN ATOMS WITH (111) AND (100) SURFACES OF SILICON.** The chemisorption of F, Cl, Br, and I atoms on the (111) and (100) surfaces of silicon has been studied by the MNDO method and using clusters of Si atoms to simulate the substrate. In the case of the adducts  $\text{F-Si}_4\text{H}_9$  and  $\text{Cl-Si}_4\text{H}_9$  the MNDO results are in close agreement with previous ab-initio ones concerning both the equilibrium distance and the chemisorption energies. For all the cases considered, the binding energy decreases in the order  $\text{F} > \text{Cl} > \text{Br} > \text{I}$ . The most stable adduct is always obtained upon chemisorption at the bridge position on the (100) surface. Chemisorption at on-top positions leads to slightly less stable adducts and is nearly isoenergetic on (100) and (111) surfaces. All the results are essentially insensitive to the dimensions of the clusters used to simulate the substrate. (Author abstract) 21 refs.

**095398 ELECTRON-BEAM-INDUCED CURRENT OBSERVATION OF MISFIT DISLOCATIONS AT  $\text{Si}_{1-x}\text{Ge}_x/\text{Si}$  INTERFACES.** The electron-beam-induced current (EBIC) method has been applied to observing the misfit dislocations at  $\text{Si}_{1-x}\text{Ge}_x/\text{Si}$  interfaces in order to determine directly the dependence of critical layer thickness  $h_c$  on mole fraction  $x$ . The EBIC images show square-grid patterns that agree with a

chemical etched pattern. The typical dislocation image width obtained by EBIC is about 0.5  $\mu\text{m}$ , which approximately agrees with the resolution introduced from the lateral-dose function. It has been found that the dependence of  $h_c$  on  $x$  judged from whether or not the misfit dislocations generate cannot be explained by the theory presented by R. People and J.C. Bean. (Author abstract) 8 refs.

**095399 HIGH RESOLUTION INVESTIGATION OF THE ROD-SHAPED SCATTERING FROM A (111) Si SURFACE BY A SYNCHROTRON RADIATION SOURCE.** By using a high resolution X-ray spectrometer in conjunction with a synchrotron radiation source, the rod-shaped scattering due to crystal truncation (RSCT), which is elongated along the normal of a crystal surface through a Bragg point, was investigated for two (111) silicon wafers of which the surfaces were differently processed. It is shown that the characterization of a crystal surface, on the basis of surface roughness on an atomic scale and the misorientation of mosaic blocks, is really possible by the precise measurement of the RSCT. (Author abstract) 7 refs.

**095400 IMPEDANCE STUDY OF THE SILICON-SOLUTION INTERFACE UNDER ILLUMINATION.** Surface states at the semiconductor-electrolyte interface under illumination have been determined. The Faradaic reaction involved at the interface is the hydrogen evolution. An equivalent circuit is proposed which is chosen as giving the best fit to the impedance data among six possible arrangements consistent with present models of the interface. Surface states act as recombination centers decreasing the Faradaic efficiency for the hydrogen evolution reaction. Surface state density at a given bias potential has been calculated to be  $\approx 10^{12}\text{ cm}^{-2}$ . Adsorbed ions induce surface states. Helmholtz double layer resistance is larger than the space charge resistance in the Tafel region; hence, the rate determining step for hydrogen evolution on Si lies in the double layer region. (Author abstract) 51 refs.

**095401 DISLOCATION MEDIATED PSEUDO-MELTING AT SILICON-METAL INTERFACES.** The silicide formation between silicon and transition as well as noble metals occurs at 0.3-0.4 of the melting temperature of silicon. It is proposed that the chemical reaction is preceded by an interfacial melting process due to defect generation (dislocation or disclination) via the Koestertiz-Thouless mechanism. This is possible at temperatures lower than the melting temperature due to overall softening of the shear vibration mode of the surface silicon layers and may lead to the low temperature chemical reaction observed. The softening mechanism of atoms on the (111) surface of silicon due to the metal overlayer is suspected to be both elastic and electronic in origin, and leads to the breaking of the strong covalent silicon bonds at low temperatures. 13 refs.

**095402 USING PULSED HOLOGRAPHIC INTERFEROMETRY FOR EXAMINING THE DYNAMICS OF DEFORMATION OF THE SILICON SURFACE IN LASER IRRADIATION.** The authors developed a method of using pulsed holographic interferometry for measuring mechanical displacements of the surface of

solids under the effect of pulses of laser radiation. The profiles of displacement of the surface of the irradiated and adjacent zones in relation to the energy and passage time of the laser radiation pulse are constructed. It is shown that the high-speed heating and cooling of the material plays the controlling role in formation of the mechanical displacements of the surface of silicon. (Author abstract) 7 refs.

**095404 OSCILLATIONS OF THE SPIN AND VALLEY SPLITTINGS IN THE 2D-ELECTRON ENERGY SPECTRUM ON THE (100) SURFACE OF SILICON.** A spectroscopic method based on measurements of the luminescence spectra related to the radiative recombination of two-dimensional electrons with photo-excited nonequilibrium holes was applied for direct determination of the intervalley and spin splittings in the energy spectrum of two-dimensional electrons in a perpendicular magnetic field. Strong oscillatory dependences of these splittings on the filling factor have been observed. It is shown that the splittings increase by almost an order of magnitude due to the electron-electron interaction. (Edited author abstract) 18 refs.

**095407 ABOUT THE SENSITIVITY OF IN SITU DIFFRACTION MEASUREMENTS WITH X-RADIATION OF A LASER-PRODUCED PLASMA.** Investigations were made of the angular resolution suitable for the temperature determination of a heated surface layer on (111)-oriented silicon by means of X-ray diffraction experiments with characteristic line emission of a laser-produced silicon-plasma. To model the thermally expanded layer a silicon crystal was implanted with  $1 \times 10^{15}$ ,  $0.2 \times 10^{15}$ , and  $2.1 \times 10^{15}$  boron-ions/cm<sup>2</sup> at 60, 100, and 150 keV, respectively. The maximum deformation obtained by the implantation process amounts to approx.  $3 \times 10^{-4}$  in an approx. 0.5  $\mu$ m thick surface layer. This deformation corresponding with a temperature increase of about 100 K may be detected by means of in situ X-ray diffraction methods. (Author abstract) 18 refs.

**095408 COMPUTER SIMULATION OF LEDGE FORMATION AND LEDGE INTERACTION FOR THE SILICON (111) FREE SURFACE.** Both strip and triangular clusters, composed of  $\langle 211 \rangle$  ledges, have been simulated on the Si (111) surface. The long range ledge-ledge interaction and the surface stress tensor distribution have been evaluated for these two pill-box geometries using a semi-empirical potential energy function that incorporates both two-body and three-body contributions. The consequences of the ledge-ledge interaction on two-dimensional nucleation for Si(111) has been evaluated as a function of Si adatom supersaturation and shows to differ significantly from conventional theory where such interaction is neglected. (Author abstract) 8 refs.

**095409 PHASE TRANSFORMATIONS AT A NICKEL-SILICON INTERFACE UNDER TRANSCIENT ANNEALING.** We use intense incoherent light pulses of approximately 60  $\mu$ s duration to induce reactions at a Ni-Si interface. Changes in morphology, composition, and electrical characteristics of the interfaces are studied. The diagnostics include scanning electron microscopy, Auger spectroscopy, X-ray analysis, and diffusion analysis. After annealing for a total of approximately 1 ms, the Si surface is found to support an intermixed and disordered Ni-Si layer consisting of mixed islands and flat structures. On further irradiation, after a certain threshold Ni density is reached in the Si, silicide growth takes place at the interface through an amorphous-to-crystalline transformation of this intermixed layer. The first phase to nucleate is mononickel silicide with a (200) orientation. This is attributed to kinetic effects, which optimize the heat of formation in the presence of excess Si. (Author abstract) 18 refs.

**095410 SCANNING TUNNELING SPECTROSCOPY ON SI.** An overview is given of various methods for applying tunneling microscopy to obtain information on the electronic structure of surfaces. Results are presented for clean Si(111) $\times 7$  and for a Si(111) $\times 7$  surface on which 1/3 monolayer was deposited. The interrelation between constant current topographies and current im-

ages is discussed. It is shown that the current characteristics obtained at a fixed sample-tip distance contain both influences of the local density of states and the transmission probability of the tunneling electrons. Information on the local density of states is not only of fundamental importance but is needed for an accurate interpretation of the constant current topographies and may be used to study the electronic effects upon metal atom adsorption. (Author abstract) 25 refs.

## Synthesis

**095411 SPECIAL FEATURES OF THE PROCESS OF HYDROGEN REDUCTION OF TRICHLOROSILANE IN THE PRESENCE OF WATER VAPOR.** A thermodynamic analysis is made of the process of hydrogen reduction of trichlorosilane in the presence of a residual quantity of water vapor. The equilibrium yield of silicon and silicon dioxide is determined as a function of temperature and trichlorosilane and moisture content in the Si-H-Cl-O system. It is established that the presence of moisture in the hydrogen does not lead to a decrease in the equilibrium yield of silicon. The optimally admissible moisture content, which does not lead to impairment of the structure of the polycrystalline silicon films being grown, is determined. (Translated author abstract) In Russian. 5 refs.

Bogomaz, A.V.; Galkin, P.N.; Levinzon, D.I.; Pravdina, O.V.; Tokarev, V.P. *Tsvet Met* n 1 Jan 1988 p 56-58.

**095412 SILICON FROM MICROWAVE PLASMAS: OPTICAL PROPERTIES AND THEIR RELATION TO STRUCTURE.** Amorphous and microcrystalline silicon films have been fabricated by microwave plasmas in a silane-hydrogen gas mixture under electron cyclotron resonance conditions. Optical properties of these films have been measured for photon energies in the range from 2.0 to 3.5 eV. The results show that the optical gap decreases from 1.70 to 1.40 eV as the structure changes from an amorphous network into a microcrystalline-amorphous mixture. The amorphous to microcrystalline transition is clearly indicated by the spectra of the refractive index  $n$ , and the imaginary part of the dielectric constant  $\epsilon_2$ . The measurements of the  $n$  and  $\epsilon_2$  spectra provide an alternative technique to x-ray diffraction in the investigation of microcrystalline structure, and would be particularly useful for thin films. (Edited author abstract) 31 refs.

## Testing

**095413 NEW METHOD OF DETECTING PINHOLES EXISTING IN a-Si:H FILMS.** Pinholes are often inevitably formed in hydrogenated amorphous silicon (a-Si) film by a plasma CVD method, and they sometimes spoil the performance of the a-Si solar cells. For the a-Si films prepared on stainless steel, the stainless steel substrates were found to corrode at the points of contact with the pinholes of a-Si films by the electrochemical treatment of the a-Si covered plates. The currents flowing during the treatment can be utilized as a measure of the density of pinholes existing in the a-Si films. Many pits were observed on the substrates after the treatment, showing the places where the pinholes existed in a-Si films. By use of this method, the relation between the surface roughness of the stainless steel substrates and the formation of pinholes was clarified. (Author abstract) 9 refs.

Sakai, Yuichi (Osaka Univ, Toyonaka, Jpn); Yae, Shinji; Matsumura, Michio; Nakato, Yoshihiro; Tsubomura, Hiroshi. *Sol Energy Mater* v 17 n 2 Feb-Mar 1988 p 89-94.

**095414 INFLUENCE OF A GATE OXIDE ON THE 1/f NOISE IN SI.** The noise of thin Si samples with a large oxide layer is measured. 1/f noise sources in the bulk and near the semiconductor-oxide interface are observed. The 1/f noise parameter  $\alpha$  of the noise sources in the bulk is lower by a factor of 10 at least than those near the interface. The McWhorter model can explain the gate voltage dependence of the  $\alpha$ -value only at 300 K and its temperature dependence only above 160 K. The gate voltage dependence can also be explained in terms of mobility fluctuations by assuming two parallel layers, a surface layer with a higher  $\alpha$ -value and a lower mobility than the bulk layer. (Author abstract) 8 refs.

## Thermal Properties

**095415 ANHARMONIC EFFECT ON THE THERMAL PROPERTIES OF SI AND GE.** The temperature dependence of specific heat  $C_N$  and thermal expansion coefficient  $\alpha$  for Si and Ge are studied theoretically from first principle by using the lattice dynamical method based on pseudopotentials. The obtained results of  $C_N$  and  $\alpha$  in the harmonic approximation are self-consistent with the observed data of these crystals at low temperatures. At high temperatures, the anharmonic contributions to the specific heat  $C_N^{\text{anh}} = C_N(1 + AT)$  are calculated by using the expression by Trivedi et al. The temperature dependence of the bulk modulus  $B_T$  are quantitatively obtained by considering the lattice vibrational contributions in addition to the static crystal energy. Then, the anharmonic corrections to the thermal expansion coefficient are estimated at high temperatures. The anharmonic coefficient  $A$  for the specific heat and the temperature-dependent decrease of  $B_T$  are quantitatively important at high temperatures for Si and Ge. (Author abstract) 51 refs.

## Thermoelasticity

**095416 THERMOELASTIC RESPONSE OF POLYCRYSTALLINE SI TO AN INTENSE CW LASER BEAM.** We have used analytic methods to obtain closed forms for the thermal strains induced on polycrystalline Si when a cw visible laser beam is focused on its surface. The material is treated as isotropic with appropriately chosen elastic constants. The solution is expressed in terms of the Galerkin vectors for a semi-infinite bulk medium under point dilatation. The results show that considerable strains (corresponding to typical compressive stresses up to 0.5 GPa) are produced even for laser power densities lower than the threshold for melting. Three-dimensional graphical representations are given for the elastic displacements, the strain, and stress components, as a function of appropriate geometrical coordinates. (Author abstract) 27 refs.

## Thick Films

**095417 GENERATION AND CHARACTERIZATION OF THICK SILICON-ON-INSULATOR FILMS.** Seeded recrystallization of thick (up to 25  $\mu$ m) polycrystalline silicon on SiO<sub>2</sub> using a zone melting technique provides films which contain no grain boundaries and exhibit large areas without subgrain boundaries (mm<sup>2</sup>). The results, especially the comparison of the two irradiation systems used (laser and strip heater), indicate the dominating role of the thermal gradient at the crystallization front for the origin and arrangement of defects. The electrical properties measured in CMOS transistors and diodes are comparable to a bulk reference preparation. (Author abstract) 23 refs.

**095418 KINETICS AND MECHANISM OF ELECTROCHEMICAL FORMATION OF POROUS SURFACE LAYERS ON SILICON IN HYDROFLUORIC ACID. INFLUENCE OF ILLUMINATION ON THE KINETICS AND MECHANISM OF ANODIC POROUS-LAYER FORMATION ON n-TYPE SILICON.** The author discusses results obtained when studying the effect of light on the laws of PL growth and of silicon dissolution as the process that is basic to pore formation. Illumination lowers the rate of porous-layer formation under galvanostatic polarization, so that the linear and parabolic kinetics found in the dark is transformed to linear kinetics. Under the effect of light, oxidation of silicon to the divalent state is the predominant reaction; this promotes formation of a more porous structure because of inhibition of the growth of macropores taking place in the dark when silicon dissolves to tetravalent compounds. (Edited author abstract) 13 refs.

**095419 CONSTRAINED FACET CRYSTAL GROWTH OF THIN FILMS ON AMORPHOUS SUBSTRATES.** The crystallization of thin silicon films by scanning with laser-shaped hot zones has been investigated. Large single crystals were obtained on silicon dioxide layer substrates by controlling the shape of the trailing edge of the traveling liquid zone. A model based on thermodynamic driving forces and geometrically limited kinetics within the undercooled region is proposed to describe the mechanism by which the geometry of the hot zone controls the crystallization of thin films on amorphous substrates. (Author abstract) 16 refs.

Aklufi, M. (US Naval Ocean Systems Cent, San Diego, CA, USA); Cadoff, I. *J Electrochem Soc* v 134 n 10 Oct 1987 p 2511-2517.

**095420 EFFECT OF LOW PRESSURE ON THE STRUCTURE OF LPCVD POLYCRYSTALLINE SILICON FILMS.** Structure and crystal growth of undoped silicon films prepared by low pressure chemical vapor deposition (LPCVD) have been investigated by x-ray diffraction, and transmission and scanning electron microscopy. We show that for films deposited in silane partial-pressure range  $2 \times 10^{-4} \leq P \leq 1$  torr and temperature range  $580^\circ\text{C} \leq T \leq 700^\circ\text{C}$ , the pressure is a determining factor for crystallite size, texture, and surface roughness. At a fixed temperature, the crystallite size decreases when the pressure increases. At very low pressures the films have a random orientation. At intermediate pressures the films are characterized by a  $\langle 100 \rangle$  dominant texture and at high pressure, by a strong  $\langle 110 \rangle$  preferred orientation. (Edited author abstract) 22 refs.

Joubert, P. (CNET, Lannion, Fr); Loisel, B.; Chouan, Y.; Haji, L. *J Electrochem Soc* v 134 n 10 Oct 1987 p 2541-2545.

**095421 MECHANISM OF SILICON FILM DEPOSITION IN THE RF PLASMA REDUCTION OF SILICON TETRACHLORIDE.** Plasma-chemical reduction of  $\text{SiCl}_4$  in mixtures with  $\text{H}_2$  and Ar has been studied by optical emission spectroscopy (OES) and laser interferometry techniques. It has been found that the Ar:  $\text{H}_2$  ratio strongly affects the plasma composition as well as the deposition ( $r_D$ ) and etch ( $r_E$ ) rates of Si: H, Cl films and that the electron impact dissociation is the most important channel for the production of  $\text{SiCl}_x$  species, which are the precursors of the film growth. Chemisorption of  $\text{SiCl}_x$  and the reactive surface reaction  $\text{SiCl}_x + \text{H} \rightarrow \text{SiCl}_{(x-1)} + \text{HCl}$  are important steps in the deposition process. The sug-

gested deposition model gives  $r_D \propto [\text{SiCl}_x][\text{H}]$ , in agreement with the experimental data. (Edited author abstract) 29 refs.

**095422 CHARACTERISTICS FOR a-Si:H FILMS PREPARED BY MERCURY-SENSITIZED PHOTO-CHEMICAL VAPOR DEPOSITION.** The density of states in a-Si:H, prepared by mercury-sensitized photo-CVD, was measured by the space-charge-limited current method. The density of Si dangling bonds ( $N_D$ ) was measured by the electron spin resonance method.  $N_D$  and a minimum of the density-of-state near the Fermi level ( $N_{\text{min}}$ ) indicated the same tendency versus substrate temperature, which showed a good correlation between  $N_D$  and  $N_{\text{min}}$ . Both  $N_D$  and  $N_{\text{min}}$  showed a minimum value near substrate temperature of  $200^\circ\text{C}$ . Photosensitivity reached more than  $1 \times 10^6$  for the sample. (Author abstract) 8 refs.

**095423 PROPERTIES OF POLYCRYSTALLINE SILICON GROWN ON INSULATING SUBSTRATES BY ELECTRON BEAM GUN EVAPORATION.** Growth of polycrystalline silicon on insulating substrates such as glass, silicon dioxide and fused quartz was studied using an electron beam gun evaporation technique. Growth characteristics were studied as a function of substrate temperature. The results of scanning electron microscopy, secondary ion mass spectrometry and X-ray diffraction studies on various films are presented. Hall mobility, resistivity and carrier concentration measurements are also presented. Growth of polycrystalline films (as determined by X-ray diffraction studies) on glass substrates at as low a temperature as  $525^\circ\text{C}$  were observed. Below this substrate temperature, films became amorphous. The grain size increased with the increase in the substrate temperature. The highest value of the Hall mobility measured was about  $10 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ . Both n-type and p-type films were obtained. (Author abstract) 15 refs.

**095424 CHARACTERIZATION OF MICROCRYSTALLINITY IN HYDROGENATED SILICON THIN FILMS.** The characterization of microcrystallinity in undoped hydrogenated silicon thin films by means of X-ray diffraction and Raman spectroscopy is discussed in detail. We present experimental results for glow discharge films prepared under a wide range of conditions. Microcrystallinity is characterized in terms of crystalline volume fraction and crystallite size, and it is correlated with deposition rate and substrate temperature. A systematic discrepancy appears between the crystalline fractions determined from X-ray diffraction and Raman scattering and is discussed according to two possible origins: the different Raman cross-sections or the microcrystalline and amorphous phases, and the inhomogeneity of crystallinity as a function of thickness. We show that the accuracy can be improved by using fully recrystallized samples as a reference. (Author abstract) 35 refs.

**095425 SIMPLE METHOD OF SPECTROSCOPIC REFLECTOMETRY FOR THE COMPLETE OPTICAL ANALYSIS OF WEAKLY ABSORBING THIN FILMS: APPLICATION TO SILICON FILMS.** A new reflectometric method enabling the complete optical analysis of weakly absorbing thin films deposited onto absorbing or non-absorbing substrates is described. The interpretation of the envelopes of the extrema present in the spectral dependence of the reflectance characterizing

the film can be performed by means of explicit formulae which allow the spectral dependences of both the optical constants of the film to be determined. The thickness of the film can also be found by an explicit formula. The method is employed for analysing silicon thin films deposited onto glass plates. A comparison of the new method with a similar method using the envelopes in the spectral dependence of the transmittance is performed. (Author abstract) 10 refs.

**095426 CHARACTERIZATION OF MICROCRYSTALLINE SILICON FILMS PREPARED BY THE GLOW DISCHARGE METHOD UNDER DIFFERENT DEPOSITION CONDITIONS.** Microcrystalline silicon thin films have been prepared by rf glow discharge decomposition of silane mixed with hydrogen under different deposition conditions. Rf power, substrate temperature and the dilution of silane with hydrogen have been varied. Structural studies have been based on transmission electron microscopy, X-ray diffraction patterns and Raman spectra. The hydrogen content and its bonding configuration with silicon have been investigated from IR vibrational spectra. Dark conductivity and photoconductivity have been measured and correlated with the structural properties. (Author abstract) 16 refs.

**095427 PREPARATION AND PROPERTIES OF a-SiGe:H FILMS FABRICATED WITH A SUPER CHAMBER (SEPARATED ULTRA-HIGH VACUUM REACTION CHAMBER).** High-quality a-SiGe:H films with low impurity concentrations were studied using a separated ultra-high vacuum reaction chamber system called the super chamber. The ESR spin density and the tail characteristic energy of the a-SiGe films ( $E_{\text{opt}} 1.5 \text{ eV}$ ) were  $6.5 \times 10^{15} \text{ cm}^{-3}$  and 46 meV, respectively. These values were much lower than those for films fabricated in a conventional chamber as well as those for a-Si films. Structural properties, such as the refractive indices and thermal effusion of hydrogen, were also measured. The results suggest that impurity reduction contributed not only to an improvement in the optoelectrical properties, but also the formation of a rigid a-SiGe network. (Author abstract) 7 refs.

**095428 MODELE PRZEWODNICTWA CIENKICH POLIKRYSTALICZNYCH WARSTW KRZEMU.** [Models of Conductivity of Thin Polycrystalline Silicon Films]. The latest models of conductivity of thin polycrystalline silicon films are presented. The development of the carrier's trapping theory is discussed in detail. Much space is dedicated to the new, phenomenal Mandurah et al. model, which is based on the combination of three effects: carrier's trapping, segregation of dopants and carriers detachment from the potential barriers. The model makes it possible to foresee and interpret the dependences of film electric features on thermal processes to which the films are subjected in their production as well as their dependences on dopants. **095431 STUDY OF THE OPTOELECTRONIC AND STRUCTURAL PROPERTIES OF GLOW-DISCHARGE-DEPOSITED FLUORINATED, HYDROGENATED AMORPHOUS SILICON THIN FILMS.** The optoelectronic and structural properties of a-Si:F:H films prepared by the RF glow discharge decomposition of mixtures of silicon tetrafluoride and hydrogen have been studied as a function of the deposition parameters, viz. the hydrogen concentration in the gas mixture, the RF power density and the substrate temperature. It has been found that the deposition parameters can be optimized to prepare photosensitive fluorinated material having a band gap of approximately 1.65 eV. The photoinduced changes in the properties are quite small. Under suitable deposition conditions highly conducting ( $\sigma_D = 10^{-3} \text{ S cm}^{-1}$ ) films can also be produced. (Author abstract) 10 refs.

**095432 QUANTITATIVE MODEL FOR SILICON YIELD STRESS CALCULATIONS AT THIN FILM EDGES.** The results are presented of a theoretical study on the yield stress of dislocation-lean silicon. The obtained yield formula, which expresses the dependence of the external yield force on the intrinsic point defect concentration, is applied to the case of film edge induced dislocation generation in silicon substrates. A generally valid expression for the critical film thickness resulting in homogeneous defect nucleation is derived. The case of an inert anneal of dislocation-lean, oxygen-rich Czochralski silicon is studied more in detail. The theoretical results explain both the qualitative and the quantitative experimental results found in the literature. (Author abstract) 31 refs.

**095433 PHOTOELECTRIC PROPERTIES OF AMORPHOUS SILICON THIN FILMS.** This report describes the photoelectric properties of hydrogenated amorphous silicon films deposited by the plasma chemical vapor deposition method. By the use of a newly established apparatus, it became possible to deposit films with photoconductivity as high as approximately  $3.9 \times 10^{-4} \Omega^{-1} \text{ cm}^{-1}$  in AM1 (100mW) illumination. The energy conversion efficiency was investigated for multi-layer solar cells consisting of both doped (p- and n-types) and undoped (i-type) layers. It was found that the maximum efficiency of 7.8% was attained by the use of a p-i-n structure. The current-voltage characteristics of the fabricated solar cells suggest that the same layer structure is applicable to high-performance photosensors. (Author abstract) 10 refs. In Japanese.

**095434 OXIDISE-ETCH-OXIDISE AND ANNEAL METHOD FOR GROWING HIGH QUALITY ULTRATHIN  $\text{SiO}_2$ .** Silicon wafers if both n- and p-types with orientations (100) and (111) and resistivities in the range of 5 to 6  $\Omega \text{ cm}$  were used. Ultrathin  $\text{SiO}_2$  in the range of 3 to 10 nm grown after subjecting the wafers to dry oxidation in a double walled furnace and HF etching at 1000°C in dry  $\text{O}_2$  and annealed at the same temperature for 30 to 40 min results in lowest fixed oxide charge, fast surface states, and high breakdown voltage which is a linear function of the square root of oxide thickness. This behaviour is attributed to structural and chemical bond modifications introduced by the treatment. 15 Refs.

**095436 KINETICS OF SOLID PHASE CRYSTALLIZATION IN AMORPHOUS SILICON.** Measurements of the kinetics of solid phase crystallization in amorphous silicon thin films are reviewed. Emphasis is placed on characterizing solid phase epitaxy (SPE) and random nucleation and growth (RNG) over a wide temperature range, and on comparing the behavior of intrinsic (undoped) amorphous silicon (a-Si) to that of films containing impurities. Using a combination of laser heating and in situ time-resolved reflectivity measurements, the temperature range over which solid phase crystallization processes can be studied has been greatly extended, allowing temperatures close to the melting point to be explored. Authors review how these techniques are used to characterize the temperature-dependent interplay between solid phase crystallization in a-Si and competitive processes such as impurity segregation, precipitation, and enhanced nucleation. SPE in intrinsic films is shown to be a thermally activated process characterized by a single activation energy, 2.7 eV, over the entire temperature range from 470 to 1350°C. **095437 INFLUENCE OF HYDROGEN SURFACE REACTIONS ON THE GROWTH OF EVAPORATED a-Si:H FILMS.** Thin a-Si:H films are deposited by a direct reaction of evaporated silicon with atomic hydrogen. It is shown that a definite ratio of the number of incoming Si and H atoms is necessary to obtain material without microstructure and with a clear dominance of diluted monohydride bonding configurations. An adequate hydrogen etching process has to take place at the surface of the growing film in order to produce high quality material by the evaporation technique. A steric model is presented which explains the selective etching of  $\text{SiH}_2$  and  $\text{SiH}_3$  bonding sites by atomic hydrogen. (Author abstract) 19 Refs.

**095438 FRENKEL EFFECT IN SIPOS FILMS.** Semi-insulating polycrystalline silicon (SIPOS) has been of great interest in power and device passivation. Such layers inhibit the insurgence of high electric fields at the silicon surface because the equipotential lines are relaxed with respect to the case of an  $\text{SiO}_2$  passivation. The leakage current depends on the electric field and when it

approaches the breakdown value, the behavior is well described by the Frenkel model. In this work this process is investigated in films of different oxygen content and a model is proposed which explains the voltage dependence of the current in the region near breakdown. The question relative to the contribution of this effect to the lowering of the dielectric strength is presented and discussed. 11 Refs.

**095440 PHOTOLUMINESCENCE PROPERTIES IN MICROCRYSTALLINE SILICON FILMS.** The photoluminescence properties of microcrystalline Si ( $\mu\text{-Si}$ ) films are investigated. The dissociation energy of photo-generated electron-hole pairs in band tail states decreases and the non-radiative recombination increases as the crystallization of a-Si:H is enhanced. This is explained as a result of the increase of neutral dangling bonds, which arises from the evolution of hydrogen while the deposition temperature rises. (Author abstract) 5 refs.

## Transport Properties

**095442 METAL-INSULATOR TRANSITION IN COMPENSATED SILICON.** We have measured dc electrical transport properties of compensated silicon, Si:P,B, near the metal-insulator transition at temperatures down to 1.35 K. We have used the variation of the coefficients of the T and  $T^{1/2}$  terms in the temperature dependence of the conductivity to determine  $n_c$ , the critical value of the electron concentration, n. In this temperature range these coefficients appear to be a more sensitive indicator of  $n_c$  than the variation of the zero temperature conductivity with n. The values of  $n_c$  ob-

tained are supported by estimates of  $n_c$  derived from the ratio of values of the Hall coefficient at room temperature and 4.2 K. We find that  $n_c$  increases with increasing compensation, in qualitative agreement with results in previous studies of compensated Ge. However, the increase in  $n_c$  is substantially less than that given by a current theoretical model. (Author abstract) 28 refs.

**095443 EFFECT OF POLYSILICON-SILICON INTERFACE RECOMBINATION VELOCITY ON CURRENT TRANSPORT PROPERTIES OF POLY-EMITTER TRANSISTORS.** Arsenic-implanted polysilicon contact layers show higher current gains than regular arsenic-implanted devices without polysilicon contacting the emitters. The increase in the current gain in polysilicon emitter transistors is due to the reduction in hole (base) current. A practical model has been developed and an analytical expression derived to characterize the hole (base) current transport through an n-type polysilicon emitter in terms of thermionic emission acting in parallel with drift diffusion incorporating the high low junction phenomenon of the poly-silicon-monosilicon interface. 11 Refs.

## Vapor Deposition

**095444 CHANNELING OF 20-100 eV Si ATOMS ABOVE THE Si(111) SURFACE.** The interaction of low-energy silicon atoms with an unreconstructed (111) silicon surface has been studied using molecular dynamics techniques and an accurate description of the covalent Si-Si interaction. For angles of incidence below a critical value, a new phenomenon of 'surface channeling' is observed. In 'surface channeling', the trajectory of the incoming particle is steered by short-range repulsive and long-range attractive interactions with the surface atoms parallel to and roughly 2 Angstrom above, the surface of the substrate. Such surface channeling trajectories offer considerable promise for precision control of beam-induced growth. (Author abstract) 8 refs.

**095445 COMPARATIVE STUDY OF SILICON DEPOSITION FROM  $\text{SiCl}_4$  IN COLD PLASMA USING ARGON,  $\text{H}_2$  OR  $\text{Ar} + \text{H}_2$ .** The deposition of silicon by cold plasmas using  $\text{SiCl}_4$  as the starting gas was studied using argon, hydrogen or a mixture of both as carrier gases. Electron temperatures and densities in these plasmas, as well as plasma species and growth rates, are compared. A good correlation was found between the reaction rates for the decomposition of the reactant and the growth rates of the films in each kind of plasma. The optimal values were measured when a mixture of argon and hydrogen was used. The differences observed between the three plasmas are attributed to the differences in plasma constituents, as detected by the double floating probes system and by mass spectrometry. A schema for the homogeneous (gas phase) and heterogeneous (plasma-surface) interactions in these plasmas is described. (Author abstract) 26 refs.

## X-Ray Analysis

**095446 MEASUREMENT OF THE STATIC DEBYE-WALLER FACTOR OF SILICON CRYSTALS BY THE PENDELLOESUNG FRINGE METHOD.** The static Debye-Waller factor of Czochralski-grown silicon crystals heat-treated at a high temperature has been measured by X-ray section topography. The static

Debye-Waller factor was determined through the variations in the Pendelloesung fringes in a topograph. The measured static Debye-Waller factor was proportional to the square of the scattering vector used, as expected from the theory. From an analysis of the experimental results the average size of the micro-defects formed by the heat treatment could be estimated. (Author abstract) 10 refs.

**095447 X-RAY STANDING WAVES UNDER THE CONDITIONS OF MULTIPLE DIFFRACTION.** Equations are obtained for calculating the angular dependence of the secondary radiation yield (the photoelectron emission or fluorescence radiation) under the conditions of multiple dynamical X-ray diffraction. For a small yield depth  $L_{yi}$  the intensity of secondary radiation is proportional to the intensity of X-rays at the atomic sites of a surface layer of the single crystal. If  $L_{yi} > L_A$ , where  $L_A$  is the X-ray penetration depth, then the secondary radiation intensity is proportional to the total absorbed energy of X-rays. Computer simulation of the three-wave case (444, 335, Bragg geometry,  $\text{CuK}\alpha$ , Si) shows that the angular dependence of the photoelectron emission yield can be described as a repulsion interaction of two crossing two-wave maxima. A new possibility of observing the two-wave X-ray standing waves is discussed where the angular dependence of the induced second reflected wave with a small intensity is analysed instead of the secondary radiation yield within the total reflection domain for the first reflected wave. (Author abstract) 17 refs.

Kohn, V.G. (I.V. Kurchatov Inst of Atomic Energy, Moscow, USSR). *Phys Status Solidi A* v 106 n 1 Mar 1988 p 31-39.

**095448 GRAZING INCIDENCE X-RAY DIFFRACTION FROM SI WITH AN IMPLANTATION INDUCED AMORPHOUS SURFACE LAYER.** Si single crystals are implanted with As ions of 80 keV to a dose of  $1 \times 10^{15} \text{ cm}^{-2}$ . Under conditions of total external reflection Bragg diffraction of X-rays is measured. Intensity distributions  $I_H$  as a function of angles of grazing exit  $\alpha_H$  are determined with high resolution at different angles of grazing incidence  $\alpha$ . The experimental results are compared to calculations on the basis of dynamical diffraction theory. Complete agreement is achieved only if a variation in  $t_{am}$  of 10 percent across the sample is allowed for. At incidence angles smaller than the critical angle amorphous diffuse scattering is observed. (Edited author abstract) 8 Refs.

**095449 ARGON PLASMA TREATMENT EFFECTS ON  $\text{Si-SiO}_2$  STRUCTURES.** Combining measurements of inversion channel I-V and high frequency C-V characteristics it is shown that argon plasma treatment leads to an increase of positive fixed oxide charge and generation of deep acceptor-type interface states (with a charge density of about  $10^{11} \text{ cm}^{-2}$ ) accompanied by a reduction of the density of shallow acceptor-type interface states and a decrease of the inversion layer mobility. The radiation induced oxide charge is in the order of  $(1-3.5) \times 10^{11} \text{ cm}^{-2}$  depending on the oxide thickness. The mobility decrease and the plasma-introduced charges in the  $\text{Si-SiO}_2$  structures are assumed mainly to be trivalent Si and non-bridging oxygen due to the radiation-induced fracture of weak and strained bonds in the oxide and at the interface. The temperature behavior of the mobility indicates a dominance of Coulomb and surface potential fluctuation scattering. Hence a severe degradation of  $\text{Si-SiO}_2$  structures after low-temperature argon

plasma treatment is found. (Author abstract) 45 refs.

Kassabov, J. (Bulgarian Acad of Sciences, Sofia, Bulg); Atanasova, E.; Dimitrov, D.; Goranova, E. *Solid State Electron* v 31 n 2 Feb 1988 p 147-154.

**095450 DETERMINATION OF  $\text{Si-SiO}_2$  INTERFACE RECOMBINATION PARAMETERS USING A GATE-CONTROLLED POINT-JUNCTION DIODE UNDER ILLUMINATION.** A novel method is presented to determine  $\text{Si-SiO}_2$  interface recombination parameters. The device used is a polysilicon-oxide-semiconductor capacitor with a microscale central junction (a gate-controlled point-junction diode). Data analysis has been performed using a numerical scheme to find a quasi-exact solution for the current combining at the interface. It was found that the interface recombination parameters depend only weakly on trap energy in a wide range around midgap. The cross-section for capturing electrons was found to exceed the cross-section for capturing holes by a factor of  $10^2$  to  $10^3$ . 40 refs.

**095453 PHOTOLUMINESCENCE OF QUASI-ONE DIMENSIONAL AMORPHOUS  $\text{Si}_{1-x}\text{C}_x\text{:H}$  PREPARED BY THE GLOW DISCHARGE METHOD.** Glow discharge deposited  $\text{a-Si}_{1-x}\text{C}_x\text{:H}$  from disilane and acetylene with low substrate temperature has been studied for various gas mixing ratio  $M_g$  by photoluminescence measurement. The spectrum of a-C:H consists of two bands of 2.05 and 1.53 eV peak energies. The band at 2.05 eV shows the molecular-like radiative recombination and is also observed in  $\text{a-Si}_{1-x}\text{C}_x\text{:H}$  above  $m_g=40\%$ . These results are explained by one-dimensional structure constructing from polysilane and polyacetylene. (Author abstract) 12 refs.

**095454 WHY THE PHOTOCONDUCTIVITY DECREASES IN  $\text{a-SiC:H}$  AND  $\text{a-SiGe:H}$  WHEN THE AMOUNT OF ALLOYING INCREASES.** IR, photoconductivity, Raman and photothermal deflection spectroscopy measurements were used to probe the relationship between material quality and the amount of microstructure in glow discharge deposited a-SiC:H and

a-SiGe:H films. We find that the microstructure is directly responsible for the decrease in photoconductivity observed in both alloys as a function of increased alloy content. The microstructure does this by causing a decrease in the steepness of the Urbach tail, thus allowing for an increase in both carrier trapping at the wider band edges and carrier recombination at or near the band tails. (Author abstract) 17 refs.

**095455 HOT-ELECTRON TRAPPING IN THIN LPCVD SiO<sub>2</sub> DIELECTRICS.** The electron-trapping and surface-state generation characteristics of thin LPCVD (liquid-phase chemical vapor deposition) SiO<sub>2</sub> dielectrics have been studied using avalanche hot-electron injection. Layered structures of thermal and LPCVD oxide have been examined as a function of anneal time and temperature. After a 1000°C anneal, bulk trapping in the LPCVD oxide was reduced to levels comparable to those in a high-quality dry thermal oxide. Sensitivity to remaining traps was reduced by the presence of a thermal oxide layer on the semiconductor surface. After a postdeposition anneal, these layered surfaces demonstrated hot-electron performance equal to that of thermal oxide, within measurable limits. Also, layered structures generally demonstrated better resistance to surface-state generation than thermal oxides alone. 12 refs.

## Chemical Vapor Deposition

**095456 LOW TEMPERATURE PYROLYTIC DEPOSITION OF HIGH QUALITY SiO<sub>2</sub>.** A pyrolytic process for the deposition of high quality silicon dioxide at temperatures of 100°-330°C is reported. Deposition is achieved by reacting silane and oxygen in the 2-12 torr pressure range, yielding deposition rates of 140 Å/min at 300°C and 50 Å/min at 120°C. Measurements of refractive index (1.45-1.46), field strength ( $3 \times 10^6$  V/cm), and resistivity ( $10^{13}$ - $10^{16}$  Ω-cm) indicate that the oxides are near-stoichiometric SiO<sub>2</sub>. Fixed oxide charge densities are as low as  $3 \times 10^{10}$  cm<sup>-2</sup> on <111> silicon. This technology appears promising for Group IV and Group III-V device applications. (Author abstract) 22 refs.

**095457 DOWNSTREAM PLASMA INDUCED DEPOSITION OF SiN<sub>x</sub> ON Si, InP, AND InGaAs.** Silicon nitride (SiN<sub>x</sub>) films have been deposited on Si, InP, and In<sub>0.47</sub>Ga<sub>0.53</sub>As using a downstream microwave plasma technique. Active nitrogen from a 2 torr N<sub>2</sub> plasma is used to chemically dissociate SiH<sub>4</sub> at the heated substrate located 60 cm downstream of the discharge. Films 50 nm thick were deposited in the temperature range 250°-400°C with SiH<sub>4</sub> to N<sub>2</sub> ratio of 0.03:1. For films deposited at 300°C, ellipsometer measurements gave a refractive index of  $1.90 \pm 0.05$  and Auger analysis showed an Si to N ratio of 0.71:1 with less than 0.1 atom percent oxygen. IR analysis of the films showed a decrease in the Si-H content after annealing. MIS capacitors were used to evaluate the bulk dielectric and insulator-semiconductor interface properties. C-V measurements were made at 10 MHz, 1 MHz, and 10 kHz. (Edited author abstract) 18 refs.

**095458 FABRICATION OF a-Si:H FILMS BY CO-AXIAL LINE TYPE MICROWAVE HYDROGEN PLASMA CVD.** A double tube coaxial line type microwave plasma CVD system has been developed for a-Si:H film deposition using hydrogen and argon gases with pure SiH<sub>4</sub> gas as the material gas. The film quality was evaluated as a function of the plasma condition. A high-quality film can be fabricated under hydrogen plasma because a large amount of hydrogen radicals covers the film surface, thereby causing a thermal structural relaxation of silane radicals. This relaxation results when the silane radicals increase their surface mobility after the soft landing on the film surface. (Edited author abstract) 25 refs.

## Cleaning

**095460 WAY TO CLEAN WAFERS FAST - WITHOUT OXYGEN.** To speed up the cleaning of metallic contaminants from the critical top layers of a silicon wafer researchers at the Massachusetts Institute of Technology, with help from Texas Instruments Inc., are exploring a promising new method of purifying the material in seconds. To shorten the time needed, the MIT team collects the contaminants around butterfly-shaped deformities in the lattice structure of the silicon itself.

Angiolillo, Paul. *Electronics* v 60 n 18 Sep 3 1987 p 38.

## Crystalline

**095461 PHOTOLUMINESCENCE STUDY OF MICROCRYSTALLINE SILICON.** The photoluminescence characteristics of the crystallized amorphous silicon (microcrystalline Si) prepared by raising the substrate temperature (from 300°C to 520°C) during the deposition of amorphous Si with r.f. GD method are investigated. The luminescence peaks at about 1.35 eV in the photoluminescence spectra similar to a-Si,  $\mu$ -Si films are obtained. It can be concluded from the temperature dependence of the luminescence intensity and the photoacoustic spectra (PAS) that 1) the band tail width is narrowed, which indicates the decrease of the localization of the carriers in an amorphous phase in two-phase  $\mu$ -Si, 2) the dissociation energy of the photoinduced electron-hole pairs in the band tail states is reduced and 3) the non-radiative recombination is increased as the crystallization is enhanced. (Edited author abstract) 13 refs.

**Defects** See Also SEMICONDUCTOR DEVICES, MOS—Analysis.

**095462 ON THE GENERATION AND ANNEALING OF DANGLING BOND DEFECTS IN HYDROGENATED AMORPHOUS SILICON.** We show that, through the diffusive re-arrangement of Si-H bonds, the a-Si:H lattice is able to establish thermal equilibrium

between the densities of band tail trapped charge carriers and dangling bond defects. When this equilibrium is disturbed by changes in temperature, carrier injection or illumination, dangling bond defects have to be generated or annealed out via H-diffusion processes. Based on the concept of charge-induced bond breaking, we develop a mathematical formalism for the diffusive re-arrangement of Si-H bonds and show that our formalism can account for a variety of observations that have been made in the content of defect-generation and annealing experiments. (Author abstract) 26 refs.

**095463 LIGHT-INDUCED METASTABLE DEFECTS IN a-Si:H AS ELUCIDATED BY OPTICALLY DETECTED MAGNETIC RESONANCE MEASUREMENTS AT 2K.** We observed a gradual increase of a nonradiative recombination channel in a-Si:H by strong light exposure at 2 K, i.e., an increase in the intensity of the quenching optically detected magnetic resonance (ODMR) line at  $g=2.005$  and no change of the other quenching lines at  $g=2.004$  and  $g=2.013$ . The sample with previous light soaking at 300 K still showed a degradation of photoluminescence (PL) efficiency as much as that for the sample without previous light soaking, but no obvious change of the quenching ODMR lines. An increase of silicon dangling bond (db) density and the other nonradiative recombination process are suggested to explain the experimental results. (Author abstract) 17 refs.

Han, Daxing (Univ of Tokyo, Tokyo, Jpn); Yoshida, M.; Morigaki, K. *Solid State Commun* v 63 n 12 Sep 1987 p 1083-1086.

## Diffusion

**095464 MICROSTRUCTURE OF RuO<sub>2</sub> LAYER AS DIFFUSION BARRIER BETWEEN Al AND Si SUBSTRATE.** The microstructure of samples consisting of a 40 nm thick RuO<sub>2</sub> film reactively sputtered on a Si <111> substrate and covered with 20 nm of Al (<Si>/RuO<sub>2</sub>/Al) is investigated by high-resolution cross-sectional electron microscopy. The depth distributions of elements are studied by Rutherford backscattering spectrometry and electron probe microanalysis. In the as-deposited sample, the RuO<sub>2</sub>/Al interface is sharp, but a thin (3 nm) SiO<sub>2</sub> layer is observed at the <Si>/RuO<sub>2</sub> interface. After annealing at temperatures ranging from 450 to 700°C for 1-6 h, that layer remains unchanged, but a crystalline compound layer forms at the RuO<sub>2</sub>/Al interface. No diffusion of Si and Al into RuO<sub>2</sub> is detectable. The possible mechanisms for the barrier characteristics are discussed. We believe that the presence of the thin SiO<sub>2</sub> layer and the formation of an additional compound layer is intimately related to the good barrier performance of RuO<sub>2</sub>. (Author abstract) 14 refs.

**Doping** See Also SEMICONDUCTOR DEVICES, MOS—Thin Films; TRANSISTORS, FIELD EFFECT—Ion Implantation.

**095465 EFFECT OF HIGH TEMPERATURE ANNEALING ON THE MICROSTRUCTURE AND THERMOELECTRIC PROPERTIES OF GaP DOPED SiGe.** Annealing of GaP-doped SiGe will significantly alter the thermoelectric properties of the material resulting in increased performance as measured by the figure of merit, Z, and the power factor, P. The microstructures and corresponding thermoelectric properties after annealing in the 1100 to 1300°C temperature range have been examined to correlate performance improvement with annealing history. The figure of merit and power factor were both improved by homogenizing the material and limiting the amount of cross-doping. Annealing at 1215°C for 100 hr resulted in the best combination

of thermoelectric properties with a resultant figure of merit exceeding  $1 \times 10^{-3} \text{ } ^\circ\text{C}^{-1}$  and a power factor of  $44 \text{ } \mu\text{W cm}^{-2} \text{ } ^\circ\text{C}^{-2}$  for the temperature range of interest for space power: 400 to  $100^\circ\text{C}$ . (Author abstract) 14 refs.

**095466 CHARACTERIZATION OF THE HEAVILY (NON-DEGENERATE) BORON-DOPED  $\text{Si-SiO}_2$  INTERFACE.** The influence of doping, crystallographic orientation and oxide thickness on the parameters of the boron-doped  $\text{Si-SiO}_2$  interface up to  $3 \times 10^{18} \text{ cm}^{-3}$  for oxides thermally grown in a wet  $\text{O}_2$  ambient is investigated. The fundamental surface recombination velocity, which is proportional to the product of the density of the effective recombination centers and of the associated capture cross section is nearly constant in the range of doping studied. The fixed-oxide charge density increases with doping concentration; this is probably due to the increasing importance of boron atoms segregating in the oxide and/or to the excess silicon interstitials increasing in density with dopant concentration. (Author abstract) 9 refs.

## Electronic Properties

**095467 ELECTRONIC STRUCTURE OF STRAINED  $\text{Si}_n/\text{Ge}_n(001)$  SUPERLATTICES.** Using the empirical tight binding method, we have investigated the electronic properties of the  $\text{Si}_n/\text{Ge}_n(001)$  strained superlattices as a function of the superlattice periodicity and the band misfit. For  $n \geq 4$  we have found that first and second conduction band states are localized in Si. The hole states localized in Ge appear for  $n \geq 4$ . The difference between the direct and indirect band gaps is reduced from 2.01 eV for bulk Si to 0.01 eV for  $n = 6$  which can be considered to be quasi-direct. For the cases  $n = 6$  and  $n = 8$ , the band gap might become direct for large values of band misfit. (Author abstract) 14 refs.

**095468 NATURE OF TRAPPED HOLE CENTRES (A CENTRES) IN  $\text{a-Si:H}$ : INVESTIGATION OF OPTICALLY DETECTED MAGNETIC RESONANCE AND PHOTOINDUCED ABSORPTION MEASUREMENTS ON  $\text{a-Si:H/a-Si}_{1-x}\text{N}_x\text{H}$  SUPERLATTICES.** The nature of the trapped hole centers (A centers) has been elucidated by optically detected magnetic resonance and photoinduced absorption (PA) measurements on  $\text{a-Si:H/a-Si}_{1-x}\text{N}_x\text{H}$  superlattices. The superlattice films reported here were of two types, i.e.,  $x=0.4$  and  $L_B$  (barrier-layer thickness) = 40 Angstrom and  $x=0.57$ ,  $L_B = 25$  Angstrom with various well-layer thickness,  $L_w$ , ranging from 6 to 36 Angstrom. The ODMR measurements were carried out at 9.6 GHz and 2 K, using a microwave spectrometer whose detail has been described in a previous article. The ODMR signal was detected by monitoring either total emitted light or monochromatized emission light with use of a cooled Ge detector. The optical excitation source was unfocused argon ion laser light at either 514.5 nm or 488 nm, depending on the optical gap energy of the film. The PA measurements were also carried out at 2 K using unfocused argon ion laser light as an excitation light. The results are discussed in terms of a model of self-trapped holes for the A centers. (Edited author abstract) 13 refs.

**095469 HOT ELECTRONS IN  $\text{SiO}_2$ : BALLISTIC TO STEADY-STATE TRANSPORT.** We present experimental and theoretical review of the properties of electron transport in thermally grown  $\text{SiO}_2$ . In thick films ( $\geq 10$

nm), steady-state transport is controlled by polar electron-phonon scattering at electric fields below  $2 \times 10^6 \text{ V/cm}$ . At higher fields, nonpolar scattering prevents the electrons from 'running away' and allows steady-state transport to occur at average electron energies of a few eV. In thinner films ( $\leq 6 \text{ nm}$ ), the 'vacuum emission' technique performed at room temperature and 80 K allows the observation of ballistic transport and phonon replicas, in agreement with Monte Carlo simulations. These results are used to investigate the electron-lattice coupling constants that result from the almost ideal structural and electronic properties of thermally grown  $\text{SiO}_2$  films. (Edited author abstract) 34 refs.

Fischetti, M.V. (IBM, Yorktown Heights, NY, USA); DiMarzio, D.J. *Solid State Electron* v 31 n 3/4 Mar/Apr 1988 p 629-636.

## Growth

**095470 AES AND FACTOR ANALYSIS STUDY OF SILICIDE GROWTH AT THE Pd/c-Si INTERFACE.** The authors measured the evolution of a palladium/silicon interface under consecutive annealing periods, performed at  $200^\circ\text{C}$  in UHV conditions. The interface was analyzed by means of Auger electron spectroscopy combined with factor analysis applied in a sequential way. It was found that silicide appears only after annealing and evolves until all the palladium is consumed. A silicon compound different from silicide, identified as  $\text{Pd}_3\text{Si}$  with  $x < 2$  is found at the Pd/Si and  $\text{Pd}_2\text{Si/Si}$  interfaces, before and after annealing respectively. (Edited author abstract) 13 refs.

Ion Implantation See Also TRANSISTORS, FIELD EFFECT.

**095471 RAPID THERMAL ANNEALING OF SI-IMPLANTED LEC Si-GaAs AND ITS USE FOR GaAs VHSIC.** Rapid Thermal Annealing (RTA) of single and dual Si-implanted Si-GaAs has been investigated using a RF graphite heating apparatus. The Si-GaAs substrate used for direct implant was grown by LEC method. Si ion implant was performed at room temperature. Single implant was made at 100 keV with a dose between  $5 \times 10^{12} \text{ cm}^{-2}$  and  $5 \times 10^{14} \text{ cm}^{-2}$ ; dual implants were at 100 keV and 40 keV energy levels with doses of  $5 \times 10^{12} \text{ cm}^{-2}$  and  $1 \times 10^{14} \text{ cm}^{-2}$ , respectively. The GaAs wafer to be annealed was placed on a Si wafer with the polished surfaces facing each other to reduce the As loss of GaAs. The annealing temperature was between  $900^\circ\text{C}$  and  $1050^\circ\text{C}$  with overall annealing time varying from 5s to 15s. For both single and dual implants good results have been obtained compared with  $\text{SiO}_2$  capped furnace annealing. The dual Si-implanted RTA material has been used for the development of GaAs VHSIC and good results have been obtained. For example, the gate delay of 11-stage ring oscillator can be as small as 75.8 ps and the clock rate of frequency divider can reach 2.1GHz. (Edited author abstract) In Chinese. 2 refs.

W.; Wollschlaeger, K. *Phys Status Solidi A* v 105 n 2 Feb 1988 p 387-396.

## Microstructure

**095473 DISTRIBUTION OF EL2 AND DISLOCATION AND THEIR CORRELATION IN Si-GaAs.** The radial distributions of EL2 concentration, dislocation density and carbon concentration in specimens of different carbon content grown by the LEC method were measured. The distribution of the carbon concentration is random. The average EL2 concentration increases after 2 hour annealing at  $800^\circ\text{C}$  in  $\text{H}_2$  atmosphere. The correlation between the distribution of EL2 and dislocations and the mechanism of annealing are discussed. (Edited author abstract) 21 Refs. In Chinese.

## Photoconductivity

**095475 MEASUREMENT OF THE DENSITY OF ELECTRONIC STATES IN AQUEOUS ELECTROLYTES USING OXIDE-COVERED Pt-SILICIDE ELECTRODES.** A method of overcoming the difficulty in observing charge-transfer-limited current is to use a metal electrode covered with an insulator film which is thin enough to allow direct tunneling of electrons, but thick enough to avoid diffusion-controlled current. In this study an experimental investigation was made of the electrochemical charge transfer kinetics occurring with an oxide-covered Pt-silicide electrode. The effective electronic density states of ions in aqueous electrolytes was determined experimentally for the first time. The results for ferrocyanide ions showed excellent agreement with the classical theory of the Marcus-Gerischer model. 10 refs.

## Physical Properties

**095476 SIMPLE METHOD TO DETERMINE THE  $\text{Si/SiO}_2$  FAST INTERFACE TRAP DENSITY CHANGE AFTER HIGH FIELD STRESS ON SILICON-ON-INSULATOR SUBSTRATES.** A simple method based on quasistatic capacitance-voltage measurements is described to determine the change in the  $\text{Si/SiO}_2$  fast interface trap distribution after high field stress. The method is independent of substrate type and enables the density of states distribution to be determined in the bandgap. However, the absolute energy of the traps is only known within an additive constant of comparable magnitude to the effective flatband voltage. Examples of the method are presented for a nonuniformly doped substrate and a high resistivity silicon-on-sapphire substrate. (Author abstract) 4 refs.

## Pressure Effects

**095477 PRESSURE STUDIES OF QUASI-ONE DIMENSIONAL AMORPHOUS Si:H FILMS.** Pressure dependences of the optical absorption edge and the linear compressibility have been investigated up to approx. 100 kbar for quasi-one dimensional  $\alpha$ -Si:H films prepared by glow-discharge decomposition of disilane. The dependences behave in a different way in the high and low pressure regions. When pressure is lower than approx. 60 kbar, the material is compressed greatly and the pressure coefficient of the energy gap is  $-1 \text{ meV kbar}^{-1}$ . Above this pressure, the material becomes more rigid and the coefficient is  $-8 \text{ meV kbar}^{-1}$ . These results are discussed on the basis of a structural model which assumes a film structure consisting of polysilane molecules and  $\alpha$ -Si clusters. (Author abstract) 10 refs.

Tanaka, K. (Hokkaido Univ, Sapporo, Jpn); Nitta, S. *Solid State Commun* v 66 n 8 May 1988 p 827-830.

## Radiation Effects

**095478 RADIATION HARDNESS PROPERTY OF DRY OXIDE GROWN BY POSTOXIDATION COOLING IN OXYGEN AMBIENT.** The radiation behavior of silicon oxides prepared under various postoxidation conditions is studied by  $^{60}\text{Co}$  irradiation with a total dose of  $10^6$  rad. Before irradiation, it was shown that the sample obtained by postoxidation cooling in  $\text{N}_2 + \text{O}_2$  exhibited more positive initial oxide charges and larger negative charge-temperature instability than that obtained by postoxidation annealing in  $\text{N}_2$ . But after considering the initial oxide field effect on the irradiation result, the former one is less sensitive to irradiation than the latter one. Surprisingly, this hardness ability is significantly enhanced when the orientation of silicon substrate is gradually tilted from [100] to [011]. Possible explanations are given for these observations. It is supposed that the postoxidation cooling in  $\text{N}_2 + \text{O}_2$  provides a possible way for the oxide to become more radiation hard. (Author abstract) 20 refs.

Hwu, Jenn-Gwo (Nat'l Taiwan Univ, Taipei, Taiwan); Fu, Shyh-Liang. *Appl Phys A* v 46 n 3 Jul 1988 p 221-227.

## Spectroscopic Analysis

**095479 OPTICAL MODULATION SPECTROSCOPY IN  $\alpha$ -Si:H AT ROOM TEMPERATURE.** Optical Modulation Spectroscopy was studied at room temperature in three  $\alpha$ -Si:H films with different deposition temperatures. The gap density of states is largely influenced by this parameter. The results may be explained with a sharp distribution of  $\text{D}^0$  (neutral dangling bond) states and a broad distribution of  $\text{D}^-$  (negatively charged dangling bond) states. (Author abstract) 14 refs.

## Stresses See SEMICONDUCTING SILICON—Oxidation.

## Surfaces

**095480 MODIFYING  $\text{SiO}_2$  SURFACE STATE.** A novel technique for modifying  $\text{SiO}_2$  surface state is presented. After the  $\text{SiO}_2$  surface is bombarded by electrons under certain energy, the variation of etching rate is observed. The etch rate of unbombarded  $\text{SiO}_2$  is about 700 - 1000 Å/min. However, no etching is observed for bombarded samples. (Author abstract) 2 refs. In Chinese.

Han, Jieping (Acad Sinica, Beijing, China); Wang, Peida; Xu, Weidong; Jin, Zhongyuan; Chen, Mengzhen. *Pan Tao Ti Hsueh Pao* v 9 n 2 Mar 1988 p 221-223.

## Synthesis

**095481 SILICON CARBIDE FILMS OBTAINED IN A HIGH-FREQUENCY DISCHARGE PLASMA.**

Using IR spectroscopy and ultrasoft X-ray emission spectroscopy, a study was made of silicon carbide films obtained by evaporating quartz in a high-frequency induction discharge plasma at atmospheric pressure. In the general case, the films contain a large number of Si-C, Si-N and Si-O groups. The silicon carbide concentration in these films exceeds 50 wt.% (with organ as the plasma-forming gas). The complex spectral contour of the absorption band, with a maximum at  $825 \text{ cm}^{-1}$  in the IR spectrum of the SiC films, is decomposed into individual components; bands with maxima at 750, 820 and  $940 \text{ cm}^{-1}$  are obtained. 5 refs. In Russian.

**095482 COMPARATIVE AES AND RHEED STUDY OF THE FORMATION OF Pd SILICIDE ON CLEAN AND OXIDE COVERED Si(100) AND (111) SURFACES.** The formation and epitaxial orientation of Pd silicide on clean and native oxide covered Si(100) and (111) surfaces was studied by Auger electron spectroscopy (AES) and reflection high energy electron diffraction (RHEED). Pd was vapor-deposited in UHV onto the substrates up to thicknesses of about 6 nm. On clean Si substrates, ultra thin Pd deposits reacted to form  $\text{Pd}_2\text{Si}$  even at room temperature. However, a polycrystalline structure with very small crystallite sizes was indicated by diffuse ring patterns in RHEED. During annealing of room-temperature deposits of Pd, the (100) and (111) substrates behaved differently. Larger crystallites formed on Si(100), but the films remained polycrystalline, though textured. On Si(111), virtually perfect epitaxial re-orientation of the silicide was found. When the substrates were initially covered with native oxide of about 2 nm thickness, silicide formation started at about  $200^\circ\text{C}$ , resulting in polycrystalline, but strongly textured  $\text{Pd}_2\text{Si}$ . (Edited author abstract) 10 refs.

**095483 CONCENTRATION CHANGES OF Pt AND Si IN A Pt/POLY-Si THIN LAYER SYSTEM BETWEEN  $750$  AND  $1000^\circ\text{C}$ .** A Pt/poly-Si/ $\text{SiO}_2$ /Si(100) multilayer system was annealed at  $750^\circ\text{C}$  in order to grow a PtSi layer on the poly-Si layer. Upon subsequent annealing at  $820^\circ\text{C}$ , the unreacted poly-Si diffuses partly into the PtSi. When equilibrium was reached at  $880^\circ\text{C}$ , the poly-Si and PtSi layers were almost completely separated with the Si nearer to the surface. After annealing at  $1000^\circ\text{C}$  for 10 min, the Pt and Si concentrations were constant throughout the top layer. (Author abstract) 7 refs.

**095484 D.C. CONDUCTION IN THIN FILMS OF  $\text{SiO}/\text{In}_2\text{O}_3$  BEFORE AND AFTER ELECTROFORMING.** Electrical measurements on thin co-evaporated  $\text{SiO}/\text{In}_2\text{O}_3$  films before and after electroforming are reported. The high-field conduction (expressed in terms of circulating current  $I_c$  and bias voltage  $V_b$ ) in thin film sandwich structures of Al-SiO/ $\text{In}_2\text{O}_3$ -Al and Cu-SiO/ $\text{In}_2\text{O}_3$ -Cu is found to obey a relation of the form  $\log I_c \propto V_b^{1/2}$ . The electroformed samples show voltage-controlled negative resistance, voltage memory, thermal-voltage memory and pressure-voltage memory effects and the results are explained in terms of the filamentary model of electrical conduction. (Author abstract) 14 refs.

**095485 ELECTRICAL CONTACTS TO BETA SILICON CARBIDE THIN FILMS.** Ohmic and rectifying electrical contacts to n- or p-type semiconducting  $\beta$ -SiC thin films were developed and characterized. Upon an-

nealing for 300s at  $1523 \text{ K}$ , Ni, Au-Ta, and Cr were ohmic on n-type material.  $\text{TaSi}_2$ , similarly heated to  $1123 \text{ K}$ , and as-deposited Al also showed ohmic character.  $\text{TaSi}_2$  had the lowest room-temperature contact resistivity of  $2.0 \times 10^{-2} \Omega\text{-cm}^2$ . For p-type  $\beta$ -SiC, Al-Ta $\text{Si}_2$  annealed for 1800s at  $1473 \text{ K}$  and Al annealed for 180s at  $1150 \text{ K}$  exhibited ohmic behavior. Al was the better of the two, having a room temperature contact resistivity of  $3.1 \times 10^{-2} \Omega\text{-cm}^2$ . High-temperature measurements of Al and  $\text{TaSi}_2$  contacts showed that these contacts are stable during electrical operation to at least  $673 \text{ K}$  for 8h in air. At this temperature the contact resistivity of  $\text{TaSi}_2$  and Al on  $\beta$ -SiC decreased by a factor of two and ten, respectively. Contacts of Au were shown to be rectifying on n-type  $\beta$ -SiC with a barrier height of  $1.20 \text{ V}$ . (Author abstract) 23 refs.

**095486 MICROPORE DENSITY IN  $\alpha$ -Si:H AND  $\alpha$ -Si:HCl FILMS.**  $\alpha$ -Si:H films deposited from various silane-containing gas mixtures have been studied regarding their porosity. Micropore densities of  $2.0 \times 10^2 \text{ cm}^{-2}$ ,  $5.0 \times 10^3 \text{ cm}^{-2}$  and  $5.0 \times 10^4 \text{ cm}^{-2}$  were determined for  $\alpha$ -Si:H:Cl,  $\alpha$ -Si:H(H+2) and  $\alpha$ -Si:H(Ar) films, respectively. It is suggested that these values correlate with the structural properties of the films, so that  $\alpha$ -Si:H:Cl films seem to be the most uniform on the microstructural scale. (Author abstract) 7 refs.

**095487 PREPARATION AND TRANSPORT PROPERTIES OF AMORPHOUS SiGe ALLOYS.** The efficiency of solar energy conversion into electric power by means of the photovoltaic effect depends crucially on the bandgap of the light-absorbing semiconductor. It can be tailored to an optimum value with silicon-germanium alloys, whose bandgap can be varied along with their composition between  $1.8 \text{ eV}$  and  $1.0 \text{ eV}$ . These alloys were deposited as thin films on glass substrates by RF glow discharge. Their transport properties (mobility and lifetime) were determined by stationary and transient photoconductivity (time-of-flight technique). (Author abstract) 10 refs.

**095488 POST-NITRIDATION ANNEALING - AN EFFECTIVE METHOD TO IMPROVE THE CHARACTERISTICS OF ULTRATHIN THERMAL NITRIDED OXIDE FILM.** The characteristics of ultrathin (approx. 100 Å) thermal nitrided  $\text{SiO}_2$  film was investigated. A new post-nitridation annealing technique was presented. The obtained thin film has several advantages compared to the thin  $\text{SiO}_2$  film, such as excellent oxidation-resistant characteristics; less positive charge and electron trap generation under high electric field stress; superior electrical breakdown characteristics; better irradiation-hard performance, etc. Its fixed charge and interface density are comparable to those of thin  $\text{SiO}_2$  film. It is a kind of ultra thin dielectric film of high performance. (Edited author abstract). 10 Refs. In Chinese.

**095489 HYDROGENATED AMORPHOUS SILICON FILMS DEPOSITED BY DC PLANAR MAGNETRON REACTIVE SPUTTERING.** Reactive sputtering has the advantage in hydrogenated amorphous silicon ( $\alpha$ -Si:H) deposition that it permits wide control of the hydrogen content in the films. This paper describes  $\alpha$ -Si:H films with high photo-to-dark conductivity ratios ( $10^5$ - $10^6$ ) and low midgap densities of states (approx.  $5 \times 10^{15} \text{ cm}^{-3}\text{-eV}^{-1}$ ) that we have deposited by DC

magnetron sputtering onto borosilicate glass substrates. Particular attention is given to the influence of the hydrogen partial pressure on the film properties such as the hydrogen content and bonding, the photo- and dark-conductivity, and the optical bandgap. (Edited author abstract) 30 refs.

## Vapor Deposition

**095490 PHOTOENHANCED DEPOSITION OF SILICON OXIDE THIN FILMS USING A NOVEL WINDOWLESS INTERNAL NITROGEN DISCHARGE LAMP.** This paper reviews the production of silicon oxide thin films using a novel photoenhanced deposition technique incorporating a windowless nitrogen discharge lamp contained within the deposition vessel. The use of an internal lamp obviates the need for a window between the lamp and reaction chamber and thus overcomes the problems of attenuation of short wavelength ultraviolet radiation by the window. Thin films of silicon oxide have been deposited onto single crystal silicon wafers from nitrous oxide-silane gas mixtures. Thin film transistors (TFTs) have been fabricated using the material (and an active layer of amorphous silicon deposited in the same system) and characteristics of these TFTs are also presented. (Edited author abstract). 14 refs.

## SEMICONDUCTING SILVER COMPOUNDS

### Ionic Conduction

**095491 SOUND VELOCITY IN SILVER CHALCOGENIDES.** In this note, the authors investigate the sound propagation in a silver chalcogenide using a continuum model and calculate the shift of sound velocity, which is caused by the deviation from a stoichiometric ratio. It is shown that the deviation dependences due to excess ions and electrons are different. 9 Refs.

Kobayashi, M. (Niigata Univ, Niigata, Jpn); Yonashiro, K. *Solid State Ionics* v 27 n 3 Jul 1988 p 169-174.

### Optical Properties

**095492 NEGATIVE PHOTOCONDUCTIVITY IN AgGaSe<sub>2</sub> SINGLE CRYSTALS DUE TO THE NEGATIVE PHOTOGALVANIC EFFECT.** The report deals with the results of an investigation of the negative photogalvanic effect (NPGE) observed by the authors for the first time, and the impact of this effect on the negative photoconductivity (NP) in AgGaSe<sub>2</sub> single crystals. In order to study the photogalvanic effect, the crystals were exposed to linearly polarized light. In the wavelength range where NPGE are observed, the NPGE modes coincide with the infrared quenching of intrinsic photoconductivity. Hence it can be concluded that the negative PGE and negative PC are likely to be associated with R-centres of slow recombination characterized by energies of  $E = 0.68$  eV. 13 Refs.

### Spectrum Analysis

**095493 SHALLOW BOUND EXCITONS IN SILVER HALIDES.** Luminescence and excitation experiments in AgBr and AgCl are described and interpreted for weakly bound excitons associated with divalent metal and chalcogen impurities like Cd<sup>2+</sup>, S<sup>2-</sup> etc. In the analysis, data on corresponding donors are used and central cell effects considered. The results are essentially in agreement with the assumption of recombination of (D<sup>0</sup>, X) complexes. Additional results are presented for crystals containing higher impurity concentrations or thermally treated. Experiments on excitons weakly bound at randomly fluctuating potentials due to compositional disorder in AgBr<sub>1-x</sub>Cl<sub>x</sub> alloys are also reported. Temperature variation, time-resolved resonant light scattering and hydrostatic pressure are employed to study emission specific to the alloy, the results proving that it is due to this type of localized exciton state. (Author abstract) 35 refs.

### Thermal Effects

**095494 ANOMALOUS TEMPERATURE DEPENDENCE OF FUNDAMENTAL GAP OF AgGaS<sub>2</sub> AND AgGaSe<sub>2</sub> CHALCOPYRITE COMPOUNDS.** We have studied the temperature variation of the fundamental gap energy of the chalcopyrite-like ternary semiconductors AgGaS<sub>2</sub> and AgGaSe<sub>2</sub> from reflectivity measurements performed between 5 K and room temperature. The temperature evolution of the gap energy is found to be different from that observed for the II-VI and III-V zincblende-like binary semiconductors. The temperature coefficients are positive under 80 K and negative above 100 K with values smaller than those encountered for the II-VI and III-V binaries. Results are discussed taking into account the hybridization between the d orbitals of Ag and the p orbitals of anion (S or Se). (Edited author abstract) 20 refs.

### Thin Films

**095495 LATTICE CONTRACTION IN SILVER MONOLAYERS.** Ag films were prepared by evaporation onto (Al(111) at 520 K and studied by Spot-Profile-Analysis-LEED (SPA-LEED). The Ag monolayer grows pseudomorphically i.e. its lattice constant is contracted by 0.9% with respect to bulk Ag. With the onset of cluster growth in the second layer, the monolayer is contracted by 3.4%. At higher Ag coverages the contraction within the monolayer, which still exists besides three-dimensional clusters, reaches 5.4%. (Author abstract) 14 refs.

## SEMICONDUCTING TELLURIUM

### Amorphous

**095496 STUDY OF CRYSTALLIZATION IN AMORPHOUS TELLURIUM FILMS USING RESISTIVITY MEASUREMENTS.** A rapid and drastic decrease in resistivity as a result of the crystallization of amorphous tellurium films deposited onto a glass substrate at 10-40°C was measured. On combining the above results with a model proposed for the change in resistivity of the crystallizing film, the activation energy for crystallization was evaluated to be 0.86 eV for pure tellurium films. A higher value of the activation energy was obtained for

gold-nucleated tellurium films. (Author abstract) 10 refs.

### Mass Transfer

**095500 MASS TRANSFER OF HgTe IN THE SYSTEMS HgTe-NH<sub>4</sub>Br(D).** The process of mass transfer of HgTe in the closed systems HgTe-NH<sub>4</sub>Br and HgTe-NH<sub>4</sub>I is considered using a one-dimensional model of diffusion in a multicomponent gaseous mixture. It is assumed that transfer of material occurs between opposite ends of a quartz vial with a temperature gradient. A theoretical and experimental study of the rate of mass transfer of HgTe in these systems for temperature regimes of 743-753 K and 786-801 K showed that mass transfer of HgTe has a diffusion character. In Russian. 12 refs.

## Thin Films

**095501 PYROELECTRICITY OF Cd-DOPED TEL-LURIDE THIN FILM.** The crystalline structure, electrical conductivity and pyroelectricity of freshly prepared  $\text{Hg}_{0.7}\text{Cd}_{0.3}\text{Te}$  thin film have been investigated in detail. In the initial heating stages, the pyroelectric current slowly falls, followed by abrupt decreases corresponding to the breaks in the curves at temperatures depending on the poling temperature, as a general trend in common. Thus 70° is the best poling temperature for attainment of a high generated pyroelectric current, holding up to relatively high working temperatures for the investigated  $\text{HgCdTe}$  films in the electronic and engineering industries. 13 Refs.

See Also GAS ANALYSIS—Sensors; HYDROGEN—Sensors; SOLAR CELLS.

## Crystallization

**095502 EFFECT OF Sn/Sb RATIO IN DETERMINING CRYSTALLITE SIZE OF  $\text{SnO}_2\text{-Sb}_2\text{O}_5$  SEMI-CONDUCTORS.** Six  $\text{SnO}_2\text{-Sb}_2\text{O}_5$  semiconductors with different Sn/Sb ratios were prepared by the gel method. The samples, heated at different temperatures in the range 250 to 1100°C, were characterized by X-ray analysis, surface area determination, TG-DTA studies and SEM observations. Results indicate that the crystallite size of  $\text{SnO}_2$  doped by antimony oxide is affected by the Sb/Sn ratio, smaller crystallites being obtained at lower antimony oxide loadings. The presence of a  $\text{Sb}_2\text{O}_4$  phase separated from  $\text{SnO}_2$  and the effect of antimony doping on  $\text{SnO}_2$  are the main parameters ruling  $\text{SnO}_2$  crystallite dimensions. (Author abstract) 13 Refs.

Carturan, G. (Univ of Trento, Trento, Italy); Giordano Orsini, P.; Scardi, P.; Di Maggio, R. *J Mater Sci* v 23 n 9 Sep 1988 p 3156-3160.

## Defects

**095503 INVESTIGATIONS OF THE BULK DEFECT CHEMISTRY OF POLYCRYSTALLINE TIN (IV) OXIDE.** The bulk defect chemistry of polycrystalline  $\text{SnO}_2$  has been investigated systematically by impedance spectroscopy. Nominally pure and In- and Sb-doped materials were shown to be stable in the rutile structure over the entire temperature range (500-900°C). Lattice constants were determined as a function of temperature. Defect chemistry can be described consistently by assuming fully ionized oxygen vacancies and conduction electrons as native defects. In the  $\text{O}_2$  partial pressure range between 0.02 and 1 bar, intrinsic behavior was observed with a characteristic exponent of  $-1/6$  of  $T > 800^\circ\text{C}$  in nominally pure oxides, whereas at lower temperatures acceptor impurities dominate the conductivity with a characteristic exponent of  $-1/4$ . (Edited author abstract) 21 refs.

Maier, J. (Max-Planck-Institut fuer Festkoerperforschung, Stuttgart, West Ger); Goepel, W. *J Solid State Chem* v 72 n 2 Feb 1988 p 293-302.

## Doping

**095504 CHEMICAL REACTION IN SnTe-BASED SOLID SOLUTIONS IN THE Sn-In-Te SYSTEM.** The results of a theoretical calculation of the concentration dependences of the elementary-cell parameter in various solid solution models were compared with experimental data. It was found that in SnTe-based solid solutions doped with In a deviation from stoichiometry leads to a qualitative change in the structure of the solid solution which is related to a chemical reaction between In atoms and atoms of the matrix to form  $\text{In}_2\text{Te}_3$  complexes. In Russian. 10 refs.

Gorne, G.V.; Zhigareva, N.K.; Ivanova, A.B.; Rogacheva, E.I. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 8 Aug 1987 p 1298-1302.

**095505 DOPING TIN-OXIDE FILMS BY ION IMPLANTATION.** A postdeposition method of doping tin-oxide ( $\text{SnO}_2$ ) films that includes ion implantation and a subsequent anneal has been developed. The method offers the advantage of being simpler and more reproducible than in situ doping techniques. Electrical conductivity can be controlled by adjusting dose and energy. Annealing at 700°C or above for 30 min is adequate to activate the dopants. Diffusion of the dopants such as phosphorus, arsenic, and fluorine in tin oxide is negligible at 900°C or below. Thus dopant distribution is essentially dependent on implant straggle. Electrical conductivity of 400  $\text{mho-cm}^{-1}$  can be routinely obtained with phosphorus implant. The highest conductivity achieved was 700  $\text{mho-cm}^{-1}$  with a combination of phosphorus and  $\text{BF}_2$  implants. (Author abstract) 4 refs.

## Electric Conductivity

**095506 MECHANISMS OF DETECTION ON TIN OXIDE GAS SENSORS.** One of the most critical constraints in the full exploitation of automation in a variety of technological applications is the availability of suitable sensors. The design, fabrication and testing of such devices is therefore a compulsory prerequisite. Besides, the development at industrial level of these kind of devices could not be fulfilled unless reliable and low cost sensors are available, which must be selective to a variety of chemical species present in gas phase. In this paper, we intend to show a review of some important mechanisms of detection in these kind of sensors. Some data about accuracy, selectivity, response time and limits of detecting species are also reported. Finally, two methods of obtaining sensors are also reported; the first consists of a pyrolysis of organometallic compounds and the latter evaporation of metallic tin followed by a controlled oxidation process. (Author abstract) 11 refs.

## Electric Properties

**095508 VARIATION IN ELECTRICAL PROPERTIES OF SnTe THIN FILMS WITH SUBSTRATE TEMPERATURE.** The influence of substrate temperature (300 to 460 K) on the electrical resistivity and thermoelectric power of thin films of SnTe and SnTe doped with 10% excess tin was investigated. The observed variation cannot be attributed to the improvement in crystallinity alone. The results are explained by considering the reduction in carrier concentration and the two-valence band structure of SnTe. (Author abstract) 13 refs.

Ganesan, N. (Indian Inst of Technology, Madras, India); Sivaramakrishnan, V. *Phys Status Solidi A* v 105 n 2 Feb 1988 p 461-466.

**095509 EFFECT OF EXCESS TIN ON THE ELEC-**

**TRICAL PROPERTIES OF SnTe THIN FILMS.** The influence of temperature and thickness on the electrical transport properties of 10% excess tin-doped polycrystalline SnTe thin films were investigated. From the observed variation of electrical resistivity and Seebeck coefficient it is concluded that the material exhibits a p-type degenerate behavior. Using the size effect data, different physical parameters such as Fermi energy, effective mass and scattering parameter were evaluated and compared to understand the effect of excess tin. (Author abstract) 33 refs.

Ganesan, N. (Indian Inst of Technology, Madras, India); Sivaramakrishnan, V. *J Mater Sci* v 23 n 4 Apr 1988 p 1237-1242.

## Optical Properties

**095510 OPTICAL PROPERTIES OF THE ALLOY SYSTEM SnTe-GeTe FROM REFLECTANCE MEASUREMENTS.** The reflectance spectra of bulk samples of the alloy series  $\text{Sn}_{1-x}\text{Ge}_x\text{Te}$  are measured at room temperature in the wavelength range 0.2 to 50  $\mu\text{m}$ . The principal optical constants are obtained using Kramers-Kronig analysis. The variations of the optical dielectric constant, the carrier effective mass, the optical mobility, and the optical energy gap are given as functions of the alloy fraction x. For the Sn-rich alloys ( $x < 0.3$ ) the energy gap and the dielectric constant do not follow the trends established for the series at the Ge-rich side, and are possibly related to the cubic-rhombohedral phase transition that occurs in this system. The mobility and effective mass, though, behave reasonably for all alloy fractions. (Author abstract) 37 refs.

Lewis, J.E. (State Univ of New York, Plattsburgh, NY, USA). *Phys Status Solidi B* v 143 n 1 Sep 1987 p 307-315.

**095511 OPTICAL PROPERTIES OF BROMINE-DOPED  $\text{SnO}_2$  COATINGS FOR SOLAR APPLICATIONS.** Bromine doped  $\text{SnO}_2$  coatings were prepared using spray pyrolysis. The absorption coefficient is calculated in the fundamental absorption region. The absorption coefficient data are analysed and interpreted in terms of direct and indirect allowed transitions. Solar spectrum transmittance, reflection coefficient, refractive index, and figure of merit are estimated. (Author abstract) 16 Refs.

Abass, A.K. (Univ of Basrah, Basrah, Iraq); Al-Liabi, N.A.; Taha, W.A. *Phys Status Solidi A* v 106 n 2 Apr 1988 p 613-618.

## Phase Transitions

**095512 EFFECTS OF A DEVIATION FROM STOICHIOMETRY ON THE MOSSBAUER PARAMETERS OF  $\text{Sn}_{0.8}\text{Ge}_{0.2}\text{Te}$  DURING THE PHASE TRANSITION.** The system of solid solutions ( $\text{Sn}_{0.8}\text{Ge}_{0.2}$ ) $_{1-y}\text{Te}_y$  with the values of  $y=0.499$ ; 0.505; 0.510 is investigated by means of the Mossbauer effect on the  $^{119}\text{Sn}$  nucleus within the temperature range 160 to 300 K. The effective Debye temperature and mean-square displacements of tin atoms from equilibrium are calculated. In the region of phase transition (about 200 K) fractures on the temperature dependencies of the isomer shift and Debye temperature are observed, while no anomalies of the Mossbauer effect probability are noticed. No quadrupole interaction is observed with the symmetry decrease in the lattice. A correlation between the isomer shift and interatomic distance is revealed. The ionicity of the chemical bond in the system  $\text{Sn}_x\text{Ge}_{1-x}\text{Te}$  is  $\approx 54$  percent when  $x=0.9$ , and about 40 percent when  $x=0.1$ . (Author abstract) 20 Refs.

## Photoconductivity

**095513 DYE SENSITIZATION OF VAN DER WAALS SURFACES OF  $\text{SnS}_2$  PHOTOANODES.** The sensitization of the Van Der Waals surface of  $\text{SnS}_2$  ( $E_g =$

2.22 eV) with over 30 different dyes is studied. The van der Waals surface of this material has several advantages of studying sensitization. It is renewable via cleavage and lacks an oxide layer under ambient conditions. The relevance of the electrochemical properties of the dyes to their sensitization behavior is discussed. Adsorption isotherms for many of the dyes were measured by relating quantum yield for electron injection to surface coverage. Both J and H aggregates and monomeric dye species sensitize n-SnS<sub>2</sub>. The photocurrent-voltage behavior of the dye is interpreted by using Spilner's theory of electron injection into semiconductors. Sensitized photocurrents are also studied as a function of light intensity and supersensitizer concentration to aid the qualitative theoretical analysis. Several unusual effects associated with the layered structure of the semiconductor are observed including dye intercalation, total internal reflection of the incident light, and surface phase changes. (Author abstract). 25 Refs.

## Preparation

**095514 PREPARATION AND ELECTROCHEMICAL BEHAVIOUR OF SOME METAL OXIDE FILMS.** Antimony, tin and titanium oxides are very attractive materials for spectroscopic studies, solar energy applications and other industrial purposes. In this work oxide films of these metals were prepared on glass, glassy carbon or platinum using a combined chemical vapor deposition-spraying technique. The variation in the physical properties of the film with its thickness and preparation parameters was studied. The electrochemical properties of the prepared electrodes were studied in different redox systems. The charge transfer reaction between the oxide film electrode and the redox electrolyte seems to occur via electron tunnelling through the barrier formed by the space charge layer of the semiconducting oxide. (Author abstract) 22 refs.

## Switching

**095515 MECHANISM FOR NONLINEAR I - V BEHAVIOUR AND THE TEMPERATURE DEPENDENCE OF THRESHOLD SWITCHING IN THE Se-Te-Sn SYSTEM.** The nonlinear I-V behavior and threshold switching of the bulk Se-Te-Sn system have been experimentally studied at various temperatures. It is observed that the curves are linear for low voltages and become superlinear at higher voltages. After a certain voltage  $V_{th}$ , the current through the material shoots to a very high value and the potential across the material drops to a low value. It is also found that there is a decrease in  $V_{th}$  with increase in percentage of tin and temperature. An attempt is made to explain the nonlinear I-V behavior and threshold switching on the basis of a microcrystallite model. A study of Se-Te-Sn system reveals that our results are in concurrence with the theoretical predictions. (Author abstract). 24 Refs.

## Synthesis

**095516 PYROELECTRIC PROPERTIES OF Sn<sub>2</sub>P<sub>2</sub>S<sub>6</sub> CRYSTALS.** A study was made of the pyroelectric properties of crystals of the ferroelectric semiconductor Sn<sub>2</sub>P<sub>2</sub>S<sub>6</sub>. It was established that at room temperature the pyroelectric properties of these crystals are comparable to those of the most widely known pyroactive materials. It is shown that variations of the technological conditions of growth of the crystals affect the stability of their domain structure. 16 refs. In Russian.

**095517 STRUCTURAL DETERMINATION AND TRANSPORT PROPERTIES OF A NEW PHASE WITH APPROXIMATE COMPOSITION Sn<sub>1.2</sub>Ti<sub>0.8</sub>S<sub>3</sub>.** A new compound, Sn<sub>1.2</sub>Ti<sub>0.8</sub>S<sub>3</sub>, has been characterized. The unit cell is orthorhombic, space group Pnma, a = 8.899(4) Å, b = 3.605(2) Å, c = 13.506(6) Å. Its crystal structure has been determined and yielded a reliability R factor of 0.025. This structure is reminiscent of that of Sn<sub>2</sub>S<sub>3</sub>, where part of Sn IV has been substituted with Ti. The band gap determined from electrical conductivity is found to be 0.05 eV. (Edited author abstract) 10 refs.

## Thin Films

**095518 THICKNESS DEPENDENCE OF H<sub>2</sub> GAS SENSOR IN AMORPHOUS SnO<sub>x</sub> FILMS PREPARED BY ION-BEAM SPUTTERING.** Amorphous semiconducting SnO<sub>x</sub> films were deposited by ion-beam sputtering on sintered alumina substrates. Amorphous film sensors were prepared by annealing the films at 300°C for 2 h in air. The thickness dependence of resistivity and hydrogen gas sensitivity were measured at 150°C over the thickness range ca. 1 to 700 nm. A resistivity maximum was observed in ultrathin films. Resistivity increased by three orders of magnitude with increasing film thickness from 0.9 to 7.4 nm and then decreased by five orders of magnitude from 7.4 to 35 nm. Ultrathin film sensors showed sensitivity maxima around a thickness of 10 nm. Sensitivity and resistivity of ultrathin films were significantly influenced by the thermal expansion coefficient and the surface state of the substrate. (Author abstract) 15 refs.

**095519 HIGHLY CONDUCTING AND TRANSPARENT SnO<sub>2</sub> THIN FILMS PREPARED BY RF MAGNETRON SPUTTERING ON LOW-TEMPERATURE SUBSTRATES.** Highly conducting and transparent thin films of undoped tin oxide (SnO<sub>2</sub>) are prepared on unheated substrates (<90°C) by rf magnetron sputtering under an applied external dc magnetic field. The lowest resistivity obtained is  $1.9 \times 10^{-3} \Omega \text{cm}$ . The SnO<sub>2</sub> films with a sheet resistance below 200  $\Omega/\text{sq}$  and an average visible transmittance (between 400 and 700 nm) above 85%, and below 300  $\Omega/\text{sq}$  and above 80% (including organic film substrate) can be obtained for the films deposited on glass substrates and organic film substrates, respectively. (Author abstract) 18 refs.

**095521 CORRELATION BETWEEN THE 1.1 AND 1.45 eV EMISSION BANDS AND THE F<sup>+</sup> OPTICAL ABSORPTION BANDS IN ZnS CRYSTALS.** Zinc sulfide crystals are fired successively in a Zn liquid at 1184°C and annealed isochronally. The emission spectra between 700 and 1200 nm and the optical absorption bands ascribed to F<sup>+</sup> centers are measured in the specimens. The Zn treatments introduce emission bands with peaks at 1.1 and 1.45 eV, which are reported by other workers. These bands are annealed in company with F<sup>+</sup> centers. Therefore it is proposed that these emission bands are due to F<sup>+</sup> centers. (Author abstract) 21 refs.

**095522 PHOTOCHEMISTRY AND RADIATION CHEMISTRY OF COLLOIDAL SEMICONDUCTORS. 23. ELECTRON STORAGE ON ZnO PARTICLES AND SIZE QUANTIZATION.** Improved methods for the preparation of colloidal ZnO solutions of different particle size are described, and the relation between absorption threshold and particle size is reported. CH<sub>2</sub>OH radicals, radiolytically generated, transfer electrons to ZnO particles. The electrons are long-lived and cause a substantial blue shift of the absorption spectrum of ZnO in a wavelength range of 60 nm below the threshold. The wavelength of maximum bleaching is shifted to shorter wavelengths with decreasing particle size (size quantization effect). Maximum bleaching occurs with a negative absorption coefficient of  $1.1 \times 10^5 \text{ M}^{-1} \text{cm}^{-1}$ . Electrons are also stored upon UV illumination of colloidal ZnO. The stored electrons react rather slowly with oxygen, the rate constant becoming lower with increasing particle size, and more rapidly with peroxy radicals. (Author abstract) 17 refs.

## Charge Carriers

**095523 CARRIER CONCENTRATION AND TRANSPORT IN Hg<sub>1-x</sub>Zn<sub>x</sub>Te FOR x NEAR 0.15.** Experimental measurements of concentration and mobility for as-grown Hg<sub>1-x</sub>Zn<sub>x</sub>Te, and after 'stoichiometric' annealing, are presented. Results are presented on the kinetics of changes in conductivity type and mobility in both types. A comparison of experimental mobility values with calculated ones indicates that the usual Kane model describes fairly well the structure of the electronic states in the conduction band, although the impurity concentration of the samples studied remains high, and since no effective mass measurement has been performed at the present time. 22 refs.

## Chemical Vapor Deposition

**095524 GROWTH RATE ENHANCEMENT BY XENON LAMP IRRADIATION IN ORGANOMETALLIC VAPOR-PHASE EPITAXY OF ZnSe.** The growth rate of ZnSe in organometallic vapor-phase epitaxy (OMVPE) using dimethylzinc (DMZ) and dimethyl-

selenide (DMSe) as the source materials was substantially increased by irradiation from a xenon lamp. The growth temperature was reduced from 500°C to 300°C by keeping a constant growth rate of 1-2  $\mu\text{m}/\text{h}$ . Promotion of surface reaction due to irradiation was considered as one of the factors for the growth rate enhancement. The density of defects which causes deep level emissions was also successfully reduced. We suggest that this technique is very effective to obtain high-quality epilayers. (Author abstract) 10 refs.

**095525 EFFECTS OF LATTICE MISMATCH ON CRYSTALLOGRAPHIC PROPERTIES OF ZnS GROWN ON GaP AND GaAs BY MOCVD.** The unusual phenomenon that largely lattice-mismatched ZnS layers grown on GaAs by MOCVD show better surface morphology and crystalline quality than less mismatched ZnS layers on GaP has been investigated by X-ray diffraction measurements. The results indicate that this phenomenon can be ascribed to the strain-relaxation taking place at an earlier stage of epitaxial growth on GaAs than on GaP substrates. (Edited author abstract) 10 refs.

**095526 PHOTOLUMINESCENCE PROPERTIES OF LI-DOPED ZnSe FILMS GROWN BY METAL-ORGANIC CHEMICAL VAPOR DEPOSITION.** Lithium-doped ZnSe films have been grown by atmospheric metalorganic chemical vapor deposition. Dimethylzinc and dimethylselenide were used as source materials and cyclopentadienyl lithium was used as a dopant. The films have been characterized by a low-temperature photoluminescence. It is shown that the lithium acts as a shallow acceptor in ZnSe with an activation energy of about 101-118 meV. Furthermore, it is shown that the intensity of emission from deep centers, such as so-called self-activated and copper-green emission, is remarkably reduced in lithium-doped ZnSe films. (Author abstract) 10 refs.

**095527 ZnTe LAYERS GROWN ON GaAs SUBSTRATES BY LOW PRESSURE MOCVD.** ZnTe epitaxial layers have been grown on [001] oriented GaAs substrates by low pressure MOCVD. All ZnTe layers grew in the [001] direction with a slight misorientation with respect to the underlying substrate. The layers exhibited an elongated surface structure directed along the [110] direction. The FWH value of the rocking curves was found to reduce with increasing layer thickness, saturating toward the value of 250°. Beyond approximately 2.5  $\mu\text{m}$  the layer quality does not improve very much with increasing thickness. (Author abstract) 17 refs.

Shtrikman, Hadas (Soreq Nuclear Research Cent, Yavne, Isr); Raizman, A.; Oron, M.; Eger, D. *J Cryst Growth* v 88 n 4 May 1988 p 522-526.

**095528 EFFECT OF ANNEALING ON PHOTOLUMINESCENCE PROPERTIES IN Ar<sup>+</sup>-ION IRRADIATED MOCVD-GROWN ZnSe FILMS.** Ion irradiation and subsequent thermal annealing effects have been investigated on photoluminescence properties at 4.2 K of ZnSe films grown on (100) GaAs and Ge substrates by metalorganic chemical-vapor deposition (MOCVD). After irradiation of Ar<sup>+</sup>-ion beams with a total dose of about 10<sup>15</sup> cm<sup>-2</sup> at 50 KeV, the deep-level emission bands newly appear in the vicinity of about 570 nm, while the excitonic emission lines become extremely weak in intensity or vanish completely. The photoluminescence spectra in ZnSe/Ge are almost completely recovered by annealing at 350°C. On the contrary, in the case of ZnSe/GaAs, the deep-level emission bands around 570

nm become much greater in intensity after the anneal. It is suggested that the 550, 570 and 600 nm bands which occur in the irradiated ZnSe/GaAs, are derived from complex defects associated with radiation-induced Zn vacancies and/or donor impurities out-diffused from the substrate. (Edited author abstract) 8 refs.

Sekoguchi, Maki (Osaka Univ, Suita, Jpn); Taguchi, Tsunemasa; Hiraki, Akio. *Jpn J Appl Phys Part 2* v 27 n 4 Apr 1988 p 699-701.

**095529 EXCITONIC AND EDGE EMISSIONS IN MOCVD-GROWN ZnS FILMS AND ZnSe-ZnS SUPERLATTICES.** Excitonic lines and edge-emission bands in metalorganic chemical vapor deposition (MOCVD) heteroepitaxially-grown ZnS films on (100) GaAs substrates have been extensively investigated at 4.2 K using He-Cd (325 nm) and Xe-Cl excimer (308 nm) lasers. Distinct edge-emission bands were observed; the LO-phonon-replicated 3.641 and 3.666 eV bands are ascribed to a donor-acceptor pair and free-to-bound acceptor transition, respectively, from time-resolved spectral measurements. The Na acceptor level is tentatively assigned to be about 170 meV above the valence band. ZnSe-ZnS and ZnSe-ZnS<sub>0.99</sub> superlattices, which were for the first time prepared by low-pressure MOCVD, have been characterized by the well-width dependence of the excitonic lines and by optical absorption. We observed heavy-hole and light-hole excitons in the absorption spectra of the ZnSe-ZnS superlattices. (Author abstract) 11 refs.

Kawakami, Yoichi (Osaka Univ, Suita, Jpn); Taguchi, Tsunemasa; Hiraki, Akio. *J Cryst Growth* v 89 n 2-3 Jun 1988 p 331-338.

**095530 ELECTRICAL AND OPTICAL PROPERTIES OF DONOR DOPED ZnS FILMS GROWN BY LOW-PRESSURE MOCVD.** The growth and properties of donor impurity doped ZnS films prepared using low-pressure MOCVD have been examined. Trimethyl-aluminum (TMAI) and hydrogenchloride (HCl) were used as donor dopant sources. With Al doping, ZnS films, with resistivities as low as about 1  $\Omega\text{cm}$ , can be grown. In the photoluminescence of Al-doped ZnS, a near-band-edge emission and an SA emission are observed. A correlation between the resistivity and the SA emission intensity was found through which the resistivity decreases with an increase in the SA emission intensity. With Cl doping, films with resistivity as low as 0.2  $\Omega\text{cm}$  can be grown. It was found, however, that when the HCl flow rate was relatively high, the crystallinity tended to be poor, because of the reaction between HCl and the Zn-source material. (Author abstract) 20 refs.

Yamaga, S. (Chiba Univ, Chiba, Jpn); Yoshikawa, A.; Kasai, H. *J Cryst Growth* v 86 n 1-4 Jan 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 252-256.

**095531 DEPENDENCE ON GROWTH TEMPERATURE OF THE PHOTOLUMINESCENCE PROPERTIES OF NITROGEN-DOPED ZnSe GROWN BY MOCVD.** Growth of nitrogen-doped ZnSe films by low pressure MOCVD using dimethylzinc and hydrogen selenide as reactants has been carried out, and the dependence of low-temperature photoluminescence properties of nitrogen-doped films on growth temperature has been examined. It is shown that the nitrogen atoms act as shallow acceptors in ZnSe, with an activation energy of about 100-110 meV. However, some deep centers related to the nitrogen impurity are also introduced into highly nitrogen-doped ZnSe films, and the resistivity of nitrogen-doped ZnSe films remains high. (Author abstract) 27 refs.

Yoshikawa, A. (Chiba Univ, Chiba, Jpn); Muto, S.; Yamaga, S.; Kasai, H. *J Cryst Growth* v 86 n 1-4 Jan 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 279-284.

**095532 SUPERIORITY OF GROUP VII ELEMENTS OVER GROUP III ELEMENTS AS DONOR**

**DOPANTS IN MOCVD ZnSe.** Comparison of group III and group VII elements as donor species in ZnSe MOCVD growth has been studied from the viewpoint of their electrical properties, luminescence qualities and their controllabilities. Low resistivity high quality blue emitting ZnSe has been grown by doping a group VII donor chlorine, in atmospheric MOCVD. The superiority of group VII elements over group III elements with regard to carrier concentration controllability and carrier producing efficiency has been predicted. (Author abstract) 11 refs.

Kamata, Atsushi (Toshiba Corp, Kawasaki, Jpn); Uemoto, Tsutomu; Okajima, Masaki; Hirahara, Keijiro; Kawachi, Masaru; Beppu, Tatsuro. *J Cryst Growth* v 86 n 1-4 Jan 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 285-289.

**095533 STABILITY AND INTERDIFFUSION AT MOCVD GROWN ZnSe/GaAs INTERFACES.** ZnSe-/GaAs interface stability and its relation with the misfit-induced film degradation which occurs above a critical thickness of the ZnSe epilayer have been studied using Rutherford backscattering (RBS). The minimum backscattering yield  $X_{\text{min}}$  along the  $\langle 110 \rangle$  channeling direction increased from 6% to 12% with the increase of the ZnSe film thickness from 1800 to 3600 Angstrom, which may indicate an increase in the density of misfit dislocations above the critical thickness. Diffusion effects at the ZnSe/GaAs interface were observed for the thicker ZnSe film samples after thermal annealing at 600°C for 5 h as evidenced by the variations of the RBS random spectra. A marked contrast was observed in the lattice matched ZnSe/GaAs system, i.e., the interface was extremely stable even after thermal annealing. This indicates the importance of the lattice matching for the thermal stability of the heterointerface. (Author abstract) 6 refs.

## Composition Effects

**095534 COMPOSITION FAULTS IN  $\text{Zn}_{1-x}\text{In}_x\text{S}_{3-x}$  CRYSTALS.** Five members of the family  $\text{Zn}_{1-x}\text{In}_x\text{S}_{3-x}$  are studied by means of electron microscopy. It is found that all the compounds present hexagonal structures, with the same a-lattice parameter. The c-lattice constant depends on the stoichiometry, following a certain formula. In all the examined materials, composition faults are found, mainly as isolated faults and with an m-value smaller than the bulk material. Several polytypic forms, corresponding to the same composition, also exist. ZnS-rich crystals present no superstructure, most probably because of a random distribution of the cations in their sublattice. (Author abstract) 7 refs.

## Computation

**095535 COMMENT ON THE PIEZOPOLARON BOUND STATES IN SEMICONDUCTORS.** Following the perturbation theory of Bajaj et al. the ground state energy of a bound piezopolaron is computed for ZnS, ZnSe, ZnTe and CdTe. Extending this theory to the excited states, the L.A. phonon contributions to the Lamb-shifts in these piezoelectric semiconductors are obtained. It is found that these contributions are smaller by seven to eight orders when compared to the L.O. phonon contributions. (Author abstract) 14 refs.

## Crystal Lattices

**095536 LATTICE IMAGES OF ZnSe CRYSTALS.** Using a 300 kV transmission electron microscope, lattice images of ZnSe projected on the (110) plane have been obtained. A detailed comparison between experimental and simulated images is made. The traditional simulation obtained by the superposition of free-atom potentials does not provide a fit to the elongation of close spots corresponding to adjacent columns of zinc and selenium atoms. It is also found that the difference in spot intensities for a through-focus series is not completely reproduced from such calculations. These deviations from experiment can be remedied by taking account of screening by valence-charge electrons. (Author abstract) 11 refs.

Watanabe, K. (Tokyo Metropolitan Technical Coll, Tokyo, Jpn); Hiratsuka, K.; Kikuchi, Y.; Yamaguchi, H. *Phil Mag Lett* v 56 n 2 Aug 1987 p 51-55.

**095537 EFFECT OF SCREENING IMAGES ON THE LATTICE OF ZnSe AND GaAs.** The crystal potentials of ZnSe and GaAs have been constructed by considering the reconstruction of valence charge electrons due to the crystallization. These potentials differ significantly from those obtained by the traditional method, consisting of the superposition of neutral atoms, in the low-order crystal potential components such as 111, 200, 220 and 311, especially in ZnSe. As a result, the distinctions in the image between the constituent atoms are more apparent in our results than in the traditional results. It is concluded that the lattice image calculation of these compounds needs to use the crystal potential which takes account of the accurate valence state and even thin crystals. (Author abstract) 16 refs.

## Defects

**095538 DEFECTS AND STRESSES IN ZnSe FILMS PRODUCED FROM ELEMENTOORGANIC COMPOUNDS (MOCVD) ON (100) GaAs SUBSTRATES.** The structural perfection and elastic state of a ZnSe/GaAs structure are investigated. The ZnSe films, which have a larger lattice parameter than the GaAs, are in an elongated state. The causes of the widening of the diffraction peaks of the film and the substrate are established and an explanation of the formation of a negative curvature radius of the structure is advanced. (Author abstract) 9 refs.

Kuznetsov, P.I.; Martovitskii, V.P.; Pechenov, A.N.; Skorbut, S.D.; Talenskii, O.N. *Sov Phys Lebedev Inst Rep* n 3 1987 p 1-6.

**095539 THERMODYNAMICAL CONSIDERATION OF DEFECT CONCENTRATIONS IN ZnSe.** The growth conditions of n and p type ZnSe crystals are clarified from thermodynamical analysis of the defect and carrier concentrations as a function of growth temperature and Zn vapor pressure. It is found that the hole concentration at 300°C is by  $10^{-4}$  -  $10^{-6}$  lower than a doped acceptor and that highly doping of an acceptor under a saturated Se pressure is necessary to get p type low resistivity crystals. On the other hand, n type crystals are easily obtained by doping a donor under saturated Zn pressure. (Author abstract) 8 refs. In Japanese.

Ido, Toshiyuki; Matsushita, Yuji. *Chubu Daigaku Kogakubu Kiyo* v 23 Oct 1987 p 33-36.

## Density

**095540 EFFECT OF ADDITIVES ON THE HOT PRESSING OF ZINC SULPHIDE.** Zinc sulphide is a promising chalcogenide semiconductor for electro-optic applications. The material is currently developed in the form of powder, thin film and single crystals. Ceramics having a high density with controlled dopant content is the fundamental requirement for application of the material in this field. This letter reports the preparation of high-density zinc sulphide ceramics containing various

additives by hot pressing. The result suggests achievement of nearly full density at 800°C at 40 MPa for undoped material. The larger grains in specimens doped with  $\text{Li}_2\text{S}$  and  $\text{Bi}_2\text{S}_3$  show that these dopants enhanced grain growth. 6 refs.

## Doping See Also VARISTORS—Stability.

**095541 LITHIUM AND PHOSPHORUS IMPURITIES IN ZnTe.** ZnTe crystals doped with Li or P in the range  $10^{16}$ - $10^{19} \text{ cm}^{-3}$  were characterized using electrical and luminescence measurements. The hydrogenic behavior of the acceptor centers was investigated using Hall measurements in the temperature range  $30 \leq T \leq 300 \text{ K}$ . The ionization energies at maximum dilution were found to be 0.048 eV and 0.042 eV for Li and P acceptors respectively. The effect of an annealing atmosphere (Zn or Te) on impurity concentration was studied. The results were found to be consistent with the segregation-diffusion model which invokes a three-phase equilibrium (Te precipitates)-(ZnTe matrix)-(vapor). In the ZnTe matrix, Li and P act as amphoteric impurities. The acceptors and donors are attributed to the substitutional ( $\text{Li}_{\text{Zn}}$ ,  $\text{P}_{\text{Te}}$ ) and the interstitial ( $\text{Li}_i$ ,  $\text{P}_i$ ) defects respectively. These defects initiate luminescence transitions in the near-band-edge region at 4 K. For nominally pure crystals, the excitonic nature of the principal band edge (PBE) line (due to residual Li acceptors) was principal band edge (PBE) line (due to residual Li acceptors) was confirmed through intensity versus temperature measurements. In Li- and P-doped crystals, further evidence was obtained for the assignment of the PBE line to a donor-to-valence-band transition. (Edited author abstract) 32 refs.

**095542 INDIUM-DOPED ZINC OXIDE FILMS PREPARED BY d.c. MAGNETRON SPUTTERING.** Transparent and conductive films of indium-doped zinc oxide have been prepared by reactive sputtering of Zn-In alloy targets with a conventional d.c. magnetron technique in controlled Ar +  $\text{O}_2$  gas mixtures. The films were deposited onto glass substrates at a constant discharge current of 50 mA. Indium-doped films were polycrystalline with small crystal grains (5-15 nm) exhibiting low Hall mobility of  $1.4 \times 10^{-4} \text{ m}^2 \text{Vs}^{-1}$ , high carrier concentration of  $1.3 \times 10^{20} \text{ m}^{-3}$  and optical transmittance of 70-80% in the wavelength range from 400 to 800 nm. A correlation between the electrical, optical and structural properties of these films was also investigated. (Author abstract)

Czernastek, H. (Pedagogical Univ, Cracow, Pol); Brudnik, A.; Jachimowski, M. *Solid State Commun* v 65 n 9 Mar 1988 p 1025-1029.

**095543 EFFECT OF COPPER IMPURITY ON THE EDGE EMISSION OF ZnTe CRYSTALS.** The results are given of studies on the edge emission of undoped and copper-doped ZnTe crystals in the temperature range 4.2-300°K. The copper impurity has been found to increase the intensity of the principal edge emission band substantially. Analysis of the structure of this emission band indicated that a temperature below 160°K the main role is played by the emission from excitons that are most probably bound in  $\text{Cu}_{\text{Zn}}$  and  $\text{Li}_{\text{Zn}}$  centers while at higher temperatures it is played by emission during the transition of free electrons to these centers. An appreciable role is played over the entire range of temperatures by emission from free electrons with an energy of 13 MeV. The luminescence quenching energy below 160 K has a value of 7 MeV (the binding energy of a bound exciton) and at higher temperatures it is 78 MeV. (Author abstract) 14 refs.

**095544 GALLIUM-DOPING EFFECTS ON THE MOLECULAR BEAM EPITAXIAL ZnS ON GaAs.** Twin-free ZnS:Ga epilayers were grown on (100)GaAs by MBE. The epilayers showed a smooth surface morphology. The PL spectrum exhibited a blue emission at 425 nm and a broad emission at 640 nm. The former was due to incorporated gallium and the latter may be a defect-related emission. When a post-annealing at 500°C for 30 min was carried out on the ZnS:Ga epilayers, the surface of the layer was slightly degraded due to a difference in the lattice constants of ZnS and GaAs. The intensity of the blue emission at 425 nm was increased about 50 times and the emission at 640 nm disappeared. 21 refs.

**095545 VERTICAL ZONE GROWTH AND CHARACTERIZATION OF UNDOPED AND Na, P AND Mn DOPED ZnSe.** We report the results of vertical zone growth of undoped and doped ZnSe of 50g charge sizes. Dopants studied were Na, P and Mn in the concentration range  $10^{18}$ - $10^{20} \text{ ions/cm}^3$ . The objective of the work was to study the influence of growth conditions and doping on the occurrence of twinning and to obtain material suitable for fabrication into (100) substrates. Sliced and polished wafers were studied by X-ray, optical and RHEED techniques. In undoped samples, clusters of twins occasionally interspersed with small twin free regions were commonly seen. Codoping with Na and P, resulted in a small increase in the quantity of twin free areas and a darkening of the ingots. Best results were achieved with Mn doping where twin free volumes up to  $3.5 \text{ cm}^3$  were obtained and which yielded (100) substrates for MBE. Not all Mn doped growth runs have led to twin free ZnSe crystals and the role of Mn is currently being investigated. (Author abstract) 9 refs.

**095546 NITROGEN AND PHOSPHORUS DOPING IN ZnS LAYERS GROWN BY VAPOR PHASE EPITAXY ON GaAs SUBSTRATES.** Electrical and photoluminescence (PL) properties have been examined for N-doped and P-doped ZnS layers grown by vapor phase epitaxy on GaAs substrates at about 700°C. Nitrogen doping was done during growth by adding ammonia in the hydrogen flow of an open tube growth system using a ZnS powder source. Phosphorus doping was done by thermal diffusion after growth in a sealed quartz ampoule kept at 500°C. Compared to undoped samples, notable changes of PL spectra at 77 K include the appearance of a new UV emission at 390 nm and the disappearance of the Cu-related emissions but only for N-doped samples, not for P-doped samples. Concerning the trap levels measured by transient thermoluminescence (TTL) method, no difference was found between doped and undoped samples, except their concentrations. Discussions on these results are given in terms of substitutional nitrogen forming compensating acceptors and associated centers with Cu impurities. (Edited author abstract) 11 refs.

**095547 OPTICALLY DETECTED MAGNETIC RESONANCE STUDY OF STRONGLY COUPLED SHALLOW DONOR-DEEP GOLD CENTRE PAIRS IN ZnSe.** We describe ODMR experiments in which the 575 nm emission from gold-doped ZnSe is shown to consist of two contributions. The first contribution is due to recombination in which an electron from a shallow

donor is transferred to a complex which we have previously denoted Au-3 and which is believed to consist of substitutional divalent gold associated with a perturbing ion X. The impurity X is required to be positive with respect to the lattice, and interstitial gold  $\text{Au}^{+1}$  is a likely candidate. The second contribution to the 575 nm band involves a donor electron which is strongly coupled to the  $\text{Au}^{2+}\text{Zn}$  ion of the Au-3 centre by the spin exchange interaction, and we suggest that this part of the emission is due to a charge transfer or excitonic recombination process within the Au-3 complex itself. The isotropic component of the exchange splitting is measured directly to be of magnitude  $1.13 \text{ cm}^{-1}$  (0.140 meV). (Author abstract) 12 refs.

## Electric Conductivity

**095548 CONDUCTION MECHANISM IN ZINC TELLURIDE FILMS.** Electrical conductivity of vacuum evaporated ZnTe films of different thicknesses (2000 Angstrom to 5000 Angstrom) has been investigated as a function of electrical field at different temperatures (77K and 307-353K). Observed non-ohmic conduction has been explained on the basis of modified Poole Frankel effect. The observed thermal activation energy (0.3-0.5eV) of electrical conduction is in agreement with the results of other workers. (Author abstract) 26 refs.

**095549 SOME STUDIES ON ZINC PHOSPHIDE FILMS GROWN BY HOT WALL EPITAXY.** Zinc phosphide ( $\text{Zn}_3\text{P}_2$ ) films were grown by the hot wall epitaxy technique on mica substrates in the temperature range 170 to 240°C. The surface morphology indicates that the grain size increases with the increase of substrate temperature corresponding to an activation energy of 0.32 eV. An analysis of the optical absorption spectrum indicates two direct transitions at 1.34 and 1.45 eV. The electrical conductivity varies from  $2 \times 10^{-5} (\Omega\text{cm})^{-1}$  in the temperature range 163 to 300 K. Minority carrier lifetime  $\tau = 1.23 \text{ ms}$  was measured using the photoconductivity technique. (Author abstract) 12 refs.

**095550 EFFECT OF VACUUM HEAT TREATMENT OF THE ELECTRIC CONDUCTIVITY OF ZINC OXIDE.** It is established that the effective bulk conductivity of powdered zinc oxide is determined by chemisorption effects on the surface of the oxide particles. An analysis of thermovacuum electric conductivity curves, together with dielectric measurements, made it possible to estimate the energy distance from the Fermi level to the level of occurrence of an adsorption-type trap, i.e. the energy of the transition from a charged form of chemisorption to a neutral form. It is shown that the main difference between the zinc oxide samples studied lies in the different locations of the Fermi level relative to the bottom of the conduction band, i.e., in different degrees of deviation from stoichiometry. Zinc oxide with a greater degree of nonstoichiometry is less suitable for the fabrication of nonlinear resistors. In Russian. 8 refs.

**095552 EFFECT OF VACUUM ANNEALING ON THE ELECTRICAL PROPERTIES OF  $\text{Zn}_3\text{P}_2$  THIN FILMS.**  $\text{Zn}_3\text{P}_2$  is one of the most promising alternatives for photovoltaic applications, and also for laser applications. Some results on the effect of post-deposition annealing on the electrical properties of  $\text{Zn}_3\text{P}_2$  films are presented. The dc conductivity measurements were made in the temperature range 100 to 300 K. The low temperature data have been analyzed on the basis of Mott's variable range hopping conduction process and the high-temperature data have been examined for the thermionic emission of the carriers over the grain boundaries. 17 refs.

Murali, K.R. (Indian Inst of Technology, Madras, India); Gopalam, B.S.V. *J Mater Sci Lett* v 7 n 2 Feb 1988 p 125-129.

**095553 INFLUENCE OF INTERFACE STATES ON THE ELECTRICAL PROPERTIES OF  $\text{Mg-Zn}_3\text{P}_2$  JUNCTIONS.** Zinc phosphide ( $\text{Zn}_3\text{P}_2$ ) has become a promising semiconductor for application in photovoltaic solar energy conversion. It has an energy gap equal to 1.5 eV close to the optimum value for photovoltaic solar energy conversion at room temperature. The value of the minority carrier diffusion length suggests a reasonable high energy conversion efficiency. This has led to an investigation of metal-Schottky barriers on  $\text{Zn}_3\text{P}_2$ , particularly  $\text{Mg-Zn}_3\text{P}_2$  junctions. To explain the bias dependence of the ideality factor the authors consider a simple model with one band of interface states on the  $\text{Zn}_3\text{P}_2$  surface. 12 refs.

**095554 TEMPERATURE AND COMPOSITION DEPENDENCES ON THE ELECTRICAL PROPERTIES OF As-GROWN  $\text{ZnHgTe}$  CRYSTALS GROWN BY THE TRAVELLING HEATER METHOD.** Temperature dependence on the electrical properties of unintentionally-doped  $\text{ZnHg}_{1-x}\text{Te}$  bulk crystals, grown by the traveling heater method with a Te solvent, has been investigated by means of the Hall measurements at temperatures in the range 77 to 300 K. The crystals grown from  $x=0.02$  to 0.8 at about 700°C exhibited typically n-type conduction at 300 K. In particular, the electron Hall mobility of  $x=0.2$  was about  $10^4 \text{ cm}^2/(\text{V}\cdot\text{s})$  at about 150 K, and from its temperature dependence a donor level was located at about 12 meV below the conduction band. The electron mobility at 300 K decreased remarkably due to alloy scattering with increasing composition  $x$ . We observed anomalous behavior in the temperature dependence of the hole mobility above  $x=0.33$ ; a maximum value was reached at about  $4 \times 10^3 \text{ cm}^2/(\text{V}\cdot\text{s})$  at 77 K. (Author abstract). 8 Refs.

man, A.W.; Russell, G.J.; Woods, J. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 667-672.

## Electronic Properties

**095556 ELECTRONIC PROPERTIES OF CERTAIN CHROMIUM SPINELS.** Some electronic properties of the following spinel series:  $\text{Zn}_{1-x}\text{Cr}_x\text{Cr}_2\text{Se}_4$ ,  $\text{Zn}_{1-x}\text{Ga}_{2x/3}\text{Cr}_2\text{Se}_4$  and  $\text{Co}_{0.55}\text{Cu}_{0.45}\text{Cr}_2\text{S}_4-y\text{Se}_y$  are presented. Using Slater's ideas on non-integer occupation numbers, the numbers of 3d holes (as the carriers of magnetism in these spinels) per Cr atom with spins up and down have been obtained. From the condition of self-consistency for the magnetic moment the number of occupied states at the Fermi level with given spin projection and the Pauli spin paramagnetic susceptibility have been calculated and compared with other terms of the total high field susceptibility. According to the Stoner-Edwards-Wohlfarth theory a set of important exchange and band parameters of these compounds was calculated for the first time. (Author abstract) 22 refs.

Juszczak, S. (Silesian Univ, Katowice, Pol). *J Magn Magn Mater* v 73 n 1 May 1988 p 18-26.

**095557 SUPEREXCHANGE IN HELICAL  $\text{Zn}_{1-x}\text{Ga}_{2x/3}\text{Cr}_2\text{Se}_4$ .** The exchange interactions in insulating, helical spinels have been explained on the basis of the Anderson-Kanamori theory of superexchange. The value of the exchange constants  $J_{BB}$  in the first three spheres of coordinations between the  $\text{Cr}^{n+}$  ions via  $\text{Se}^{2-}$  ligands have been estimated after taking into account the experimental data of the saturation field, the paramagnetic Curie-Weiss temperature and the assumption that the spin spiral angle increases linearly with increasing of Ga concentration. From the observed values of the exchange constants the transfer and direct integrals have been obtained which on further analysis yield the values of the covalency parameters. These parameters are found to be consistent with the chemical theory of covalency. (Author abstract) 18 refs.

Juszczak, S. (Silesian Univ, Katowice, Pol). *J Magn Magn Mater* v 73 n 1 May 1988 p 27-32.

**095558 STUDY OF s-d EXCHANGE INTERACTION IN  $\text{ZnFeSe}$  SEMIMAGNETIC SEMICONDUCTOR.** The magnetorefractivity and magnetic susceptibility was measured in  $\text{Zn}_{1-x}\text{Fe}_x\text{Se}$  ( $x < 0.07$ ). Large spin splitting was observed due to exchange interaction between band electrons and  $\text{Fe}^{2+}$  localized electrons. The exchange integrals are estimated for the first time for this iron-type material:  $\text{No}\alpha = 0.22\text{eV}$  and  $\text{No}\beta = -1.57\text{eV}$ . (Author abstract) 13 refs.

Twardowski, A. (Warsaw Univ, Warsaw, Pol); Glod, P.; de Jonge, W.J.M.; Demianiuk, M. *Solid State Commun* v 64 n 1 Oct 1987 p 63-67.

**095559 ELECTRONIC STRUCTURE OF CATIONIC CORE EXCITONS IN II-VI SEMICONDUCTORS.** The electronic structure of cationic core excitons in ZnS, ZnSe, ZnTe, and CdTe was analyzed by means of self-consistent-field multiple scattering  $X\alpha$  molecular cluster calculations. The exciton level introduced in the gap by the core hole is found to be weakly localized with a charge distribution similar to that of an isocoric single donor level. Core exciton binding and formation energies and also core ionization energies were calculated. The binding energies of the core excitons in ZnS are found to be almost independent of the depth of the core level involved. This behavior seems to be a general property of core excitons in semiconductors. Trends for core exciton binding energies, core level shifts and charge distributions are analyzed in the  $\text{ZnX}$  ( $X=\text{S}, \text{Se}, \text{Te}$ ) series and also in CdTe. (Author abstract). 19 Refs.

**095560 COMMENTS ON THE INTERPRETATION OF THERMALLY STIMULATED LUMINESCENCE AND CONDUCTIVITY IN CONDUCTIVE ZnSe CRYSTALS.** Recently Oczkowski presented new results of calculations of the shape and the position of the TL and the thermally stimulated conductivity (TSC) curves applying the modified kinetic model with metastable state of donor-acceptor pairs (MDA) and shallow donor. It is well-known that the characteristic values of the capture cross-sections of the recombination center for the free electron ( $S_n$ ) and hole are helpful for the determination of the nature of this center. This note presents a simple estimation of the  $S_n$  value for the center (unidentified H-center, possibly MDA, or deep hole trap, or other center) which keeps the captured hole for a long time after removing the optical excitation from the conductive n-type ZnSe crystal at 77 K. 13 Refs.

**095562 PHOTOLUMINESCENCE OF EXCITONS BOUND AT Te ISOELECTRONIC TRAPS IN ZnSe.**  $ZnSe_{1-x}Te_x$  belongs to the interesting class of semiconductor alloys in which Te acts both as an isoelectronic trap and as a constituent of the alloy. We have grown ZnSe single crystals having various concentrations of Te atoms from a mixture of Te and Se solutions. We observe an emission band having phonon structure and peaking at 2.67 eV in slightly Te-doped specimens ( $x < 0.008$ ), and a broad band at 2.48 eV in rather heavily Te-doped specimens ( $x \geq 0.046$ ). These two bands can be attributed respectively to recombination of excitons bound at  $Te_1$  atoms and  $Te_n$  ( $n \geq 2$ ) clusters. The results are interpreted in terms of intermediate electron-phonon coupling, and relevant optical processes are also discussed. (Author abstract) 14 refs.

Yao, T. (Electrotechnical Lab, Sakura-mura, Jpn); Kato, M.; Davies, J.J.; Tanino, H. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 552-557.

**095563 ALLOY-TRAPPED EXCITONS IN A NEW II-VI SEMICONDUCTOR SOLID SOLUTION  $Hg_{1-x}Zn_xTe$ .** Luminescence and reflectivity experiments were performed on Zn-rich  $Hg_{1-x}Zn_xTe$  crystals grown by THM. For compositions  $x > 0.90$ , the low temperature luminescence spectra are dominated by a broad line  $I_{L1}$  located a few meV below the free exciton ground state deduced from reflectivity. Selective excitation of luminescence within the  $I_{L1}$  band on an  $x = 0.94$  sample shows a narrowing line effect in the LO phonon luminescence replica. The behaviour of this line as a function of excitation energy and temperature indicates that it is due to radiative recombination of excitons localized in the potential wells associated with composition fluctuations. On samples richer in mercury ( $x < 0.90$ ) the luminescence spectra become dominated by a deeper band  $I_{L2}$  we attribute to excitons trapped on non-identified defects. (Author abstract) 18 refs.

## Grain Boundaries

**095565 TRANSIENT RESPONSE OF ELECTRICALLY ACTIVE GRAIN BOUNDARIES IN POLYCRYSTALLINE SEMICONDUCTORS.** In many polycrystalline semiconductors, the current transport is controlled by potential barriers formed at the grain boundaries. We investigate the response of  $ZnO$  grain boundaries to high-voltage pulses with risetime of less than 1  $\mu s$ . The experimental results, in particular the voltage overshoot effect, cannot be explained by the dynamics of electrons (majority carriers) alone. A model which includes holes (generated by hot electrons in the depletion regions) yields an appreciable overshoot when the steady state is close to a current-voltage bistability. In this case, the approach to equilibrium is altered by the delayed response of the barriers to the presence of holes. Further implications of the model are also discussed. (Author abstract) 26 refs.

**095566 VAPOUR PHASE EPITAXY OF WIDE GAP II-VI COMPOUNDS.**  $ZnS$  and  $ZnSe$  epitaxial layers of high crystallographic perfection have been grown by open-tube chemical vapor transport in the temperature range from 650 to 700°C at gas flows lower than 20 l/h. Low-temperature epitaxial growth (450 to 600°C) has been realized with halogen containing systems. VPE methods have been successfully applied to grow low resistivity  $ZnSe$  probes on GaAs (Zn excess, autodoping by Ga). Photoluminescence spectra show more gap-near emission than deep level luminescence. 28 refs.

Hartmann, H. (Akad der Wissenschaften der DDR, Berlin, East Ger); Mach, R.; Testova, N. *J Cryst Growth* v 84 n 2 Aug 1987 p 199-206.

**095567 THERMODYNAMICAL ANALYSES AND LUMINESCENCE PROPERTIES OF VAPOR-GROWN  $ZnS_{1-x}Se_x$ .** Vapor phase transport analyses are presented regarding the epitaxial growth of  $ZnS_{1-x}Se_x$  on GaP. It has been predicted from a thermodynamical calculation and experimentally confirmed that the solid composition  $x$  can be controlled over a wide range by varying the source and/or the substrate temperature. The photoluminescence of epitaxial layers of  $ZnS_{1-x}Se_x$  ( $0.44 \leq x \leq 0.92$ ) grown on GaP exhibits a strong edge emission at room temperature, showing that the epitaxial layers are of high quality. (Author abstract) 10 refs.

Goto, Hideo (Nagoya Univ, Nagoya, Jpn); Zhou, Jun; Sawaki, Nobuhiko; Akasaki, Isamu. *Jpn J Appl Phys Part I* v 26 n 8 Aug 1987 p 1300-1304.

**095568 HIGH-QUALITY  $ZnSe$  FILM GROWTH BY 0.1-ATM MOVPE UNDER THE DIETHYLZINC DIFFUSION-LIMITED CONDITION.** The effects of the growth conditions on the growth rate, crystallographic and luminescence properties were investigated for  $ZnSe$  film growth by metalorganic vapor phase epitaxy at 0.1 atm using diethylzinc and  $H_2Se$ . It was shown that high-quality epitaxial layers can be grown under the diethylzinc diffusion-limited condition over temperatures ranging from 250 to 500°C. These layers exhibit dominant

blue photoluminescence at 77 K. However, the optimum growth temperature for  $ZnSe$  layers having a smooth surface and high crystallographic properties is restricted to within the region between 300 and 400°C. (Author abstract) 17 refs.

**095569 ELECTRICAL AND LUMINESCENT PROPERTIES OF In-DOPED  $ZnSe$  GROWN BY LOW-PRESSURE VAPOR-PHASE EPITAXY.** In-doped  $ZnSe$  layers have been grown for the first time by low-pressure vapor-phase epitaxy using metallic Zn, Se and In as source materials on GaAs(100) substrates. The carrier concentration increases significantly with increasing In cell temperature, and is controlled in the range of  $10^{16}$ - $10^{18}$   $cm^{-3}$ . The near-band-gap emission also increases with In cell temperature. The highest carrier concentration achieved is  $1.3 \times 10^{18}$   $cm^{-3}$ , and even the most highly doped sample shows a photoluminescence spectrum dominated by the near-band-gap emission. (Author abstract) 10 refs.

**095570 LATTICE-MISMATCH ENHANCED DIFFUSION AT A  $ZnSe/GaAs$  INTERFACE - INCREASE OF THERMAL STABILITY IN A LATTICE-MATCHING SYSTEM.**  $ZnSe/GaAs$  interface diffusion, especially at an elevated temperature, was investigated. For  $ZnSe$  films of which stoichiometry was not completely maintained at the interface, the enhancement of Zn diffusion into GaAs was observed with an increase of film thickness. With preheating of GaAs substrates prior to growth,  $ZnSe$  films are stably deposited on GaAs. However, for thick  $ZnSe$  films of 7200 Å, the original n- $ZnSe/n$ -GaAs interface turned out to be converted to p-type at the interface after thermal annealing at 650°C for three hours. These interface diffusions which depend on the film thickness are estimated to be related with the misfit-induced lattice relaxation caused above a critical thickness. This hypothesis was confirmed by the extreme thermal stability found in the lattice-matched  $ZnS_{0.96}Se_{0.04}/GaAs$  interface. (Author abstract) 12 refs.

**095571 EFFECTS OF IODINE-DOPING ON THE HETERO-EPITAXIAL GROWTH OF  $ZnS$  ON GaP SUBSTRATES.** Single-crystalline  $ZnS$  layers have been grown on GaP substrates using an open-tube hydrogen transport system. By the addition of iodine to the reactant agents, the growth rate of  $AnS$  on GaP (111)A decreased and that on GaP (111)B increased. These changes of the growth rates caused by the iodine-doping process were characterized as the opposite behavior compared with those for the indium-doping case. For the growth on the GaP (100) plane, the deposition region has largely shifted to lower temperatures, and higher growth rates, such as  $\mu m/h$ , were obtained at considerably lower temperatures, such as 580°C. From an X-ray diffraction analysis, it was found that a significant improvement in the crystallinity of the grown layers on (100) substrates was caused by the doping of iodine. An improvement in the surface morphology for these layers was also clearly observed. (Author abstract) 7 refs.

**095572 GROWTH AND CHARACTERIZATION OF ZINC PHOSPHIDE CRYSTALS.** Zinc phosphide crystals ( $Zn_3P_2$ ) having a large grain size were grown with

purified source materials, using a necked quartz ampoule in order to control the transport rate of the nutrients. The electrical characteristics of the sliced wafer were measured as a function of both of the position along the growth direction of the ingot and the phosphorus composition  $x$  in the  $\text{Zn}_{1-x}\text{P}_x$ . The carrier concentration was found to vary along the growth direction. The electrical resistivity decreased from  $10^3$  to  $10^2 \Omega \text{ cm}$  simultaneously with an increase in the phosphorus composition of the grown crystal. (Author abstract) 11 refs.

**095573 USE OF METHYLSELENOL FOR ORGANOMETALLIC VAPOR-PHASE EPITAXY OF ZnSe.** Heteroepitaxial films of ZnSe on GaAs substrates have been grown by atmospheric-pressure organometallic vapor-phase epitaxy using a new selenium source, methylselenol,  $\text{CH}_3\text{SeH}$  (MSeH). Gas-phase prereaction with a group-II source material was suppressed compared with hydride sources, e.g.,  $\text{H}_2\text{Se}$ . The practical growth temperature was 300-400°C, which was sufficiently lower than 500°C used in the growth with dialkyl compounds. The epilayers exhibited a fairly smooth surface morphology and good crystallographic properties. Higher quality epilayers can be expected with source repurification or synthesis via purer chemical processes. (Author abstract) 11 refs.

**095574 INTERFACE STRESS AT OMVPE-GROWN  $\text{ZnS}_x\text{Se}_{1-x}$ /GaAs:Cr HETEROSTRUCTURE.** The interface stress at OMVPE-grown  $\text{ZnS}_x\text{Se}_{1-x}$ /GaAs:Cr ( $x=0.03$  to approx. 0.14) heterostructures has been investigated the Cr-related photoluminescence line at 0.839 eV from GaAs:Cr substrates. From analysis of the shift of the related luminescence line, it has been found that the GaAs substrates at the heterointerface suffer compressive almost independent of the composition of  $\text{ZnS}_x\text{Se}_{1-x}$  epitaxial layers. Such compressive stress at the GaAs substrates be explained as being due to the difference between the thermal expansion coefficients of  $\text{ZnS}_x\text{Se}_{1-x}$  and GaAs; thermal stress introduced in cooling from the growth temperature (500°C) of  $\text{ZnS}_x\text{Se}_{1-x}$  on GaAs. (Author abstract) 18 refs.

**095575 VARIATION OF MISFIT STRAIN IN ZnSe HETEROEPITAXIAL LAYERS WITH TEMPERATURE, LAYER THICKNESS AND GROWTH TEMPERATURE.** The temperature variation of misfit strain in ZnSe layers grown on GaAs(100) substrates has been measured at 80 to approx. 600 K for layer thicknesses of 0.2 to approx. 4.0  $\mu\text{m}$  by X-ray diffraction. Layers as thin as 0.2  $\mu\text{m}$  grow coherently on the substrate and the coherency holds even for low temperatures. Strain-free layers at room temperature include those with two-dimensional expansive strain. Layers with two-dimensional compressive strain with  $\epsilon \approx +0.03$  percent at room temperature become strain free at 80 K. The X-ray analysis is consistent with low-temperature reflection spectra. (Edited author abstract) 21 Refs.

**095576 NOVEL ATMOSPHERIC PRESSURE TECHNIQUE FOR THE DEPOSITION OF ZNS BY ATOMIC LAYER EPITAXY USING DIMETHYLZINC.** We report on the results of a novel atomic layer epitaxy (ALE) deposition system which performs deposition at atmospheric pressure. Polycrystalline thin films of ZnS have been deposited using the gaseous sources dimethylzinc and hydrogen sulfide. Depositions were

carried out at substrate temperatures in the range 25 to 500°C. The results of several bulk and surface analytical techniques are presented which suggest that the films are stoichiometric and of high purity and crystal quality. The methodology of system operation is discussed as is the dependence of film quality upon process parameters. (Author abstract) 12 Refs.

Hunter, Adolph (McMaster Univ, Hamilton, Ont, Can); Kitai, Adrian H. *J Cryst Growth* v 91 n 1-2 Aug 1988 p 111-118.

**095577 ZnSe-ZnTe STRAINED-LAYER SUPERLATTICES: A NOVEL MATERIAL FOR THE FUTURE OPTOELECTRONIC DEVICES.** ZnSe-ZnTe strained-layer superlattices (SLSs) were grown by molecular beam epitaxy (MBE). The optical properties of the ZnSe-ZnTe SLS were evaluated by photoluminescence (PL). The PL peak position was shifted by tailoring the structure of the superlattice. The luminescence color in the visible changed from blue-green to red. In order to obtain both p- and n-type conduction in wide-bandgap II-VI compound semiconductors, we have prepared ZnSe-ZnTe superlattices with a modulation doping technique. When Sb was selectively doped in ZnTe layers, all the samples exhibited p-type conductivity with hole concentrations of  $(0.5-1.0) \times 10^{14} \text{ cm}^{-3}$ . On the other hand, Ga-doped SLSs were type with electron concentrations of  $(2-7) \times 10^{13} \text{ cm}^{-3}$ . Furthermore, the growth of ZnSe-ZnS SLSs was also demonstrated by metalorganic molecular beam epitaxy (MOMBE). Blue luminescence related to the quantized levels in the SLS was detected. (Author abstract) 14 refs.

**095578 MOLECULAR BEAM EPITAXIAL GROWTH AND CHARACTERIZATION OF ZnTe AND CdTe ON (001) GaAs.** Investigations of elemental diffusion in (001) and (111) oriented CdTe and ZnTe layers grown by molecular beam epitaxy on (001) GaAs substrates show high Ga diffusion along dislocations and defects generated at the substrate-epitaxial interface. The use of CdTe/ZnTe superlattice buffer layers and nucleation on near-atomically planar GaAs surfaces is shown to suppress Ga diffusion to background detection levels. (Author abstract) 9 refs.

Wagner, B.K. (Georgia Tech Research Inst, Atlanta, GA, USA); Oakes, J.D.; Summers, C.J. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 296-302.

**095579 MOLECULAR BEAM EPITAXIAL GROWTH AND STRUCTURAL CHARACTERIZATION OF ZnS ON (001) GaAs.** The effect of surface nucleation processes on the quality of ZnS layers grown on (001) GaAs substrates by molecular beam epitaxy is reported. Reflection high energy electron diffraction indicated that nucleation at high temperatures produced more planar surfaces than nucleation at low temperatures, but the crystalline quality as assessed by X-ray double crystal diffraction is relatively independent of nucleation temperature. A critical factor in layer quality was the initial roughness of the GaAs surfaces. (Author abstract) 21 refs.

**095580 MBE GROWTH OF HIGH QUALITY LATTICE-MATCHED  $\text{ZnS}_x\text{Se}_{1-x}$  ON GaAs SUBSTRATES.** We present the optimum growth conditions of lattice-matched  $\text{ZnS}_x\text{Se}_{1-x}$  ( $x$  approximately 0.055) by MBE on (100) GaAs substrates. Surface morphology, X-ray diffraction and photoluminescence were investi-

gated, and the optimum growth conditions were revealed as follows: The molecular beam intensity ratio of the group VI to II element is around 2.0 and the substrate temperature is 340°C. This molecular beam ratio means that the surface coverage fractions of the group II and group VI atoms are the same during growth. It is shown by comparing the photoluminescence spectra that the quality of the  $\text{ZnS}_x\text{Se}_{1-x}$  epilayers was higher than that of ZnSe. (Author abstract) 13 refs.

**095581 HOMO-EPITAXIAL GROWTH OF ZnSe BY MBE.** Homo-epitaxial growth of ZnSe on melt-grown ZnSe single crystals with (110) or {111} surfaces orientation has been performed to obtain strain-free layers. Epitaxial growth was successful only on  $(\bar{1}11)$  and (110) substrate surfaces, which were prepared by chemical etching using a chromic acid mixture or a mixture of ammonia and hydrogen peroxide solution. Photoluminescence spectra measured at 4 K showed the strong Y and S lines and a broad band on the low energy side. While the layers of ZnSe grown on GaAs substrates with smooth surfaces showed only strong and sharp excitonic lines, growth on the rough ZnSe surface introduced disorder in the epitaxial layer degrading the luminescence response. (Author abstract) 6 refs.

Ohishi, M. (Okayama Univ of Science, Okayama, Jpn); Ohmori, K.; Fujii, Y.; Saito, H.; Tiong, S. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 324-328.

**095582 MOLECULAR BEAM EPITAXIAL GROWTH OF NITROGEN-DOPED ZnSe WITH ION DOPING TECHNIQUE.** Nitrogen-doped ZnSe layers on GaAs substrates have been prepared by an ion doping with nitrogen during molecular beam epitaxial growth of ZnSe in an attempt to obtain p-type crystals. The preliminary work using a simple ion source without a mass separator indicated that a considerable contamination of donor species occurred, together with the doping of nitrogen acceptors. The low-temperature photoluminescence (PL) was dominated by a strong donor-acceptor pair (DAP) emission. The best result obtained was with an N-doped layer exhibiting a PL spectrum dominated by a strong acceptor-bound-exciton emission  $I_1$  whose peak intensity was 40 times greater than that of the DAP emission. The optimum condition for ion doping was investigated in terms of ion energy and ion current density. A temperature dependence of the PL spectrum was also reported. (Edited author abstract) 8 refs.

**095583 ZnSe AND ZnSe/Ge EPI-LAYERS GROWN ON (100) Si BY MOLECULAR BEAM EPITAXY.** ZnSe layers in the thickness range 2 to 3  $\mu\text{m}$  were grown on (100) Si substrates with intermediate Ge epi-layer buffers. Ge epi-layers (approximately 0.5  $\mu\text{m}$  thick) were grown by Knudsen evaporation of Ge from a FBN crucible at Si substrate temperatures around 330°C. The Ge layer growth-rate being typically 0.33  $\mu\text{m/h}$  ( $2 \times 2$ ) reconstructed Ge surfaces were observed during Ge deposition by RHEED, the RHEED patterns being indicative of extremely smooth Ge surfaces. ZnSe layer quality was assessed using photoluminescence, SEM and cross-sectional TEM analyses, with layer quality achieved using superlattice buffers and single Ge epi-layer buffers being compared to that obtained by growing ZnSe directly on (100) Si. Cross-sectional TEM analysis showed the

layers grown with a two-period superlattice buffer to contain a significantly reduced concentration of structural defects. (Edited author abstract) 5 refs.

Park, R.M. (3M Canada Inc, Downsview, Ont, Can); Mar, H.A.; Kleiman, J. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 335-341.

**095584 ZnSe HOMO-EPITAXIAL GROWTH BY MOLECULAR BEAM EPITAXY.** High-quality undoped ZnSe homo-epitaxial growth by molecular beam epitaxy was demonstrated. A chemical etchant  $\text{H}_2\text{O}_2$ ,  $\text{NH}_4\text{OH}$  and  $\text{H}_2\text{O}$ , combined with a new thermal cleaning process, has been found promising for obtaining good initial ZnSe substrate surfaces necessary for high-quality homo-epitaxial growth by molecular beam epitaxy. The photoluminescence (PL) result is compared to that of a hetero-epitaxial layer on GaAs (001) substrate. A free excitonic PL emission line has been distinctly observed on the homo-epitaxial ZnSe layer grown on (001) substrate. A dominant emission line  $I_2$  in the 4.2 K PL spectrum of the homo-epitaxial ZnSe layer has been ascribed to In donors introduced by the In solder used to adhere the substrate to the molybdenum holder. (Author abstract) 10 refs.

Menda, Kazunori (Sumitomo Metal Mining Co, Ohme, Jpn); Takayasu, Ichiro; Minato, Tetsuo; Kawashima, Mitsuo. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 342-347.

**095585 LUMINESCENCE PROPERTIES OF ZnS/GaAs GROWN BY GAS SOURCE MBE.** High purity cubic ZnS films were grown on GaAs(100) by the gas source MBE method using  $(\text{CH}_3)_2\text{Zn}$  and  $\text{H}_2\text{S}$  as source materials. Photoluminescence studies of these films by the excitation of an  $\text{N}_2$  or an Xe-Cl excimer laser have shown that the intensity of self-activated emission depends on the  $[\text{S}]/[\text{Zn}]$  ratio and the substrate temperature. No SA emission was observed for ZnS films grown at 400°C or more with an  $[\text{S}]/[\text{Zn}]$  ratio of 2.3. Band edge emission consists of four sharp lines. The one at the highest photon energy, 3.797 eV, can be assigned to the recombination of a free exciton. (Author abstract) 10 refs.

**095586 CRYSTAL GROWTH OF ZnO BY CHEMICAL TRANSPORT.** Crystal growth of ZnO has been carried out by chemical transport in a closed tube using ammonium halides ( $\text{NH}_4\text{X}$ ), Zn,  $\text{ZnCl}_2$ , etc. as transport agents. Prismatic crystals of ZnO up to 1.5 mm in diameter and 8 mm in length were grown when  $\text{NH}_4\text{Cl}$  was used. The transport rate depended nearly proportionally on the undercooling, but not markedly on the amount of  $\text{NH}_4\text{Cl}$  added. When Zn and  $\text{ZnCl}_2$  were used, prismatic crystals were grown as well. The crystals grown were colorless or light-brown colored, and showed blue-green or yellow-green photoluminescence under UV excitation. When  $\text{NH}_4\text{Br}$  or  $\text{NH}_4\text{I}$  was used, however, only few crystals were obtained. (Author abstract) 23 refs.

**095587 PHOTOLUMINESCENCE AND CYCLOTRON RESONANCE STUDIES ON HIGHLY PURIFIED ZnSe SINGLE CRYSTALS.** In order to prepare low resistivity p-type crystals with good reproducibility for practical use, the development of preparation procedures for high purity single crystals and also the research of their physical properties and of the impurity effect on them should be done. For this reason, we have prepared high purity ZnSe single crystals and evaluated the grown crystals by photoexcited cyclotron resonance and photo-

luminescence (PL) measurements. In the present paper, our recent results obtained on highly purified ZnSe single crystals are reviewed and some discussions are given. 38 refs.

**Impurities** See Also SOLIDS—Impurities.

**095589 TIGHT-BINDING DESCRIPTION OF ISOVALENT IMPURITY CLUSTERS. APPLICATIONS TO Te IMPURITIES IN II-VI COMPOUND SEMICONDUCTORS.** For centers of several Te substitutionals in nearest-neighbor anion position in the host crystals ZnS, ZnSe, CdS, and CdSe a tight-binding description is given. The matrix of the Hamiltonian in the  $sp^3$ -representation includes all interactions up to the second-nearest neighbors and is based upon a charge self-consistent parametrization. All Te centers suitable in a tetrahedrally coordinated five-atom cluster are considered. Using the Koster-Slater scattering theory the off-diagonal matrix elements of the impurity potential have to be included. Thereby the results of the calculation are in good agreement with experimental data for the energy levels of complex Te impurities in II-VI semiconductors. (Author abstract) 10 refs.

**095590 ALKALI ATOMS AS ACCEPTOR IMPURITIES IN ZnSe.** The electronic structure of Li, Na, and K substitutional impurities in ZnSe are calculated within the framework of the self-consistent-field multiple-scattering molecular cluster model. The Li and Na impurities induce an  $a_1$  resonance in the valence band and at  $t_2$  state in the band gap. According to our results, the Li and Na acceptor states originate from the  $t_2$  orbital in the gap. The degree of localization of the gap state increases with atomic number, as a result from core repulsion effects and from the orthogonality between the impurity states. We suggest that the latter mechanism could be applied to Li and Na acceptors in other II-VI compounds. (Author abstract) 15 refs.

**095591 DETECTION AND CONTROL OF IMPURITY INCORPORATION IN MBE-GROWN ZnSe.** Intentionally- and unintentionally-doped ZnSe films were grown on (100)-oriented GaAs substrates by molecular beam epitaxy. The incorporation of intentional and unintentional dopants in these films was investigated through the use of photoluminescence, selectively-excited photoluminescence, secondary ion mass spectrometry and Hall measurements. Gallium and chlorine were detected in the undoped epilayers and these impurities were found to be associated with the well-known  $I_x$  and  $I_{20}$  donor-bound excitonic emissions seen in the photoluminescence. Furthermore, it was found that extrinsic impurities

appeared to be responsible for the electrically active donors in the undoped films and these impurities originated from the Se source material. The results of our initial attempts at doping with sodium and phosphorus are also reported here. (Edited author abstract) 15 refs.

**Ion Implantation**

**095593 PERSISTENT PHOTOENHANCEMENT OF HYDROGEN-IMPLANTED QUANTIZED ACCUMULATION LAYERS ON ZnO SURFACES.** Strong hydrogen-implanted accumulation layers on ZnO surfaces, produced and maintained at 80 K, can be further enhanced by illumination with visible light. The attainable enhancement is surprisingly large, resulting in an enormous surface electron density of up to  $6 \times 10^{14} \text{ cm}^{-2}$ , and persists indefinitely after the light is switched off. The photoenhancement layer is practically identical in width (10-20 Å) and transport characteristics to the implanted layer upon which it is based. The photoenhancement effect is not fully understood. Various aspects of this effect are studied in an attempt to gain some insight into the processes involved. On the basis of the results presented we tentatively suggest that latent centers consisting of  $\text{H}_2^+$  species are introduced by the hydrogen implantation, in addition to the fully ionized proton donors responsible for the implanted accumulation layer. (Edited author abstract). 16 Refs.

**Magnetic Properties**

**095594 HIGH FIELD MAGNETIZATION STEP IN  $\text{Zn}_{1-x}\text{Mn}_x\text{Te}$ .** Low temperature and high field magnetization experiments ( $H \leq 19 \text{ T}$ ) were carried out in diluted  $\text{Zn}_{1-x}\text{Mn}_x\text{Te}$  alloys ( $x = 0.03$ ). At 1.3 K, the first magnetization step, corresponding to the level crossing for pairs of nearest-neighbors (NN) is observed around  $H \approx 15 \text{ T}$ . Magnetization data are analyzed including, within the molecular field approximation (MFA), interactions between Mn ions distributed in small clusters (singles, pairs, triangles) with more distant neighbors than NN. Both the saturation value observed at  $H \approx 10 \text{ T}$  and the magnitude of the step agree with a random Mn distribution. Theoretical fits of the magnetization step provide a determination of the NN exchange constant  $J/k = -9.25 \pm 0.3 \text{ K}$ . (Author Abstract) 15 refs.

**095595 MAGNETIC PROPERTIES OF  $\text{Zn}_{1-x}\text{Mn}_x\text{S}$ .** The low temperature ac susceptibility and specific heat of the diluted magnetic semiconductor  $\text{Zn}_{1-x}\text{Mn}_x\text{S}$  has been measured for Mn concentrations below  $x = 0.10$ . A paramagnetic to spin-glass transition has been observed for all concentrations. The concentration dependence of the

freezing temperature,  $T_F(x)$ , is compatible with a radial decay of the antiferromagnetic d-d interaction. The magnetic contribution to the specific heat can be described in the pair-approximation using  $J_{NN}/k_B = -16$  K for the nearest neighbor and  $J(R)/k_B = -10R^{-7.6}$  K for the long range part of the interaction. For these parameters also a fair agreement with reported high-field magnetization and high temperature susceptibility data can be obtained. (Edited author abstract) 15 refs.

**095596 AUGER QUENCHING OF LUMINESCENCE IN ZnSe: Mn.** The Auger coefficient for quenching of manganese luminescence by free carriers in ZnSe:Mn has been measured. Its value is  $5 \times 10^{-10} \text{ cm}^3 \text{ s}^{-1}$ . This value is similar to that found for ZnS:Mn and is anomalously large. A possible explanation involving energy band matching is discussed. (Author abstract) 15 refs.

**095597 OPTICAL BLEACHING OF THE F+ OPTICAL ABSORPTION BANDS IN ZnS CRYSTALS.** The optical bleaching of the 2.3 and 2.9 eV bands related to the F+ centers in the electron-irradiated and Zn-treated ZnS crystals are measured from 25 K to room temperature under illumination of light from 395 to 702 nm. It is found that the 2.9 eV band is bleached in exactly the same manner as the 2.3 eV band. These bands are confirmed to be due to the same defects. It is deduced that the 2.3 eV absorption band is due to the transition of electrons from the ground state to the lower excited state located (49±5) meV below the conduction band, while the 2.9 eV band is due to the transition to the higher excited state located in or closely below the conduction band. (Edited author abstract) 20 refs.

**095598 EDGE AND SELF-ACTIVATED HIGH BAND EMISSION OF ZnS<sub>1-x</sub>Se<sub>x</sub> SINGLE CRYSTAL EPITAXIAL LAYERS.** Intense edge and self-activated (SA) emissions have been observed in the ZnS<sub>1-x</sub>Se<sub>x</sub> ( $x > 0.41$ ) epitaxial layers grown on (100) GaP substrates. The edge emission shows a peak shift to the high-energy side with an increase in the ZnS molar fraction  $x$  and/or a decrease in the temperature. This emission is attributed to the donor (Al)-acceptor (Na) pair emission. The binding energies of the donor and acceptor were determined from thermal quenching curves. The SA band shows a peak shift to the low-energy side with a decrease in the temperature. Its peak energy increases with an increase of  $x$ , and is about 0.25 eV higher than that expected for the usual SA emission, showing that this band is due to the SA high band emission. (Author abstract) 31 refs.

**095599 TRANSIENT BEHAVIORS OF THE 2.5 eV EMISSION BAND IN Se-TREATED ZnSe CRYSTALS.** ZnSe has been widely studied because of its potential as an efficient blue light emitter. However, it is difficult to make conducting n-type and p-type ZnSe because of the compensation effects by residual impurities and/or intrinsic defects. This work was done to clarify the nature of intrinsic defects induced by heat treatments. The transient behavior of the 2.5 eV emission band were

measured from 5 to 135 ns and emission mechanisms are discussed. 19 refs.

**095600 INTRA-MANGANESE ABSORPTION AND LUMINESCENCE IN Zn<sub>1-x</sub>Mn<sub>x</sub>Se SEMI-MAGNETIC SEMICONDUCTOR.** Optical absorption and luminescence of Zn<sub>1-x</sub>Mn<sub>x</sub>Se ( $0 < x < 0.53$ ) is measured at T = 10, 77 and 300 K below fundamental absorption edge. Three absorption and one luminescence bands are observed and are attributed to the intra-ion transitions of Mn<sup>2+</sup> in 3d<sup>5</sup> configuration. Crystal field parameter Dq and Racah parameters B and C are derived as well as stabilization energy. (Author abstract) 21 refs.

**095601 2.5 eV EMISSION BAND IN THE Se-TREATED ZnSe CRYSTALS.** Zinc selenide crystals grown by sublimation methods were treated in Se and/or Zn vapor of 400 to 660°C. Photoluminescence spectra were measured from 16 to 200 K. A new emission band near 2.5 eV is induced by Se treatments. This band is enhanced by increasing the time of Se treatment and decreased by Zn treatment. No shift in the peak energy of this band was observed with increasing excitation intensity delay time, so the 2.5 eV band is not due to donor-acceptor pair recombination. It is proposed that this band is related to Se-excess defects. (Edited author abstract) 23 refs.

**095602 LOW TEMPERATURE PHOTOLUMINESCENCE IN Zn<sub>3</sub>P<sub>2</sub>.** Zinc phosphide, Zn<sub>3</sub>P<sub>2</sub>, has been studied to its promising photovoltaic properties. It has become one of the high-efficiency semiconductors used on solar energy conversion. This compound has a direct optical bandgap of approximately 1.5 eV at 300K, 1.645 eV at 80 K, and 1.685 eV at 5 K. In the present note measurements of photoluminescence in the 1.48 to 1.70 eV range are reported at liquid helium temperature. 12 Refs.

Misiewicz, J. (Technical Univ of Wroclaw, Wroclaw, Pol). *Phys Status Solidi A* v 107 n 1 May 1988 p K65-K68.

**095603 ELECTROLUMINESCENCE IN AG- OR CU-DOPED ZnSe MIS STRUCTURE.** ZnSe having a direct band gap of 2.71 eV at room temperature is one of the promising semiconducting materials for preparing visible light emitting electroluminescent devices. This was directed to studying the blue EL in a forward-biased undoped ZnSe MIS structure. It is found that the red band at 650 nm is obtained at RT, and the Cu-R and Cu-G bands at 630 nm and 530 nm, respectively, are obtained at liquid nitrogen temperature. This is the first time that the green EL band at 562.5 nm is obtained at RT. (Edited author abstract). 10 Refs. In Chinese.

**095604 JAHN-TELLER EFFECT AND OPTICAL PROPERTIES OF ZnSe:Fe<sup>2+</sup>.** Zeroth-order vibronic wave functions are built in the Born-Oppenheimer limit as symmetrized products of electronic functions and vibronic functions corresponding to up to N vibrational quanta. A linear Jahn-Teller Hamiltonian is then added to the spin-orbit and static crystal-field contributions which are taken as fixed parameters in accordance with their established properties. The diagonalization of the whole Hamiltonian predicts the energies and intensities of the absorbed lines which are then compared with the spectra. Good agreement with experiment is obtained when the energy of the coupling phonon  $\hbar\omega$  is 65 cm<sup>-1</sup> (good correspondence with the lattice dynamics of ZnSe) and the Jahn-Teller energy  $E_{JT}$  is 230 cm<sup>-1</sup> (in the same range of the reported values for ZnS:Fe<sup>2+</sup> and CdTe:Fe<sup>2+</sup>). It is

found that good stability is reached for N ≥ 8. The values of  $\hbar\omega$  and  $E_{JT}$  reported above correspond to the case N = 10. (Edited author abstract) 12 refs.

**095605 OPTICAL INVESTIGATION OF THE DILUTED MAGNETIC SEMICONDUCTOR Zn<sub>1-x</sub>Mn<sub>x</sub>Te.** Zn<sub>1-x</sub>Mn<sub>x</sub>Te alloys ( $0 \leq x \leq 0.72$ ) have been investigated by photocurrent spectroscopy, electroreflectance in the electrolyte configuration and under vacuum by absorption and reflectivity measurements. Electroreflectance enables one to accurately determine the fundamental gap as a function of the alloy composition. We find  $E_0(x) = (2.28 + 0.53x)$  eV, a linear law which is in good agreement with previously published results. In the case of thermally treated samples with x approximately 0.70 electroreflectance, photocurrent and absorption spectroscopy indicate that the fundamental transition may be totally different from what is expected depending on the part of the ingot from which the samples the originate ( $E_0 = 1.854$  eV instead of 2.65 eV). It is assumed on the basis of complementary investigations that the complete band structure of the anomalous samples is shifted towards lower energy values. (Author abstract) 22 refs.

Lemasson, P. (CNRS, Thiais, Fr); Nguyen Van Huong, C.; Benhida, A.; Lascaray, J.P.; Triboulet, R. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 564-569.

**095606 ELECTROCHEMICAL AND ELECTRO-OPTICAL PROPERTIES OF Hg<sub>1-x</sub>Zn<sub>x</sub>Te.** An experimental study of Hg<sub>1-x</sub>Zn<sub>x</sub>Te (ZMT) over the whole composition range is carried out, using an electrochemical technique, electrolyte electroreflectance (EER) and photocurrent spectroscopy. ZMT alloys exhibit good electrochemical stability in aqueous as well as in aprotic solution. Well-featured EER spectra are obtained. By analysis of EER lineshape and photocurrent spectra, interband transition energies  $E_0$  and  $E_1$  are determined. The results show that Hg rich ZMT alloys, grown by THM have a good chemical stability, low defect density and thus are very promising for infrared detector devices. (Author abstract) 18 refs.

## Oxidation

**095608 SURFACE OXIDATION OF ZnHgTe AND ITS INTERFACE REACTION WITH METALS.** Migration processes of the constituent atoms and the interface properties in p- and n-type ZnHgTe crystals subjected to thermal oxidation or to metal deposition have for the first time been investigated by means of X-ray photoelectron spectroscopy (XPS) and Auger electron spectroscopy (AES) measurements in combination with ion-depth profile technique. The significant evaporation of Hg and Zn migration during oxidation have been observed and both play an important role for the oxidation process. As in the case of oxidation of CdHgTe, ZnTeO<sub>3</sub>

resulting from ZnO and TeO<sub>2</sub> formation may be considered to be one of the major constituents on the oxide surfaces. We have found both out-diffusion of Te and in-diffusion of Au at room temperature in Au/ZnHgTe and Au/ZnTe. A tentative interdiffusion model is proposed. (Author abstract) 12 refs.

## Phase Transitions

**095609 THERMODYNAMIC ANALYSIS AND PHASE EQUILIBRIA CALCULATIONS FOR THE Zn-Te, Zn-Se AND Zn-S SYSTEMS.** The available thermodynamic and phase equilibria data for the binary systems Zn-Te, Zn-Se and Zn-S have been analyzed using an 'associated solution model' for the liquid phases and considering the ZnTe, ZnSe and ZnS phases as line compounds. The phase diagrams and thermodynamic properties calculated from the optimized phase parameters agree well with the experimental data. (Author abstract) 58 refs.

Sharma, Ramesh C. (Indian Inst of Technology, Kanpur, India); Chang, Y. Austin. *J Cryst Growth* v 88 n 2 Apr II 1988 p 193-204.

## Photoconductivity

**095610 ON THE PHOTOCONDUCTIVITY RELAXATION IN ZnIn<sub>2</sub>S<sub>4</sub>.** The relaxation process of photoconductivity in ZnIn<sub>2</sub>S<sub>4</sub> is investigated together with optical quenching and thermally stimulated current. Photocurrent decays are processed by four-gate technique of photoinduced current transient spectroscopy (PICTS). A non-exponential behavior of the decays, due to a non-linear multichannel recombination mechanism, leads to 'anomalous' PICTS spectra that in the temperature range 200 to 300 K allow to evidence a thermal emission from a center with a repulsive potential barrier. The photoconductivity relaxation in the 80 to 200 K range is attributed to two competitive recombination channels. Models for the relaxation through both radiative and non-radiative recombination channels are proposed on the basis of optical quenching effect. (Edited author abstract). 19 Refs.

## Physical Properties

**095611 PREPARATION AND CHARACTERIZATION OF SEVERAL II-IV-V<sub>2</sub> CHALCOPYRITE SINGLE CRYSTALS.** Single crystals of ZnSiP<sub>2</sub>, ZnGeP<sub>2</sub>, ZnGeP<sub>1.8</sub>As<sub>0.2</sub>, and ZnGeP<sub>1.6</sub>As<sub>0.4</sub> have been grown by several techniques and their electronic and optical properties were compared. For ZnSiP<sub>2</sub> there are marked absorption bands at 10 and 11.5 μm, and at 13 μm for ZnGeP<sub>2</sub>. Upon substitution of 10 mole% of arsenic for phosphorus, the latter band does not shift to higher wavelengths. Further substitution of arsenic for phosphorus in ZnGeP<sub>2</sub> showed a weak second band at 9.8 μm. (Author abstract) 16 refs.

**095613 RADIATIVE RECOMBINATION IN HIGHLY EXCITED ZnSe.** Photoluminescence spectra and lifetime measurements are obtained at 1.8 K on high purity zinc selenide single crystals for different excitation intensities. At high power densities, two new luminescent bands at 2800 meV and 2798.5 meV are observed. The spectral position of these emission bands, combined with their transient behavior, suggest that these peaks are due to the biexciton recombination line and to the biexciton-biexciton collision line. (Author abstract). 13 Refs.

## Pressure Effects

**095614 PRESSURE DEPENDENCE OF THE LOWEST DIRECT ABSORPTION EDGE OF ZnTe.** The dependence of the lowest direct absorption gap E<sub>0</sub> of ZnTe on hydrostatic pressure has been measured at room temperature with a diamond anvil cell for pressures up to the second phase transition (11.9 ± 0.3 GPa). The energy gap E<sub>0</sub> (eV) = 2.27 + 10.4 · 10<sup>-2</sup> · P - 28 · 10<sup>-4</sup> · P<sup>2</sup> (P in GPa) exhibits a sublinear dependence on P up to the first phase transition at 9.4 ± 0.3 GPa. However, if the gap is plotted as a function of the relative change of lattice constant (-Δa/a<sub>0</sub>) it shows, within error, a linearity with E<sub>0</sub> (eV) = 2.266 + 16.2 (-Δa/a<sub>0</sub>). The experimental results are compared to theoretical calculations based on a local empirical pseudopotential and with recently published ab initio LMTO calculations. (Author abstract) 22 refs.

## Recrystallization

**095615 GROWTH OF HgZnTe BY CAST-RECRYSTALLIZATION.** The growth of large-grained (Hg, Zn)Te ingots with mole fraction, x, of ZnTe (0.05 < x < 0.15) has been achieved by a modified cast-recrystallization (CR) technique. The recrystallization step of the CR process is performed using a high temperature gradient (10-100 K/cm), perpendicular to the ampoule axis. The homogeneity and structural, optical and photoelectrical properties of as-grown material and of material low-temperature annealed in Hg vapors have been studied. It was shown that the influence of low-temperature anneal on the properties of the material is essentially similar to that of (Hg, Cd)Te. The as-grown p-type layers are readily converted to n-type with the final donor concentrations in the mid 10<sup>15</sup> cm<sup>-3</sup> range, reflecting an uncontrolled doping level. The rate of the p-to-n-type conversion is, however, lower compared to (Hg, Cd)Te of the same band gap. The use of (Hg, Zn)Te grown by CR for IR detectors has been demonstrated. (Author abstract) 15 refs.

## Spectroscopic Analysis

**095616 TIME-RESOLVED SPECTROSCOPY OF THE LOW-ENERGY EMISSION BANDS OF HIGHLY DOPED Zn<sub>1-x</sub>Mn<sub>x</sub>S.** The luminescence excitation and emission spectra of Zn<sub>1-x</sub>Mn<sub>x</sub>S with high Mn concentration (0.01 ≤ x ≤ 0.25) is studied by time-resolved laser spectroscopy at temperatures 10 K ≤ T ≤ 300 K. Besides of the emission bands peaking at 17,000 cm<sup>-1</sup>, 15,750 cm<sup>-1</sup>, and = 13,500 cm<sup>-1</sup> a fourth band peaking in the IR at 10,600 cm<sup>-1</sup> is registered. This IR band is closely connected to two excitation bands in the UV peaking at 26,900 cm<sup>-1</sup> and 28,750 cm<sup>-1</sup> (T = 10 K, x = 0.034). Four different Mn dominated centers are distinguished, which are partly

connected by energy transfer. (Author abstract) 9 refs.

Benecke, C. (TU Berlin, Berlin, West Ger); Busse, W.; Gumlich, H.-E.; Moros, H.-J. *Phys Status Solidi B* v 142 n 1 Jul 1987 p 301-309.

**095617 NEW EMISSION BAND IN THE NEAR BAND EDGE REGION IN ZnSe SINGLE CRYSTAL.** An emission band with FWHM of 2.7 meV has been observed at 2.8002 eV. Its emission intensity is proportional to the 1.2 power of the excitation intensity. The excitation spectrum and selective excitation spectrum do not show any additional spectral structure. It is proposed that the origin of this emission is the scattering of excitons by other free particles at a structural defect with slightly lower potential for free particles and free excitons. (Author abstract) 7 refs.

Isshiki, M. (Tohoku Univ, Sendai, Jpn); Kyotani, T.; Masumoto, K.; Uchida, W.; Suto, S. *Solid State Commun* v 62 n 7 May 1987 p 487-490.

**095618 NMR STUDY OF THE ZINC CHALCOGENIDES (ZnX, X = O, S, Se, Te).** A nuclear magnetic resonance investigation of the solid zinc chalcogenides ZnX (X = O, S, Se, Te) is carried out, using the following nuclei as probes, <sup>67</sup>Zn, <sup>17</sup>O, <sup>33</sup>S, <sup>77</sup>Se, and <sup>125</sup>Te. The spectra yield nuclear quadrupole coupling constants and chemical-shift parameters for polycrystalline ZnO and ZnS in the wurtzite (hexagonal) form, and chemical shifts and linewidths for polycrystalline ZnS, ZnSe, and ZnTe in the sphalerite (cubic) form. A single crystal of ZnO is used to obtain an accurate measurement of the quadrupole coupling constant for <sup>67</sup>Zn, |e<sup>2</sup>qQ/h| = 2.4065(15) MHz at 296 K, in agreement with a recent Moessbauer-effect measurement. The electric field gradient of the wurtzite structures is analyzed with a simple ionic model, and the results are found to be in semiquantitative agreement with experiment. (Author abstract) 20 refs.

**095629 INVESTIGATION OF DEEP LEVELS IN HEAT-TREATED ZnSe CRYSTALS BY ODLTS TECHNIQUE.** Three deep acceptor levels, formed by heat-treated undoped ZnSe crystals in vacuum are found by ODLTS method. Two deep acceptor levels of them,  $E_a + 0.30\text{eV}$ ,  $E_v + 0.72\text{eV}$ , are attributed to the deep acceptor levels related to the Cu-G and Cu-R centers, respectively, which could be produced by existence of the residual copper impurity in ZnSe crystal. (Author abstract) 6 refs.

Wang, Shouyin (Acad Sinica, Changchun, China); Fan, Xiwu. *J Lumin* v 40-41 Feb 1988, Excited State Processes in Condens Matter, Proc of the Int Conf on Lumin, Beijing, China, Aug 17-21 1987 p 802-803.

**095630 PHOTO - AND ELECTROLUMINESCENCE OF ZnSe GROWN BY OMVPE.** Undoped ZnSe epilayers have grown on (100) GaAs substrates by atmospheric pressure organometallic vapor phase epitaxy (OMVPE) with dimethylzinc (DMZ) and hydrogen selenide ( $\text{H}_2\text{Se}$ ) as source. The epilayers grown under 270-325°C exhibit low resistivity of about  $1\Omega\cdot\text{cm}$ . The carrier concentration and mobility are of the order of  $10^{16}\text{cm}^{-3}$  and  $300\text{-}400\text{cm}^2\text{V}^{-1}\text{s}^{-1}$  respectively at RT. A strong NBE emission of PL and EL spectra are observed at 77K and RT respectively. (Author abstract) 5 refs.

Yang, Baojun (Acad Sinica, Changchun, China); Zhang, Jiying; Wessels, Bruce W. *J Lumin* v 40-41 Feb 1988, Excited State Processes in Condens Matter, Proc of the Int Conf on Lumin, Beijing, China, Aug 17-21 1987 p 804-805.

**095631 EFFECT OF HEAT TREATMENT ON PHOTOLUMINESCENCE AND INTERFACE PROPERTIES IN MOCVD-GROWN ZnSe ONTO GaAs AND Ge.** The effect of heat treatment on 4.2 K photoluminescence spectra in MOCVD-grown ZnSe layers onto Ga As and Ge substrates has been presented. Excitonic-emission lines in ZnSe/GaAs are markedly affected by heat treatment in  $\text{H}_2$  atmosphere and gradually shift towards lower photon energies with temperature. In contrast to that, principal bound-exciton ( $1\text{GM}$ ) line in ZnSe/Ge was not changed up to 400°C. The interdiffusion between the epitaxial layer and substrate was significantly observed. (Author abstract) 4 refs.

## Spectrum Analysis

**095633 RAMAN PROBING OF ZnTe-ZnS STRAINED-LAYER SUPERLATTICES.** ZnTe-ZnS strained-layer superlattices grown by Hot Wall Epitaxy are investigated by Raman spectroscopy. The formation of the superlattice structure is clearly observed. The line profile and the frequency shifts of LO and TO Raman modes due to elastic strain in the superlattice layers depend remarkably on the layer thickness and appear to be in compliance with theoretical calculation within the critical values of layer thicknesses. The spectra of ZnTe 10A-ZnS 10 A superlattices give an indication of folded LA phonon modes caused by the new periodicity. (Author abstract) 14 refs.

## Surfaces

**095639 RHEED OBSERVATION ON (001)ZnSe SURFACE: MBE SURFACE PHASE DIAGRAM AND KINETIC BEHAVIOR OF Zn AND Se ADATOMS.** Reflection high-energy electron diffraction (RHEED) studies have been performed on epitaxial (001)ZnSe surfaces. The phase diagram on the surface grown by molecular beam epitaxy (MBE) was obtained by observing changes of RHEED patterns as a function of beam flux ratio and substrate temperature. The desorption time of Se atoms and the adsorption time of Zn atoms were also obtained by measuring the time taken for the surface structure to change from a Se-stabilized surface to a Zn-stabilized one. The activation energy for the desorption of Se atom from a Se-stabilized surface was 1.02 eV. (Author abstract) 8 refs.

## Synthesis

**095640 INTERCALATES OF COMPOSITION  $ZnNb_{1+y}Se_2$ .** Intercalates of composition  $Zn_xNb_{1+y}Se_2$  ( $0 < x \leq 0.39$ ) have been synthesized for the first time by intercalating zinc from the vapor phase into niobium diselenide. The ranges of existence of these intercalates were determined by x-ray and quantitative chemical analyses. From the results of calculations of the electron density distribution it is shown that the intercalated zinc atoms have the coordinates (0,0,0). The statistical character of the filling of octahedral vacancies with intercalated zinc atoms is established. In Russian. 9 refs.

**095641 INTERCALATION PROCESS AND THERMAL STABILITY IN AIR OF  $Zn_xNb_{1+y}Se_2$  INTERCALATES.** During the intercalation of niobium diselenide with zinc from the vapor-gas phase the implanting of the zinc is accompanied by the liberation of selenium into the vapor-gas phase and, in addition to intercalation with zinc, self-intercalation occurs. The intercalation process occurs in two states: the formation of intercalates with a zinc content  $x=0.27-0.33$  in the surface region and subsequent advancement of the intercalate front into the bulk of the microcrystal to form a homogeneous intercalate. It is established for the first time in the case of transition metal dichalcogenide intercalates such as  $Zn_xNb_{1+y}Se_2$  that the limit of their thermal stability in air

increases linearly with an increase in the quantity of intercalated zinc. In Russian. 5 refs.

**095642 THERMODYNAMICS ANALYSIS OF THE REDUCIBILITY OF ZINC PHOSPHATE AND CADMIUM PHOSPHATE TO CORRESPONDING PHOSPHIDES.**  $Al^{11}_3B^{11}_2$  compound semiconductors, particularly Zn/Cd phosphides and arsenides have exhibited interesting properties for very promising application in devices such as solar cells, IR detectors, lasers and transducers. In this study, the reduction of  $Zn_3(PO_4)_2$  was done in vacuum at 600°C for 16h. The present note describes a critical assessment of the thermodynamics of oxidation reduction behaviour of CdO, ZnO and  $P_2O_5$  systems at various temperatures. Also taking into consideration the corresponding vapour pressure data, it has been shown that in the case of  $Zn_3(PO_4)_2$ ,  $P_2O_5$  gets reduced to phosphorus which then reacts with zinc to form  $Zn_3P_2$  in the boat while in the case of  $Cd_3(PO_4)_2$ , CdO gets reduced to cadmium and volatilizes off the system before  $P_2O_5$  could be reduced to elemental phosphorus. 21 refs.

## Thermal Expansion

**095643 LOW-TEMPERATURE THERMAL EXPANSION OF  $ZnSiAs_2$ .** The thermal expansion coefficients  $\alpha_a$  and  $\alpha_c$  of the lattice parameters a and c of  $ZnSiAs_2$  are measured in the temperature range from 30 to 300 K using the X-ray Bond method. Both  $\alpha_a$  and  $\alpha_c$  decrease with temperature and become negative at about 45 K. The results are compared with thermal expansion data for other chalcopyrite semiconductors and are discussed in terms of the principal Grüneisen parameters of these compounds. (Author abstract). 42 Refs.

## Thermal Properties See SEMICONDUCTING ALUMINUM COMPOUNDS—Thermal Properties.

## Thick Films

**095644 PHYSICAL AND ELECTRICAL PROPERTIES OF SCREEN-PRINTED  $Zn_xCd_{1-x}S$  THICK FILMS.**  $Zn_xCd_{1-x}S$  films are of considerable interest for heterojunction solar cells because their use in place of CdS permits a greater open-circuit voltage. In the present paper we report results obtained with  $Zn_xCd_{1-x}S$  films prepared by the screen-printing technique in the entire composition range of  $0 \leq x \leq 1.0$ . The lattice parameters a and c vary with x in accordance with Vegard's law. Scanning electron micrographs reveal an enhancement in porosity with increasing x. The dark electrical resistivity of the film increases with x in the range  $0 \leq x \leq 0.6$ , but beyond this range it starts decreasing. Photoconductivity is studied as a function of x. An effect of  $H_2$  annealing on the dark resistivity and photosensitivity is established. (Edited author abstract) 16 refs.

## Thin Films See Also ELECTROLUMINESCENCE; LASERS, SEMICONDUCTOR—Design; MANGANESE AND ALLOYS—Spectroscopic Analysis.

**095645 STRUCTURAL PROPERTIES OF NON-STOICHIOMETRIC ZINC OXIDE FILMS.** Authors report a study of the crystal structure and microstructure of sputtered non-stoichiometric  $ZnO_x$  thin films for which  $0.7 < x < 1$ . A substrate rf discharge was used to control film stoichiometry during deposition. All

films had a columnar microstructures, and the film surface progressed from rough to smooth with increased oxidation. X-ray diffraction analysis detected no presence of crystalline zinc in any film. The crystallite size, strain and orientation of  $ZnO$ , detected in all films, was dependent on film composition and substrate rf discharge power. A model of film structure incorporating the competing effects of ion bombardment (causing amorphization) and increased oxygen content (creating improved crystallinity and orientation) is used to explain the observed variation of  $ZnO_x$  crystal structure. (Author abstract) 15 refs.

**095647 CRYSTALLOGRAPHIC CHARACTERIZATION OF  $ZnS_{1-x}Se_x$  PITAXIAL FILMS.** Crystalline quality of  $ZnS_{1-x}Se_x$  films grown on GaAs substrates has been investigated in detail using the X-ray double-crystal method. Respective fluctuations in orientation and spacing of lattice planes are measured separately. It is shown that the crystalline quality of  $ZnS_{1-x}Se_x$  films is noticeably affected by the fluctuation in orientation caused by lattice mismatch and partly by the fluctuation in spacing which may be associated with an inhomogeneous distribution of Se and S atoms. Improvement of the quality by lattice matching is due to a reduction of fluctuation in orientation. (Author abstract). 7 Refs.

**095648 EFFECT OF HEAT TREATMENT ON THE CRYSTALLINE QUALITY OF ZnSe EPILAYERS GROWN BY METALORGANIC VAPOR PHASE EPITAXY.** Thermal stability of ZnSe epilayers grown at the low growth temperatures of 250-300°C by MOVPE depends heavily on growth conditions, particularly the reactor pressure. The high density of deep centers is generated from the surface and diffuses into the epilayer by treating the epilayer at a temperature above 600°C under  $H_2$  atmosphere only. However, the increase of deep centers is effectively prevented by mixing dimethylzinc (DMZ) in the atmosphere even at the high temperature of 700°C. It is probable that the partial pressure of Zn vapor in the ambience would suppress the generation of Zn vacancies at the high temperature. (Edited author abstract). 8 Refs.

Yodo, Tokuo (Nippon Sheet Glass Co, Tsukuba city, Jpn); Yamashita, Ken. *Jpn J Appl Phys Part 2* v 27 n 5 May 1988 p 903-905.

**095649 NITROGEN DOPED p-TYPE ZnSe LAYER GROWN BY METALORGANIC VAPOR PHASE EPITAXY.** Nitrogen-doped ZnSe layers have been grown on (100) GaAs substrates by metalorganic vapor phase epitaxy using  $NH_3$  as the doping material. The N-doped layers exhibit a strong free-to-acceptor transition emission at 77 K and a strong acceptor bound-exciton emission line at 15 K. The layers with a high doping level, which exhibit broader excitonic emission lines, indicate p-type conduction with low resistivities from  $10^2$  to  $10^3 \Omega \cdot cm$ , carrier concentrations of the order of  $10^{14} cm^{-3}$  and mobilities

from 20 to 50 cm<sup>2</sup>/Vs. Current-voltage characteristics of the N-doped ZnSe/n-GaAs heterojunctions conform to the p-type conduction. (Author abstract). 8 Refs.

Ohki, Akira (NTT, Tokai, Jpn); Shibata, Noriyoshi; Zembutsu, Sakae. *Jpn J Appl Phys Part 2* v 27 n 5 May 1988 p 909-912.

**095650 GROWTH OF HEXAGONAL ZnS THIN FILMS BY MOCVD USING CS<sub>2</sub> GAS AS A SULFUR SOURCE.** High-quality ZnS films have been grown on glass and (111)Si substrates in the temperature range of 300-450°C by a low-pressure MOCVD technique using carbon disulfide (CS<sub>2</sub>) as a sulfur source. The diethylzinc-CS<sub>2</sub> (DEZ-CS<sub>2</sub>) system did not exhibit a premature reaction. The reaction process in this system is described. Films grown on glass substrates were hexagonal ZnS with a high degree of c-axis orientation. The full width at half maximum of the X-ray diffraction peak of 0.18° was obtained for the films grown at a substrate temperature of 400°C with a [CS<sub>2</sub>]/[DEZ] flow rate ratio of 10. Bright orange electroluminescence was observed in a thin film electroluminescent device with a manganese-doped MOCVD-grown ZnS emitting layer. (Author abstract) 13 refs.

Takata, S. (Kanazawa Inst of Technology, Kanazawa, Jpn); Minami, T.; Miyata, T.; Nanto, H. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 257-262.

**095651 ZINC PHOSPHIDE THIN FILMS GROWN BY RF SPUTTERING.** Zinc phosphide (Zn<sub>3</sub>P<sub>2</sub>) thin films have been prepared by RF sputtering in either Ar, H<sub>2</sub>, or PH<sub>3</sub> atmospheres. The Zn<sub>3</sub>P<sub>2</sub> films were deposited on glass substrates at RF power P<sub>s</sub> of 50-300 W, substrate temperature T<sub>s</sub> of 60-250°C, and total pressure up to 1 Torr. The Zn<sub>3</sub>P<sub>2</sub> films grown in PH<sub>3</sub> show a strongly preferred orientation; the c-axis is aligned perpendicular to the glass substrates, whereas the films grown in Ar and H<sub>2</sub> are amorphous. The crystallinity of Zn<sub>3</sub>P<sub>2</sub> films grown in PH<sub>3</sub> depends strongly on both PH<sub>3</sub> pressure P<sub>p</sub> and RF power: below P<sub>s</sub> = 150 W the films are amorphous while they are polycrystalline above it; the Zn<sub>3</sub>P<sub>2</sub> films are polycrystalline below P<sub>p</sub> = 0.6 Torr, whereas they are amorphous above it. The X-ray fluorescence analysis and EPMA indicate Zn<sub>3</sub>P<sub>2.03</sub> for the films deposited at P<sub>p</sub> = 0.2 Torr, P<sub>s</sub> = 200 W, and T<sub>s</sub> = 100°C. Optical measurements show that film has a 1.5 eV direct bandgap. (Author abstract) 11 refs.

**095652 ZINC PHOSPHIDE THIN FILMS GROWN BY LOW PRESSURE VAPOR PHASE DEPOSITION.** Zinc phosphide (Zn<sub>3</sub>P<sub>2</sub>) thin films have been grown by a low pressure vapor phase deposition technique at a pressure of 5-10 Torr. The Zn<sub>3</sub>P<sub>2</sub> thin films deposited at the optimum substrate temperature T<sub>s</sub> of 300-350°C show good crystallinity and stoichiometry; the Zn<sub>3</sub>P<sub>2</sub> films are preferentially oriented in the [004] direction on glass substrates. EPMA indicates a composition of Zn<sub>3</sub>P<sub>1.95</sub> for the Zn<sub>3</sub>P<sub>2</sub> films deposited at T<sub>s</sub> = 350°C with a grain size of 3-5 μm. A fundamental direct absorption edge of Zn<sub>3</sub>P<sub>2</sub> films has been deduced from optical transmission and reflection measurements, and is 1.45 eV at room temperature. (Author abstract) 8 refs.

Suda, Toshikazu (Inst of Vocational & Technical Education, Sagami-hara, Jpn); Nishimoto, Toshiaki; Kurita, Shoichi. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 430-435.

**095653 EFFECT OF CO-EVAPORATION ON ZnS:Mn ELECTROLUMINESCENT CHARACTERISTICS.** We present a discussion of the brightness-voltage (B-V) response of thin-film electroluminescent (TFEL) devices prepared by the simultaneous evaporation of ZnS

and Mn (or MnS) using two separate sources. Crystal structure, threshold voltage, saturation brightness, and memory margin of the B-V characteristics have been studied as a function of the deposition rate of dopant material relative to ZnS. Optimum annealing conditions of the devices are also given. These results indicate that co-evaporation can be advantageously employed to fabricate memory TFEL display devices with excellent characteristics. (Author abstract) 14 refs.

## Vapor Deposition

**095654 USE OF ETHYLIODIDE IN PREPARATION OF LOW-RESISTIVITY N-TYPE ZnSe BY METALORGANIC VAPOR PHASE EPITAXY.** Ethyl iodide is shown to be useful as a dopant for growing high-quality n-type ZnSe layers by metalorganic vapor phase epitaxy. Low-resistivity ZnSe single-crystal layers with  $\rho < 0.002 \Omega \cdot \text{cm}$  and  $n > 10^{19} \text{ cm}^{-3}$  have been grown on (100) GaAs substrate. The grown layers, with an appropriate doping level ( $n$  approximately  $10^{18} \text{ cm}^{-3}$ ), show a strong blue near-band-edge photoluminescence at room temperature. The emission intensity from the layer is several hundred times stronger than that from the undoped ZnSe. (Author abstract) 7 refs.

Shibata, Noriyoshi (NTT, Tokai, Jpn); Ohki, Akira; Zembutsu, Sakae. *Jpn J Appl Phys Part 2* v 27 n 2 Feb 1988 p 251-253.

**095655 PHOTOLUMINESCENCE DUE TO LATTICE-MISMATCH DEFECTS IN HIGH-PURITY ZnSe LAYERS GROWN BY METALORGANIC VAPOR PHASE EPITAXY.** High-purity ZnSe layers grown by metalorganic vapor phase epitaxy exhibit an unusually strong luminescence band at 2.60 eV (Y band), which is extremely sensitive to residual impurity concentration. Y emission depends on the lattice mismatch between the epilayer and substrate. The emission decreases with the use of a lattice-matched In<sub>x</sub>Ga<sub>1-x</sub>As substrate. With the GaAs substrate, the emission intensity varies with layer thickness reflecting lattice relaxation in the ZnSe/GaAs structure. (Author abstract) 9 refs.

Shibata, Noriyoshi (NTT, Tokai, Jpn); Ohki, Akira; Zembutsu, Sakae; Katsui, Akinori. *Jpn J Appl Phys Part 2* v 27 n 3 Mar 1988 p 441-443.

**095656 THERMOELASTIC STRAIN IN ZnSe FILMS GROWN ON GaAs BY METALORGANIC VAPOR PHASE EPITAXY.** It has been observed that ZnSe lattices grown on (100) GaAs by metalorganic vapor phase epitaxy deform as growth temperature increases. The lattice parameter variation corresponds to calculated thermoelastic strain due to a mismatch in the thermal expansion coefficient between ZnSe and GaAs. In-plane tensile strain in ZnSe films is found to cause a spectral position shift in photoluminescence to longer wavelengths with increasing growth temperature. This shift can be explained by the dependences of energy gap variation on thermoelastic strain. (Author abstract) 12 refs.

Shibata, Noriyoshi (NTT, Tokai, Jpn); Ohki, Akira; Zembutsu, Sakae; Katsui, Akinori. *Jpn J Appl Phys Part 2* v 27 n 4 Apr 1988 p 487-489.

**095657 OMVPE OF Zn-BASED II-IV SEMICONDUCTORS USING METHYLMERCAPTAN AS A NOVEL SULFUR SOURCE.** The use of a novel sulfur source, methylmercaptan, CH<sub>3</sub>SH (MSH), for OMVPE growth of ZnS and Zn(S,Se) has been developed for the first time. Gas-phase prereaction was not observed, and the growth temperature of ZnS was successfully reduced, compared with growth using dialkyl-compounds. Zn(S,Se) alloy epilayers lattice-matched to GaAs substrates had specular surface morphology, excellent crystallographic properties, and showed strong excitonic emissions but weak intensities of deep level emissions. (Author abstract) 12 refs.

Fujita, Shigeo (Kyoto Univ, Kyoto, Jpn); Isemura, Masashi; Sakamoto, Takao; Yoshimura, Naomichi. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 263-267.

**095658 EFFECTS OF LATTICE-MATCHED In<sub>x</sub>Ga<sub>1-x</sub>As SUBSTRATES ON ZnSe GROWTH BY METALORGANIC VAPOR PHASE EPITAXY.** Zinc selenide (ZnSe) epitaxial layers have been grown by metalorganic vapor phase epitaxy on lattice-matched In<sub>x</sub>Ga<sub>1-x</sub>As substrates with component values of  $x$  ranging from 0.034 to 0.047. It has been shown that a lattice mismatch reduction is essential for growing high-quality epilayers. Crystallographic properties of the layers are improved over those of ZnSe/GaAs structures. Intensities of excitonic emissions in the photoluminescence spectra increase with lattice matching. The energy position of the excitonic emission lines is almost constant for different thicknesses of the ZnSe layers. (Author abstract) 9 refs.

**095659 GROWTH OF HIGH-QUALITY ZnSe BY MOVPE ON (100) ZnSe SUBSTRATE.** In this paper, we report the MOVPE growth of undoped ZnSe layers on (100) ZnSe substrates cut from ingots grown by iodine vapor transport. The purpose of the present paper is to show the effects of heat treatment of the substrates before growth under various atmospheres, on the morphological, crystallographic and photoluminescent properties, and the optimum cleaning procedure of the substrates to remove surface contaminants and oxide layers. 14 refs.

Yodo, T. (Nippon Sheet Glass Co, Toyosatomachi, Jpn); Koyama, T.; Yamashita, K. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 273-278.

**095660 EFFECT OF SUBSTRATE AUTODOPING ON MOVPE-GROWN ZnS<sub>1-x</sub>Se<sub>x</sub> AND ZnSe ANALYSIS BY PHOTOLUMINESCENCE (PL) AND SECONDARY ION MASS SPECTROMETRY (SIMS).** The effect of substrate outdiffusion on the optical properties and compositional integrity of high quality ZnSe and ZnS<sub>1-x</sub>Se<sub>x</sub> ( $0 < x < 1$ ) grown by atmospheric pressure metalorganic vapour phase epitaxy (MOVPE) was investigated by low temperature photoluminescence (PL) and secondary ion mass spectrometry (SIMS) depth profiling analyses. Substrate outdiffusion was found to occur in the ZnSe/GaAs and lattice mismatched ZnS<sub>1-x</sub>Se<sub>x</sub> ( $0 < x < 1$ )/GaAs systems but not appreciably in the ZnSe/Ge and lattice matched ZnS<sub>1-x</sub>Se<sub>x</sub> ( $x = 0.06$ )/GaAs as indicated by diffuse and abrupt compositional SIMS depth profiles respectively. Low temperature PL measurements indicated changes in the main excitonic recombination transitions for ZnSe/GaAs. In particular the emphasis changes from the I<sub>2</sub><sup>Ga</sup> donor bound exciton emission for thin layers to the I<sub>x</sub> native donor bound exciton emission for thicker layers. The I<sub>2</sub><sup>Ga</sup> donor bound exciton peak is also dominant in the lattice mismatched ZnS<sub>1-x</sub>Se<sub>x</sub> ( $0 < x < 1$ ). (Author abstract) 20 refs.

## Vibrations

**095661 HYDROGEN-INDUCED LOCALIZED VIBRATIONAL MODE IN PROTON IMPLANTED ZnSe SINGLE CRYSTALS.** Infrared transmission spectra of proton implanted ZnSe single crystals exhibit a localized vibrational mode at 2116 cm<sup>-1</sup> which is ascribed to Se-H bond vibrations. The dependence of the integrated absorption A of this mode on the proton fluence D follows the relation  $A \approx D^n$  with  $n=0.46$ . The results of ZnSe are compared with previous measurements

on proton implanted III-V compounds. (Author abstract) 9 refs.

**095665 PLASMA ETCHING IN SEMICONDUCTOR FABRICATION.** This book reviews and reports on research studies of plasma etching used in the fabrication

of semiconductor devices. The etching characteristics of materials widely used in device fabrication, such as silicon, silicon dioxide, photoresist and aluminum films, have been given most attention. An extensive review is made of etching mechanisms in halogenated plasmas and of reactor architecture. The book provides process information and an introduction to plasma generation, probe theory and photoresist chemistry. Details are given of plasma etching processes and the effects of changes of such parameters as rf applied frequency, gas flow, gas pressure and oxygen/hydrogen additions. The work is based on the original thesis submitted to the University of Sussex for a post-graduate degree and is presented as a book for more widespread interest.

Morgan, Russ A. (Univ of Sussex, Brighton, Engl). *Plasma Etching in Semicond Fabr* Publ by Elsevier (Plasma Technol, v 1), Amsterdam, Neth and New York, NY, USA, 1985 316p.

**095666 PROSPECTS FOR DEVELOPMENT OF HEAVY-CURRENT SEMICONDUCTOR DEVICES.** The state of the art and immediate prospects for development of basic classes of discrete heavy-current semiconductor devices are discussed. The limiting characteristics that have now been achieved for devices based on silicon, gallium arsenide, and silicon carbide are cited. (Author abstract) 13 refs.

Grekhov, I.V. *Sov Electr Eng* v 57 n 8 1986 p 1-5.

**095667 EFFECT OF POLYSILICON GATE PATTERN/DOPING SEQUENCE ON GATE OXIDE DEGRADATION.** This work was done to determine the extent to which gate oxide degradation could be prevented by doping the polysilicon before patterning, thus eliminating the edge effect during the doping process. That is, dope the polysilicon before patterning. Such a process would have utility in cases where the doping level or type is different in the gate as opposed to the source/drain and could therefore be done before patterning the gate. Capacitor yields were investigated in this regard to show the extent to which they were affected by the doping/patterning sequence. Benefits were achieved by patterning the polysilicon after the doping process. 9 refs.

**095668 SELF-ALIGNED CONTROLLED COLLAPSE CHIP CONNECT (SAC4).** The authors have developed a self-aligned controlled collapse chip connect (SAC4) scheme for the precise positioning of device chips on a Si interconnect wafer, which has the following advantages: (i) The self-alignment is maintained in all three dimensions so that the chip to wafer spacing is established lithographically instead of depending on the critical control of the solder collapse. (ii) Patterning in the active area on both the chip and the wafer is planar with no inherent steps or gaps to be bridged. (iii) Because of the precise control of the chip to wafer distance, there can be direct access to any spot on a chip for I/O solder pads eliminating the need to bring all I/O pads to the chip edge which is implicit in the C4 scheme. This scheme is not limited to Si devices and boards. 6 refs.

**095670 FLUID DYNAMIC PROBLEMS IN THE SEMICONDUCTOR INDUSTRY.** In the semiconductor industries, control of the manufacturing environment has become important because of rapid changes in device miniaturization and the utilization of wafers with large diameters. New problems have arisen, such as how to prevent minute dust particles from diffusing over wafers, or how to form thin films with a uniform thickness over large area wafers. To cope with such problems, the establishment of new analytical and control techniques is required. This report discusses various fluid dynamic problems involved with semiconductor fabrication. These problems are compared with situations treated with conventional fluid dynamic approaches. Our discussion focuses on (1) analysis of the air flow in clean rooms and inside semiconductor manufacturing apparatus, (2) predicting the thickness of a film formed on a wafer, (3) analysis of the behavior of dust particles in air flows with different levels of pressure, and (4) applicable methods to measure particle size and motion. (Edited author abstract) 21 refs.

Kobayashi, T. (Univ of Tokyo, Jpn); Kobayashi, S.; Kobayashi, J. *J Fluid Control* v 17 n 4 1987 p 20-37.

**095671 EFFECTS OF CONTAMINATION ON SEMICONDUCTOR MANUFACTURING YIELD.** The challenges associated with controlling particulate and chemical contamination to achieve high semiconductor device yields are demonstrated with data showing the influence of cleanroom air, semiconductor processes and tools, gases, chemicals, and DI water. Because typical film thicknesses are much smaller than pattern feature sizes, defects that are as small as one hundredth of the lithographic dimension must be controlled. Scaling device dimensions by a factor of 1/3 to 1/2 will require almost a factor of 10 reduction of particulate levels in order to maintain the prescaling yield. To achieve a 78 percent yield of (0.25 defects/cm<sup>2</sup>) in a typical submicron, process containing 250 process steps, each step must contribute no more than 0.001 killer defects/cm<sup>2</sup> on average. Storage of wafers for 1 hr in a Class 1 vertical laminar flow cleanroom is sufficient to reach this level. Considerably more defects are introduced in other process steps involving automated tools or chemical/gas exposure. As device dimensions are reduced, the contamination associated with liquids will become relatively more important than that from gases and cleanroom air. (Author abstract) 67 refs.

Osburn, Carlton M. (North Carolina State Univ, Raleigh, NC, USA); Donovan, Robert P.; Berger, Henry; Jones, Gary W. *J Environ Sci* v 31 n 2 Mar-Apr 1988 p 45-57.

**095672 SILO ISOLATION TECHNIQUE: A STUDY OF ACTIVE AND PARASITIC DEVICE CHARACTERISTICS WITH SEMI-RECESSED AND FULLY-RECESSED FIELD OXIDES.** A typical NMOS process with Sealed Interface Local Oxidation (SILO) technology as the device isolation technique was used to fabricate active and parasitic devices. The electrical characteristics are presented. The influence of the boron channel stop lateral diffusion into the active region on the narrow channel effect, the effective channel width, and the subthreshold current is discussed. The low leakage current of the subthreshold characteristics demonstrates the integrity of the isolation technique. Electrical measurements on N+P diodes with different perimeters reveal a weak defect generation during field oxidation. The results indicate that the fully-recessed SILO process is capable of replacing the conventional LOCOS technique in the micron and submicron technologies, with advantage in the planarity of the isolation process. (Author abstract) 17 refs.

Coppee, J.-L. (Univ Catholique de Louvain, Louvain-La-Neuve, Belg); Van de Wiele, F. *Solid State Electron* v 31 n 5 May 1988 p 887-891.

**095673 FABRICATION OF NANOMETER WIDTH GaAs/AlGaAs AND InGaAs/InP QUANTUM WIRES.** Starting from GaAs/AlGaAs and InGaAs/InP quantum well structures, we have produced quantum wires with

lateral dimensions down to 30 nm, using direct electron beam writing and several dry etching techniques. Investigating the photoluminescence efficiency of wire structures as a function of the linewidth, we find a steep decrease with decreasing linewidth in the case of the GaAs/Al-GaAs system, whereas for InGaAs/InP the decrease is much smaller. This luminescence decay can be interpreted as a result of the surface recombination at the sidewalls, which gains growing influence with decreasing linewidth. (Author abstract) 10 refs.

**095674 NATURE OF TITANIUM-CONTAINING FILMS FORMED ON POLYMER SURFACES BY REACTIONS OF SORBED WATER WITH  $TiCl_4$ .** This paper reports the reactions of gaseous  $TiCl_4$  with various polymers equilibrated at 50% and 0% RH. The reactions were studied using thickness measurements,  $O_2$  RIE rates, Rutherford backscattering spectroscopy (RBS) and X-ray photoelectron spectroscopy (XPS). The results show that at 0% RH, hydrophilic polymers such as hard-baked HPR-206 resist (HB206) have very little ( $< 2 \times 10^{14}$  atoms/cm<sup>2</sup>) Ti at the polymer surface and are readily etched by  $O_2$  RIE. In contrast, hydrophobic polymers such as polystyrene (PS) react readily with  $TiCl_4$  to give a measurable thickness increased, are etched at a reduced  $O_2$  RIE rate and appear to have Ti distributed throughout the film. (Edited author abstract) 13 refs.

**095675 USE OF ORGANOSILICON POLYMERS IN MULTILAYER PLASMA RESIST PROCESSING.** The unique resistance of organosilicon polymers to oxygen plasmas has led to their widespread use in multilayer resist processing. A study of their etching properties shows a correlation between their structure and etching characteristics. Often, these characteristics are obtained by means of laser interferometric techniques. Using a model of this laser signal we have identified various processes which combine to form an oxygen plasma resistant layer atop these organosilicon polymers. In particular, we have discovered that the etching characteristics of these polymers are relatively independent of the specific structure. Rather, the silicon content of these polymers plays the dominant role in providing resistance to these plasmas. For polymers having a high silicon content, the laser signal is regular and sinusoidal; for lower concentrations ( $< 10\%$ ), the laser signal shows irregularities which can be explained by means of the model. (Edited author abstract) 9 refs.

**Cleaning** See INTEGRATED CIRCUIT MANUFACTURE—Cleaning.

## Computer Aided Manufacturing

**095677 LOW-THERMAL-BUDGET PROCESS MODELING WITH THE PREDICT COMPUTER PROGRAM.** Low-thermal-budget processing models have been developed that are applicable to a broad range of ion-implantation and annealing conditions. The cases discussed here include low-temperature furnace annealing of B implants, preamorphization or postamorphization using  $Si^+$  or  $Ge^+$  implants, and rapid thermal annealing of low-dose and high-dose implants. Annihilation of implant damage is accounted for through activated annealing models. Damage type and location in depth are important in understanding enhanced or retarded diffusion of dopants. Damage and diffusion models have been incorporated in the PREDICT program, and example calculations are compared with measurements. 28 refs.

## Computer Simulation

**095679 MICROCOMPUTER SIMULATION IMPROVES PRODUCTION SCHEDULING FOR MICROELECTRONICS MANUFACTURERS.** A simulation model was designed and implemented with the purpose of improving the scheduling, control, and production management of the manufacturing line for a medium size silicon wafer manufacturer. The simulation model was designed to be interactive on a microcomputer, easily adaptable to other similar manufacturing environments, and readily usable at various decision levels ranging from manufacturing floor supervisors to upper management. It can easily interface with other decision analysis packages to assist in a variety of decision processes throughout the plant. (Edited author abstract) 19 refs.

Economides, Spyros (California State Univ, Hayward, CA, USA); Cunningham, Frank. *J Manuf Syst* v 6 n 4 1987 p 267-275.

**095680 MULTIPLE-ZONE SINGLE-MASK JUNCTION TERMINATION EXTENSION - A HIGH-YIELD NEAR-IDEAL BREAKDOWN VOLTAGE TECHNOLOGY.** The junction termination extension (JTE) technique is investigated by computer simulation and experimentally. A multiple-zone JTE can be fabricated with a well-controlled single ion-implantation through a single mask with laterally variable transparencies. Analog I-V trace records of over 40,000 samples were obtained for analysis. By grouping 49 JTE designs on separate regions of the wafer, the effects of the JTE variations and the material variations are separated. The measured JTE performance agrees well with the computer results. A multiple-zone JTE of sufficient size achieves an essentially ideal breakdown voltage unaffected by even a factor of two in ion-implant dose variations. The JTE performs well on both p-type and n-type wafers. A best design has been applied to several lots of power devices, and a yield of 99.5% having breakdown-voltage values within 10% of the ideal has been obtained. 6 refs.

**Contamination** See Also INTEGRATED CIRCUIT MANUFACTURE—Contamination; SEMICONDUCTING SILICON.

**095681 ULTRA-PURE WATER FOR THE SILICON CHIP INDUSTRY.** The author attempts to define and explain the constraints placed on the species and levels of impurities in ultra-pure water and to suggest how they may vary in the future. Turning to the contaminants, they are categorised. The contaminants include ionic species, organics, particulates, bacteria and pyrogens. The design of a very clean water distribution system is given.

McCartney, Bill (Motorola Semiconductor Div, East Kilbride, Scotl). *Chem Eng (London)* n 432 Jan 1987 p 24-26.

**095682 CLEANING A CLEANROOM.** The authors examine cleaning methods and solutions. The ideal solutions for removal of particles and chemicals are outlined along with the properties of commonly used disinfectants. Methods for cleaning a cleanroom are presented. Antistatic agents are also discussed. 2 refs.

Whyte, W.; Donaldson, Norman. *Microcontamination* v 5 n 11 Nov 1987 p 49-53.

**095683 TREND TOWARD CLASS 10 - 100 CLEANROOMS CHALLENGES CONSTRUCTION CONTRACTORS.** The purpose of this study is to highlight some of the difficulties and trends in the cleanroom construction industry. Overall, the underlying trend is toward additional and cleaner space, but in smaller segments. This is seen in a variety of circumstances. First, both small and large companies are planning or contemplating additional space. The smaller end-user is more often considering space at a higher particle level; the larger company, particularly in the microelectronics industry, is looking at cleaner space (Class 100 or better). The various stages of cleanroom construction are examined. It is shown that the construction of the cleanroom interior can be achieved only by using proven cleanroom construction techniques and quality control measures. Since this fact is becoming better known within the industry, owners are adjusting their approach to cleanroom construction services.

Baillargeon, Paul (Environmental Interiors Inc, Hudson, NH, USA). *Microcontamination* v 6 n 7 Jul 1988 p 26-32.

**095684 SUPER CLEANROOM TECHNOLOGY: A HIGH-TECH BALANCING ACT.** Results are presented of recent air filtration and airflow control technology R&D, both of which are key factors in super cleanroom design. Total uniform downflow and clean tunnel flow are discussed. The super cleanroom (SCR) system is outlined. The SCR system is an example of the new technologies being applied to the actual designing and engineering of super cleanrooms in semiconductor facilities. The ability to pretest cleanroom components and to simulate particular cleanroom setups or conditions prior to engineering and construction is a major advantage of the cleanroom laboratory facility. To maintain back-end price competitiveness and reliable production, two key requirements of future cleanroom systems will be localization of super-clean spaces and automation of wafer handling.

Suzuki, Yoshinobu (Shimizu Corp, Tokyo, Jpn); Oikawa, Susumu; Sekiguchi, Takeshi. *Microcontamination* v 6 n 9 Sep 1988 p 59-65.

**095685 IS THERE A LIGHT AT THE END OF THE TUNNEL?** The author outlines factors that need to be considered when determining the type, properties and materials that are suitable for cleanroom garments. Garment function, fabric evaluation are examined along with garment drying and evaluation. It is shown that there is no question that the PTFE material is best in terms of low particle shedding. However, PTFE garments are

expensive, and users will have to determine whether the difference between the nonwoven polyolefin and the PTFE is cost effective. The best of garments will be of limited value if the masks, gloves, and head coverings are not properly designed and used. It might be possible to improve the performance of the woven polyester garment by providing a small battery-driven suction blower to remove hot air and moisture. 5 Refs.

Hoenig, Stuart A. *Microcontamination* v 6 n 9 Sep 1988 p 18,20-24.

## Doping

**095686** AVTOMATIZIRANO DOLOCANJE IMPLANTACIJSKEGA PROFILA S CU METODO. [Automatic CV Measuring Technique for Ion Implanted Profiles]. An automatic on-line capacitance-voltage (CV) doping profile measuring technique is described, that allows measurements of concentration profiles in depths below the silicon surface greater than 2 Debye lengths. Despite its limitations, which are described, the method allows characterization of water fabrication processes during implantation. (Edited author abstract). 4 Refs. In Slovenian.

**Equipment** See Also INTEGRATED CIRCUIT MANUFACTURE—Contamination.

**095687** WAFER FABRICATION EQUIPMENT FIVE YEAR FORECAST. Concerning year-to-year trends for the industry as a whole, the five-year forecast in January 1988 is fundamentally the same as the picture presented last January. We had expected the turnaround in wafer fab equipment to occur earlier than it actually appeared, and we had predicted a 14 percent increase in 1987 spending for front end equipment. Because of the delayed turnaround, it looks like 1987 spending will actually be up about 5 percent. Last year we projected strong growth for the years 1988-1991 with the exception of a low growth period in 1989. At present we see no fundamental change in this scenario. Indeed, our optimistic five year forecast stands on even firmer ground this January. The semiconductor industry has emerged from its recession, the slack in capacity is being taken up and, in fact, new capacity has to be added to meet the world's voracious appetite for semiconductor devices.

Grenier, Joseph. *Solid State Technol* v 31 n 1 Jan 1988 p 67-70.

**095688** INFRARDECE ZGANJE DEBELOPLASTNIH MATERIALOV. [Infrared Firing of Thick Film Materials]. Thick film conductors and resistors were fired in an infrared belt furnace. Sheet resistivities of conductors were similar to resistivities of samples, fired in a 'conventional' belt furnace while the adhesion strength, measured by a peel test, was lower. Sheet resistivities of IR fired resistors were different and TCRs higher than those of 'conventional' fired resistors while the resistivity drift of aged resistors was similar. With different times at the highest temperature the TCRs can be optimized. (Edited author abstract). 8 Refs. In Slovenian.

**Etching** See Also PLASMAS—Etching; SEMICONDUCTING SILICON—Etching; TRANSISTORS, FIELD EFFECT—Contacts.

**095689** PRELIMINARY INVESTIGATION OF THE CONTAMINATION OF SEMICONDUCTOR PROCESS PUMP OIL BY HALOGENATED ORGANIC COMPOUNDS. Plasma etching is the controlled, preferably uniform, removal of layers of the material from a silicon wafer. In a plasma etcher, the wafers are placed in a vacuum with a controlled flow of

process gases. The mixture of process gases is irradiated with radio frequency radiation, usually at 13.56 MHz. Upon irradiation with the rf energy, the process gases are converted to a plasma, 'an ionized gas containing neutrals, ions and electrons'. There are many types of vacuum oils currently used in the semiconductor industry, including the perfluoroalkyl-polyethers (PFAPE) and the perfluoropolyethers (PFPE), which were the oils investigated in this paper. The chemistry of the vacuum oil decomposition and contamination is an area which requires further investigation due to the potential for worker exposure during pump maintenance. This paper reports on a study to determine the identity and quantity of organic vacuum oil contaminants in used plasma etch process pump oils. 13 refs.

**095690** ANHYDROUS HF ETCHING OF NATIVE SiO<sub>2</sub>: APPLICATIONS TO DEVICE FABRICATION. A gaseous anhydrous HF/water vapor process has been developed that etches native oxide films at ambient temperature and pressure, without plasmas, and without the need for a subsequent rinse/dry. It is an isotropic etch with properties similar to a wet HF process. Using high purity gases and components, particles are controlled to levels that are known to obtain hydrophobic surfaces. Metallic impurities are not added by this process, but neither are they significantly reduced since volatile species are not formed at this temperature. The process can be used in applications where there is a need to remove the native oxide of silicon and where it is presently done with diluted HF dip and a rinse/dry. 16 refs.

Novak, Richard E. (FSI Int Inc). *Solid State Technol* v 31 n 3 Mar 1988 p 39-41.

**095691** CONTROLLED UNDERCUTTING OF V-GROOVE CHANNELS FOR INP BY PHOTORESIST ETCH MASK. A photoresist etch mask process has been developed for the etching of v-grooves in InP (001) for channelled substrate laser growth. The relationship between the photoresist (PR) mask undercutting and the dehydration bake temperatures, the postbake temperatures, and the photoresist thicknesses were studied. The native oxide growth during the bake processes was believed to give the extra large undercut. (Author abstract) 14 refs.

## Ion Implantation

**095692** HIGH ENERGY ION IMPLANTATION. Still limited to R&D at all but a handful of companies, high energy ion implantation is emerging as powerful technique for implanting dopants 2 μm or more below the wafer surface. In the fabrication of deep CMOS wells, for example, high energy ion implantation is much more efficient than the traditional pre-dep and drive-in, and can also produce retrograde wells. The ability to produce such wells, where the doping concentration increases from the value at the surface to a peak below the device region, is significant, since such wells strongly reduce the susceptibility to latch-up. 13 refs.

## Ion Sources

**095693** FURTHER IMPROVEMENTS IN END POINT DETECTION USING A WIDE ANGLE ION BEAM SOURCE. In the fabrication of multilayer or hybrid semiconductor devices, it is often necessary for

connections to be made vertically through the structure to predetermined depths and at precise locations on the device. This paper outlines the improvements in end point detection resolution that can now be achieved with the development of an axial filter and the inclusion of a particle counter to increase sensitivity. (Author abstract).

**Laser Applications** See Also CHEMICALS—Laser Applications.

**095694** LASER-BEAM-INDUCED RECRYSTALLIZATION OF SILICON AND ITS APPLICATION TO SILICON-ON-INSULATOR TECHNOLOGY. In this approach to semiconductor device fabrication technology a thin film of polycrystalline silicon deposited on an insulating substrate is converted to a uniform monocrystalline layer by means of laser-induced micro-zone melting. By control of experimental conditions it is possible to obtain device-quality dielectrically-isolated thin films of silicon. The defects normally found in the recrystallized material are periodic arrays of dislocations forming low-angle subgrain boundaries. The origin and control of these defects, which have only minor effects on the majority-carrier transport properties, are described. The properties of MOS transistors fabricated in this material are comparable to those of devices fabricated in single-crystal silicon wafers. (Edited author abstract) 34 refs.

**Materials** See Also INTEGRATED CIRCUIT MANUFACTURE—Optimization; SEMICONDUCTING SILICON COMPOUNDS—Chemical Vapor Deposition.

**095696** CONTROLLING COSTS IN CHEMICAL DISTRIBUTION SYSTEMS. The author discusses the cost advantages of purchasing chemicals in 55-gallon drums or even larger tanker-truck bulk loads instead of the standard one-gallon glass or polyethylene bottle. A typical front-end facility operating at 2500 four-inch wafer starts a week could realize potential savings of more than \$1500 a day in direct product cost savings and related labor expenditures by purchasing chemicals in 55-gallon drums. Savings would be even more impressive when factoring in tanker-truck bulk load prices. The major disadvantages of using bottles are discussed. The use of low-particulate chemicals in the semiconductor industry is increasing, although the cost of the submicron-filtered, prepackaged chemicals has limited their use in high volumes. Low-particulate materials generally are priced at two to three times the cost of semi-grade materials. However, equipment has recently been developed that totally eliminates the need for bottles. Instead, a continuous pipeline carries chemicals from the supplier to the wafer using fluoropolymer piping, baths, and wafer carriers.

Castellano, Robert N. (Information Network, San Francisco, CA, USA). *Microcontamination* v 5 n 11 Nov 1987 p 30, 32, 34.

**095697** WAFER PROCESSING AND MATERIALS. Despite the recent severe downturn in the semiconductor industry, improvements in device, circuit and process technologies have accelerated over the last two years.

Examples of this remarkable progress are milestones of the recent past and harbingers for the immediate future. This forecast article is limited to major trends and changing requirements, over the next five years, in the mainstream of semiconductor manufacturing, and to related materials and equipment issues; we focus on the areas of greatest need or opportunity. Our premise is: What modifications and innovations will likely continue or follow from changes in device and integrated circuit (IC) structures?

Kopp, Robert J. (Kopp Semiconductor Engineering, Albuquerque, NM, USA). *Semicond Int* v 11 n 1 Jan 1988 p 44-47.

**095698 CONTINUOUS MONITORING OF GASEOUS CARBON IMPURITIES IN ELECTRONIC-GRADE BULK GASES.** This article first gives a brief overview of current monitoring techniques, and it then describes a new method for monitoring inert-gas purity with respect to CO, CO<sub>2</sub>, and hydrocarbons. The gas-purity monitoring technique described is particularly suitable for continuous monitoring of CO, CO<sub>2</sub>, and hydrocarbons. Since the catalyst has a high methanation activity and low metal and support-surface areas, CO and CO<sub>2</sub> are converted efficiently, with rapid response time achieved due to minimal product retention. This technique will enable semiconductor device manufacturers to record instantaneous variations in inert-gas purity that could not otherwise be monitored, and to do so with greater accuracy and reliability than are now possible. 2 refs.

## Mathematical Models

**095699 EMPIRICAL EVALUATION OF A QUEUEING NETWORK MODEL FOR SEMICONDUCTOR WAFER FABRICATION.** The congestion problems that plague wafer fabrication facilities are described in general terms, and several years' operating data from one particular facility are summarized. A simple queueing network model of that facility is constructed, and the model is used to predict certain key system performance measures. The values predicted by the model are found to be within about 10% of those actually observed. These results suggest that queueing network models can provide useful quantitative guidance to designers of wafer fabrication facilities, and we discuss refinements and extensions of our elementary model that are likely to be important in other settings. An important benefit gained from queueing theory is that congestion and delay in wafer fabrication are caused by variability in the operating environment. (Edited author abstract). 24 refs.

## Process Control

**095700 SPATIALLY RESOLVED ELLIPSOmetry FOR SEMICONDUCTOR PROCESS CONTROL: APPLICATION TO GaInAs MIS STRUCTURES.** A new assessment technique, a spectroscopic ellipsometry system with high lateral resolution (10×10 μm spot), is introduced. Its high surface sensitivity is used at each step of a typical technological process, the fabrication of GaInAs metal-insulator-semiconductor structures, namely oxide removal, etching, and dielectric deposition. The measured nonuniformity of the Si<sub>3</sub>N<sub>4</sub>/GaInAs interface quality over the wafer is directly correlated to the electrical characteristics of the devices. This is a direct proof of the influence of the native oxide at this interface upon the electrical drift of MIS structures. (Author abstract) 19 refs.

## Quartz Applications

**095701 SILICON ON QUARTZ BY SOLID-STATE DIFFUSION BONDING (SSDB) TECHNOLOGY.** Silicon wafer and quartz have been successfully bonded together by a two-step thermal treatment process. SIMS measurements shows that after molecular surface activated solvent treatment, the amount of OH on the silicon or quartz surface, which is essential to the first step (low-temperature) bonding strength, is one order of magnitude higher than that on the original silicon or quartz surface. After a high-temperature (850-1250°C) solid-state diffusion process, the bonding strength between silicon and quartz is increased to 150-185 kg/cm<sup>2</sup>. The material and electrical properties of the silicon on quartz substrate compares favourably with those of the bulk silicon wafer. (Edited author abstract) 4 refs.

**Research** See Also PHOTORESISTS; SEMICONDUCTING SILICON—Ion Implantation.

**095702 MASK FABRICATION BY USING AN ELECTRON BEAM RESIST, CHLOROMETHYLATED POLYSTYRENE, AND DRY ETCHING PROCESS.** The relation between electron beam sensitivity and resolution of chloromethylated polystyrene (CMS) was investigated with respect to molecular weight and dry etching characteristics of chromium thin films in a carbon tetrachloride/oxygen mixed gas plasma in a planar type reactor. The CMS of large molecular weight shows high sensitivity, 0.26 μC/cm<sup>2</sup>, to electron beam exposure and good resistance to dry etching under certain chromium etching conditions. Moreover, detecting the end point of chromium dry etching is possible by measuring the change of electrode voltage during the chromium etching. (Edited author abstract) 15 refs.

**095703 SAPPHIRE - THE LEADING SOI TECHNOLOGY.** Marconi Electronic Devices (MEDL) in association with the GEC Hirst research centre has been carrying out parallel research programmes into SOI technologies for some years. The view from our vantage point is that the only viable SOI technology is Silicon on Sapphire. The reasoning behind this involves the merits of the fabrication process itself; good yields and competitive production costs are not yet available in other SOI techniques. The main considerations are the criteria for radiation resistance evaluated by the US Department of Defense for VHSIC (very high speed integrated circuits). The article is a short report on the new SOS technology products.

**095704 GROWTH AND PROPERTIES OF TIN AND TiO<sub>2</sub>N<sub>x</sub> DIFFUSION BARRIERS IN SILICON ON SAPPHIRE INTEGRATED CIRCUITS.** The usefulness of titanium nitride thin films deposited under

different sputter deposition conditions as a diffusion barrier in silicon-to-aluminum contacts was examined. In particular, the effect of oxygen in the barrier film was investigated. The films were r.f. sputter deposited from a titanium target in an Ar-N<sub>2</sub> or Ar-N<sub>2</sub>-O<sub>2</sub> gas mixture under varying conditions of applied d.c. substrate bias voltage. The variations in film oxygen content, resistivity, film stress and deposition rate are presented as functions of nitrogen and oxygen partial pressures, and applied substrate bias. The diffusion barrier properties of dark brown films (B films) deposited under no-bias conditions, bright golden films (G films) deposited under proper substrate bias, and oxygen-containing golden films (Ox films) were tested by Rutherford backscattering spectrometry and optical measurements at temperatures of 450-600°C. (Edited author abstract) 35 refs.

## United States

**095705 NATIONAL SECURITY AND THE SEMICONDUCTOR INDUSTRY.** Since 1979 the US share of world semiconductor market has been steadily dropping while that of Japan has been rising sharply and has now overtaken the US market share. Implications for the national security of the USA of the international collaboration in chip manufacture are discussed. The efforts made by the Sematech Corporation supported by DOD to recover America's lead in the microelectronics industry are described and evaluated.

**095706 IN-PROCESS WAFER TEST AND MEASUREMENT.** Major investments in equipment development, traditionally directed toward improvements in wafer processing equipment, are increasingly going into development of instrumentation for better ways of monitoring and controlling wafer-processing production. The reasons for this trend are rooted in both economics and technology: Process control is cost-effective because it increases device yields and performance. It also enables semiconductor manufacturers to produce more complex integrated circuits that, in turn, require more process control.

Dey, Jim (Micro Image Techniques, Los Gatos, CA, USA). *Semicond Int* v 11 n 1 Jan 1988 p 52-55.

**095707 RING TESTING OF DISCRETE DEVICES IMPLEMENTING POLYNOMIAL FORMS.** A method for synthesis of systems for diagnostic testing is described. It is based on transformation of a discrete testing object into a follower or an automatic device. The functions of the objects are assumed to be expressed by polynomial forms. Self-testing offers a simple implementation of tests by software and hardware and a compact representation of tests and output responses of the discrete devices (DD) being tested. In addition, on the basis of polynomial forms of DD functions, diagnostic tools of self-testing can be constructed. This approach is used in the present paper. 8 refs.

## Computer Interfaces

**095708 SMD TESTING: UPDATE ON DEVICE HANDLERS AND BOARD FIXTURES.** With surface-mounted devices (SMDs), engineers can design more functions into less space than ever was possible with so-called conventional components. The culmination of this technology is products with improved performance at lower costs. Design for testability is considered that forces the designer and the test engineer, closely working together, to develop a product that, quite simply, can be reliably and efficiently tested.

## Radiation Effects

**095709 DOSIMETRY AND TOTAL DOSE RADIATION TESTING OF GAAS DEVICES.** Damage to GaAs devices from energetic electrons is shown to rise rapidly above 600 keV. Therefore, methods of dosimetry that are more sensitive to low-energy electrons (i.e., that determine deposited energy rather than atomic displacement) could be inappropriate for GaAs. For example, a 1-MeV electron irradiation requires an order-of-magnitude lower dose (in rad) to cause the same degradation as a  $^{60}\text{Co}$  source in a GaAs FET. Such considerations are used by the authors to argue against the use of rad dose to define mission radiation requirements and laboratory source calibration for GaAs devices. 7 refs.

**095711 QUERSCHLIFF-PRAEPARATION VON METALL-ISOLATOR-METALL DUENNSCHICHTKATHODEN FUER DIE HOCHAUFGELOESTE ABBILDUNG MIT DEM TEM.** [Cross-Sectional Preparation of MIM Systems]. Metal insulator metal (MIM) systems of thin layers are of interest in many applications and physical investigations. In this context it is important to dispose of exact statements on the composition of such systems and its change during activity. An important direct method producing such statements is the cross-sectional examination developed in the latest years based on the preparation of thin cross-sections by mechanical polishing and ion milling until the thickness of the central region of the specimens is reduced to electron transparency, and high resolution electron optical imaging becomes possible. We are describing a method of cross-sectional work which we have successfully applied to MIM systems. (Author abstract) In German. 2 refs.

**095712 SPATIAL PIXEL CROSSTALK IN A CHARGE-INJECTION DEVICE.** An optical multichannel detector system based on a charge-injection device (CID) sensor has been designed and constructed. This system is intended for use in a variety of spectroscopic studies, including atomic emission spectrometry (AES), in the ultraviolet to near-infrared spectral region. A General Electric Co. CID11B was selected as the sensor because preliminary research indicated that this device has excellent characteristics for detection of the very wide dynamic range signals encountered in AES. During initial characterization of this detection system, a phenomenon was observed in which the signal obtained from reading a pixel of the array was affected by the quantity of charge in orthogonally located pixels. Investigations indicate that this spatial crosstalk effect is not caused by charge migration among pixels ('blooming') as in many other types of imaging detectors. (Edited author abstract) 19 refs.

Sims, Gary R. (Univ of Arizona, Tucson, AZ, USA); Denton, M. Bonner. *Opt Eng* v 26 n 10 Oct 1987 p 999-1007.

**095713 ENERGY-BAND OFFSET OF  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As-In}_{0.52}(\text{Ga}_{1-x}\text{Al}_x)_2$  48As HETEROSTRUCTURES, DETERMINED BY PHOTOLUMINESCENCE EXCITATION SPECTROSCOPY OF QUASI-PARABOLIC QUANTUM WELLS GROWN BY MBE.** The conduction-band discontinuity,  $\Delta E_c(x)$ , of the heterostructure was determined to be  $(0.73 \pm 0.03)\Delta E_g(x)$  ( $0 \leq x \leq 1$ ), by a comparison of the electron (and hole) energy levels in quasi-parabolic (multi-stepped) quantum wells observed by photoluminescence excitation spectroscopy, with numerical solutions of Schrodinger's equation, with non-parabolicity of the conduction band was considered. (Edited author abstract) 25 refs.

**095714 CAPACITANCE-VOLTAGE CHARACTERISTICS OF P-N JUNCTION OF THE NARROW BAND-GAP SEMICONDUCTORS  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$ .** The measuring technique of capacitance is improved so that the capacitance of P-N junction with low resistance can be made. The measurements of the C-V characteristics of P-N junction of  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  ( $0.195 < x < 0.28$ ) are presented. It is found that the C-V curve of these P-N

junctions has a maximum and some 'negative' values, which can not be explained by the usual mechanism of diffusion capacity and the barrier-layer capacity. In comparing with the theory of indirect tunnelling capacity, these abnormal phenomena can be attributed to the tunnelling process between the deep impurity level and the conduction or/and valance bands. (Author abstract) 7 refs. In Chinese.

**095715 POSITION SENSITIVE DETECTORS USING HYDROGENATED AMORPHOUS SILICON.** Hydrogenated amorphous silicon (a-Si:H) offers some technical advantages over crystalline silicon for optical position sensing devices since it can be grown on a large variety of substrates at approx.  $250^\circ\text{C}$ , over large areas and at lower cost than crystalline Si. Its transparency to red light makes it suitable for applications which require superimposed detectors. We have examined a variety of layered a-Si:H structures using gold or Nichrome resistive contact layers and found that a multiple sequence of n-type/undoped/n-typed thin films offers the best positional linearity and the minimum change by the Staebler-Wronski effect. **095717 IMPLEMENTATION OF A NEW METHOD FOR THERMAL ANALYSIS OF PLANE MULTILAYERED SYSTEMS.** This paper reports the implementation of a new method for temperature calculations in plane multilayered systems. The method involves both analytical and numerical approaches to heat flow analysis and is well suited for power semiconductor systems where plane power dissipation can be assumed. The general case of an N-layered system is presented and some examples of calculations are given. The method, which involves short computation times, is usable on small computer systems and offers an alternative to finite-difference or finite-element methods as long as plane multilayered systems are considered. **095718 FINDING REPLACEMENT SEMICONDUCTORS.** Electricians in modern facilities are adding repair of solid-state devices to their list of responsibilities. Being knowledgeable about the cross-referencing process enables these individuals to purchase replacement devices locally instead of buying original parts from the equipment manufacturer. This keeps downtime to a minimum and usually reduces the cost of the replacement parts. Semiconductors such as diode rectifiers, transistors, silicon-controlled rectifiers, and integrated circuits are used in all types of manufacturing equipment and in all phases of power control. The maintenance electricians must not only know how to test these devices as part of their troubleshooting responsibility, but in many instances they must select replacements for failed devices.

**095724 ADVANCED PROCESSING OF SEMICONDUCTOR DEVICES.** Proceedings incorporates 44 papers that are grouped in five sessions. These deal with frontiers in silicon technologies of rapid thermal annealing (RTA), silicon-on-silicon (SOI), and silicides; plasma, laser and wet chemical processing of semiconductors; ion-beam and high-temperature processing of III-V and II-VI semiconductors; epitaxial regrowth and optoelectronic devices; and high-speed electron device technologies. Topics considered include: heterojunctions; bipolar transistors, FET, GaAs, AlGaAs, MOCVD, resonant tunneling bipolar transistors (RBT) permeable base transistors, high-electron-mobility transistors (HEMT), logic devices, MESFET, MOS capacitors, ternary semiconductors, CdTe films, IR detectors, quantum well lasers, reactive ion etching (RIE), distributed feedback (DFB) lasers; surface emitting semiconductor lasers, optoelectronic IC's, ion implantation, MODFET, superlattices, single crystals, silicon nitride films, and amorphous materials. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11659 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

#### Amorphous

**095725 HYDROGENATED AMORPHOUS SILICON ELECTRONIC DEVICES AND THEIR ARRAYS.** The physics, fundamental limitations, and applications of amorphous devices are discussed. The most attractive application of a-Si:H electronic devices is in an active matrix. Examples are large-area flat-panel displays in portable television sets and video display terminals, as well as large-area contact-type image sensors in facsimile transducers. Current efforts are directed to developing arrays having more than 200×200 pixels. It is already evident that a-Si:H FETs have satisfactory characteristics for such applications, and that the important remaining

problems are to reduce production costs while maintaining long-term stability. An alternative technology, which is based on the polysilicon FET, is competing increasingly with the amorphous device technology. The potential usefulness of a-Si:H devices has been clearly demonstrated, but their practical importance has not been finally established, since further improvement of their performance and fabrication is required. This chapter, therefore, describes both the state-of-the-art technologies and performance of a-Si:H devices, and various technological trends aimed at achieving still further improvement. 63 refs.

**095726 NUMERICAL SIMULATION OF THE DYNAMICS OF FIELD IMPROVISHMENT MODES.** The possibility of low field and reversed step domains in multivalley semiconductors was suggested over 20 years ago by J.A. Copeland and was re-examined more recently by a different method. Both refer only to the possibility stationary domains, which, once formed, propagate along an infinite device. Appropriate initial and cathode conditions are established for GaAs by numerical simulation using Boltzmann's transport equation and assuming constant voltage at the terminals. These conditions may lead to the repeated formation of these domains, giving rise to transmit time modes and seem promising in providing a higher power transfer than traditional ones, because the sign of the bulk charge is reversed while domain velocity and field directions remain opposite to each other. Hot electron launching which is indispensable to the process, might be achieved by suitable heterojunctions, namely at the cathode.  $Al_xGa_{1-x}As/GaAs$  is a possibility. **095728 EIGENSTATE CALCULATION OF QUANTUM WELL STRUCTURES USING FINITE ELEMENTS.** The finite-element technique based on a Galerkin method is applied to the eigenstate problem of semiconductor quantum wells with arbitrary potential profiles. In the present formulation, finite elements are employed only within the well region, and the contribution of the semi-infinite barrier region is evaluated analytically. Self-consistent solutions are obtainable by solving a matrix eigenvalue problem iteratively. (Author abstract) 4 refs.

**095729 IMPORTANCE OF THE N-BASE IN P-N-P-N-LIKE STRUCTURES SUBJECTED TO DV/DT RAMPS.** A simple yet thorough analysis of physical effects induced in p-n-p-n-like silicon structures by the high rate of the OFF-state forward anode voltage rise (dV/dt) is discussed. The importance of n-base parameters in shaping the faulty triggering of thyristors subjected to dV/dt ramps is clearly demonstrated. The main implications of the findings for thyristor physics and design are also outlined. 8 refs.

**095730 SINGLE-ELEMENT CHARGE-INJECTION DEVICE AS A SPECTROSCOPIC DETECTOR.** The need for a single-element charge-transfer device as a spectroscopic detector is discussed. Such a detector promises to offer superior performance compared to current photomultiplier tubes over a wide range of illumination levels. As a detector to address this need, the prototype CID75 manufactured by General Electric Co. is described and characterized. The CID75 is a single-element charge-injection-device sensor with a 1 mm by 1 mm photoactive area and a readout rate adjustable from 0 to 20 kHz. The electro-optical characteristics reported in this study include linearity, read noise, full-well capacity, dark count rate, and quantum efficiency. The sensors have good photometric linearity with a full-well capacity in excess of  $1.2 \times 10^8 e^-$ . The read noise of the detector can be lowered to  $80 e^-$  when its nondestructive readout mode is employed. The quantum efficiency of the CID75 is reported for the wavelength range from 200 to 1000 nm. (Edited author abstract) 27 refs.

**095731 SYSTEMS APPLICATIONS OF GaAs DEVICES AND ICS.** Gallium arsenide (GaAs) is now being considered by the semiconductor industry as a serious challenger to the dominance of silicon in high-speed digital circuits. In addition, with the accelerated progress in developing GaAs ICs for microwave and optoelectronics applications, major future markets are projected. This paper surveys the product areas and associated system applications for GaAs and related III-V compound semiconductor devices and ICs. Particular attention is given to the three main IC product areas of digital, analogue and optoelectronics and their applications to both military and civil systems. The strongest market currently is for military analogue devices. The projected digital market in the 1990s, however, dominates the other IC product areas. (Author abstract) 7 refs.

**095734 THEORETISCHE UND EXPERIMENTELLE UNTERSUCHUNG EINES NEUARTIGEN GaAs-MeSFET-FREQUENZVERDOPPLERS.** [Theoretical and Experimental Characterization of a Novel GaAs-MeSFET Frequency Doubler]. GaAs-MeSFETs with large gatewidth ( $W = 1000 \mu m$ ) and connecting pads at both ends of the gate and drain electrodes were fabricated. A maximum doubler output power of 10 dBm was obtained under optimum bias and circuit conditions. Theoretical analysis of the frequency doubler as a four-port device using generalized Volterra series approach predicted well the output power/input power and output power versus reflection coefficients characteristics. The influence of the distinct parameters of the doubler is outlined. (Edited author abstract) In German. 7 refs.

**095735 EFFICIENT SMOOTHING ALGORITHM FOR SPREADING RESISTANCE CALCULATIONS.** The need for a good smoothing algorithm before applying a more elaborate correction algorithm to spreading resistance data is illustrated. The important requirements for such a scheme are formulated. A new efficient smoothing scheme has been implemented and tested. It is shown that this scheme substantially improves the generated carrier concentration profiles and makes their interpretation easier. (Author abstract) 16 refs.

**095736 SENSITIVITY ANALYSIS FOR DEVICE DESIGN.** A sensitivity analysis technique for device design is proposed. By this method, the linearized variations of the device terminal characteristics are derived following some change either in the impurity distribution, or in device geometry, such as channel length an oxide thickness. This technique has been implemented in a general-purpose two-dimensional device-analysis program, and proved to be very efficient. It is believed that the present method can be profitably used for both deterministic and statistical device design. 20 refs.

**095738 SUPERVISED SIMULATION SYSTEM FOR PROCESS AND DEVICE DESIGNS BASED ON A GEOMETRICAL DATA INTERFACE.** A supervised simulation system for two-dimensional simulation has been developed that covers the range from pattern layout to process and device simulation. The major aim is to provide a topography data format that allows automatic data treatment between topography simulation and implantation-diffusion simulation, and also between process and device simulation. Another important feature is job and file management by the system controller, which controls the module programs. Using a novel data format, the total fabrication process (deposition, etching, reflow, implantation, diffusion including oxidation) and device simulation is automatically completed by the system controller without any intricate treatment. 20 refs.

**095740 COMPREHENSIVE TRANSPORT MODEL FOR SEMICONDUCTOR DEVICE SIMULATION.** In this paper a comprehensive carrier dynamical transport model for semiconductor device simulation is presented. The model consists of carrier, carrier momentum and carrier energy conservation relations derived using a perturbation solution for the carrier distribution function. Carrier degeneracy, multiple conduction sub-bands and ellipsoidal constant energy surfaces are accounted for, and the effective masses and band edges are assumed to be spatially inhomogeneous. The new formulation overcomes modelling inaccuracies of previous energy transport models based on a drifted Maxwellian distribution function, and for spatially homogeneous, non-degenerate semiconductors offers several computational advantages. (Author abstract) 14 refs.

**095741 INTERCHANGE FORMAT FOR PROCESS AND DEVICE SIMULATION.** A standard format for transmitting profiles of semiconductor structures between sites and between tools is described. The standard, called the profile interchange format (PIF), is a flexible and hierarchical format, capable of storing descriptions of semiconductor structures such as those produced and used by process and device simulators. It can store detailed descriptions of the geometry, attribute profiles, material properties, and transient behavior of a single structure or a collection of structures. Two equivalent forms of the PIF are proposed to resolve conflicting demands placed on the format by its two primary uses, which are transmitting profiles between sites and local use as a database for process and device simulation. The 'intersite' form of the PIF, which can be viewed as an

extension of the electronic design interchange between sites, most importantly, portability. The 'intertool' form of the PIF is, in concept, equivalent in descriptive capabilities to the intersite form, but is intended to accommodate the needs of profile interchange between tools, most importantly, efficient storage and access of data. The PIF in both modes can be extended and modified to accommodate local needs. 10 refs.

**095742 RECENT APPLICATIONS OF MONTE CARLO METHODS FOR SEMICONDUCTOR MICRODEVICE SIMULATION.** Monte Carlo simulations for semiconductor devices are time consuming. We have investigated ways to speed up calculations on supercomputers and a method to incorporate overshoot effects in simple drift-diffusion models for submicron devices, using coefficients obtained from Monte Carlo experiments. An ensemble Monte Carlo algorithm, suitable for self-consistent device simulation, has been vectorized, and in preliminary testing runs three times faster on a CRAY X/MP 48 supercomputer. The inclusion of overshoot terms in a drift-diffusion simulation for a MESFET structure shows that the main overshoot effects can be incorporated in a simple model suitable for circuit simulation. Increased problems in stability, however, reduce the efficiency of traditional finite difference schemes and require further refinement in the numerical methods. (Edited author abstract) 10 refs.

**095743 PRELIMINARY STUDIES OF Al-Ge-Ni OHMIC CONTACTS TO p- AND n-TYPE GaAs.** The authors have performed electrical measurements (I-V characteristics) and transmission electron microscopy (TEM) investigations of the contact with the aim of correlating contact microstructure with electrical behavior to understand the contact and optimize its performance. It is found that all Al-Ge-Ni contacts to p-type GaAs were found to be ohmic, whereas only 3 and 4 minute annealed contacts on n-type material were ohmic. There is a large difference in microstructure between contacts on n- and p-type material, suggesting this may be affected by the nature of the semiconductor. In spite of this, contact ohmicity appears to be accompanied by the presence of a well developed amorphous layer with a web-like structure consisting mainly of Al and some Ni. 2 refs.

**095744 DEGRADATION OF THE Mg/SiO<sub>2</sub>/p-Si CONTACT.** Magnesium is a widely-used contact metal in semiconductor device applications, especially in high-efficiency silicon solar cell investigations. P-type float-zone wafers were used in this study. We have shown that the degradation of the Mg/SiO<sub>2</sub>/p-Si contact is governed by a low activation energy of 1.64 eV and the main cause for degradation is saturation current degradation. Extrapolation of the Arrhenius plot indicated that the degradation rate is still negligible at low temperature. 5 refs.

Poon, M.C. (Chinese Univ of Hong Kong, Hong Kong). *J Mater Sci Lett* v 6 n 12 Dec 1987 p 1377-1378.

**095745 FORMATION OF OHMIC CONTACTS TO n-GaAs BY ION BEAM MIXING AND ANNEALING.**

A study carried out by the authors has shown that by using ion beam mixing on the Au-Ge/Ni/GaAs system, followed by an annealing step, an ohmic contact to n-GaAs can be formed. The morphology of the contacts fabricated in this way was better than the contacts without the ion implantation step. From Auger depth profiles, it follows that a region of uniformly mixed nickel/germanium/arsenic system formed, which spread uniformly throughout the metallization layer. In contrast, contacts which were only annealed exhibited regions of non-uniformly mixed Ni and Ge and of Ni and As. An Auger study revealed that more Ni diffused into the GaAs for the ion implanted contacts, and this helps to trap more Ge in the substrate, which is beneficial for doping purposes. (Edited author abstract) 20 refs.

Barnard, W.O. (CSIR, Pretoria, S Afr); Malherbe, J.B.; Lacquet, B.M. *Appl Surf Sci* (1985) v 31 n 4 May 1988 p 437-444.

**095746 RAPID THERMAL ANNEALING OF Al-Si CONTACTS.** A simple and direct method by utilizing rapid thermal annealing for 30 sec of conventional furnace instead of conventional sintering, is reported. AES, SEM, specific contact resistance and PN junction reverse current investigations show that Al-Si interdiffusion phenomenon which causes the failure for shallow junctions can be restricted effectively; therefore ohmic contact with good junction property can be achieved. (Edited author abstract) In Chinese. 11 refs.

Chen Cunli (Nanjing Univ, China); Peng Hui; Li Lianzhu. *Pan Tao Ti Hsueh Pao* v 9 n 3 May 1988 p 318-320.

**095747 CONTACT RESISTANCE CALCULATIONS BASED ON A VARIATIONAL METHOD.** Noble's variational method is used to solve the contact resistance problem that arises when a circular disc source electrode is in contact with a semiconductor slab through an infinitesimally thin layer of resistive material. The method assumes that the source current density distribution  $J(r)$  has the form  $K_1(1-r^2) - \mu + K_2(1-r^2)^{3/2} + K_3(1-r^2)^{3/2}$ , where the parameters  $K_1$ ,  $K_2$ ,  $K_3$  and  $\mu$  are determined by variational principles. Calculations of the source current density and the total slab resistance, performed for a wide range of contact resistivities, show that the results are practically indistinguishable from those derived from an exact mixed boundary value method proposed earlier by us. While this method of using an optimized  $\mu$  is accurate, it is computationally slow. By fixing  $\mu$  at a constant value of 1/4, the authors find that they can reduce the computation time for each calculation of the total slab resistance to 1.5 s on an Apple II microcomputer, and still achieve an overall accuracy of 1%. Tables of the abscissas and weights required for implementation of the numerical scheme are provided. (Edited author abstract) 13 refs.

Leong, M.S. (Natl Univ of Singapore, Kent Ridge, Singapore); Choo, S.C.; Tan, L.S.; Goh, T.L. *Solid State Electron* v 31 n 7 Jul 1988 p 1187-1195.

**095748 COMBINED EBIC-AUGER ANALYSIS OF AuGeNi/ n-GaAs OHMIC CONTACT FORMATION.** Electron beam induced current imaging has been used to monitor the dynamic changes of the metal-semiconductor interface of AuGeNi/n-GaAs during annealing at 300°C. The reacted interface was then revealed by argon ion etching of the metal overlayer, and analyzed by secondary electron and Auger electron imaging. The combined EBIC-Auger imaging of the reacted interface indicates that the formation of the ohmic contact starts at localized areas where small Ni- and As-rich grains are formed. The results also show that this combined EBIC-Auger imaging technique is particularly suitable for investigating the mechanism of degradation of Schottky contacts. (Author abstract) 7 refs.

**Contamination** See Also SEMICONDUCTING SILICON COMPOUNDS—Cleaning.

**095749 HEAVY METAL CONTAMINATION FROM RESISTS DURING PLASMA STRIPPING.** A new mode of heavy metal contamination has been investigated. Generally used commercial positive photoresists containing heavy metal less than 0.5 ppm decreased minority carrier lifetime of the silicon substrate under the resist layer during resist stripping with a plasma asher. Since this contamination is induced by direct plasma exposure, it can be avoided by using plasmaless resist removal methods, such as wet stripping or down flow ashing. However, even in such resist stripping methods, a wafer temperature higher than 300°C introduces this problem. This contamination is reduced by both covering the silicon surface with a silicon oxide layer and by purifying the resists. Neither of these methods are perfect. (Author abstract) 20 refs.

**Corrosion** See Also INTEGRATED CIRCUITS—Corrosion.

**095750 SCANNING ELECTRON MICROSCOPY IN THE STUDY OF CORROSION ON ALUMINIZED SEMICONDUCTOR DEVICES.** A study of the influence of the structural quality of the original Al film and the purity of chemical reagents used on the surface film morphology, using a scanning electron microscope, has established that the color change observed when aluminumized surfaces are etched is associated with the presence of heavy-metal impurities (Fe, Ni, Cr, Co and Zn ions). If the Al film structure is defective, excessive concentrations of these ions promote corrosion and the devices will fail in service. Blackening or coloration occurs when the defective areas are etched with contaminated agents. The heavy-metal ions produce localized electrochemical potential peaks; corrosion is locally accelerated because of the large difference between the work functions of Al and the impurities. Ways are proposed for minimizing the damage to Al-coated semiconductor devices. (Edited author abstract) 9 refs.

**095751 MULTIPLICATION OF DEFECTS IN SEMICONDUCTORS DURING MULTIPLE PASSAGE OF SHOCK WAVES.** Investigations were conducted into the relationships governing the pile-up of point defects in crystals in multiple passage of nondestructive shock waves with a short leading edge. The probability and coefficient of multiplication of defects are determined. In the case of formation of defects of the same type (inherent defects), it is shown that the measurements of electrical conductivity, the life of current carriers, and their mobility can be used to determine the concentration of defects, the coefficients of multiplication of defects on the inherent defects and solutes, and the energy level of defects and their contribution to scattering of the charge carriers. (Author abstract) 8 refs.

**095752 VERIFICATION OF ANALYTIC POINT DEFECT MODELS USING SUPREM-IV.** Two-dimensional process modeling has been complicated by the increasing complexity of the physical models needed to characterize modern processes. Present physical models for diffusion favor modeling of both the vacancies and interstitials as well as the dopant impurities. These vacancies and interstitials are important in two dimensions since the lateral characteristic lengths are on the order of a few microns, which is comparable to device

dimensions. Hence, full two-dimensional solutions of the point defect equations are required to accurately model two-dimensional diffusion. Since the defects diffuse many orders of magnitude faster than the impurities, the problem of solving the coupled equations is numerically stiff and the numerical techniques become critical. The numerical methods in SUPREM-IV are described. Since the numerical solutions are time consuming, suitable analytic solutions are considered as an alternative. These analytic solutions are compared to the numerical results to test the limits of the assumptions used in the analytic formulation. The comparison forces the conclusion that analytic solutions are of limited use in prediction of point defect profiles in two dimensions. 18 refs.

**095753 X-RAY TOPOGRAPHY AND TRANSMISSION ELECTRON MICROSCOPY APPLIED TO SEMICONDUCTOR DEVICE DEFECTS ARISING DURING MANUFACTURE.** When single-crystal silicon devices are being made, dislocations may arise from slip, point-defect condensation, stress relaxation around the impurity clumps, and tensile-stress relaxation at the edges of windows in the silicon oxide. The main purpose of these studies has been to determine whether there is a correlation between these manufacturing defects on the one hand and the electrical parameters of the transistors on the other. Two types of experiment have been performed: 1) X-ray topography applied during the manufacture of epitaxial planar transistors and 2) emitter injection-coefficient measurement for bipolar transistors in relation to defects detected by transmission electron microscopy. The main results are: 1) low dope concentrations in the emitter region produce a structure free from defects with a very high emitter injection coefficient; and 2) an increase in dope concentration causes defects to form in the emitter region, which in turn reduces the injection coefficient. 5 refs.

**Design** See Also SEMICONDUCTOR DEVICES, MOSFET—Fabrication; SEMICONDUCTOR DEVICES, MOSFET—Simulation.

**095754 STRUCTURAL SYNTHESIS OF SEMICONDUCTOR DEVICES.** Our aim here is to find and formulate an algorithm for generating fundamentally new semiconductor devices. The knowledge about the device is represented in the form of three information arrays that contain information about the physical properties of the layers of material. This knowledge is formulated as a graph of the discrete computational environment (DCE). It is shown that any known devices may be obtained from the DCE with the aid of formal procedures. The concepts of an operator and an objective function are introduced. The problem of structural synthesis is formulated as an integral combinatorial problem. A generation algorithm is given. (Author abstract) 4 refs.

**095755 CHARGE WAVEFORM OF A NEW TWO-DIMENSIONAL POSITION-SENSITIVE SILICON DETECTOR.** The operation principles of the two-dimensional position-sensitive silicon detector newly developed by T. Doka et al. were studied using a simple model. This model treats the detector as an area of continuously distributed capacitance  $C$  and resistance  $R_s$  of position surface layer. A linear relationship can then be obtained between the position of the incident particle and charge collected at the corner contacts of the detector. The kinetics of charge collected at corner contacts, ballistic deficit and noise were calculated. Rise time of the charge pulse (10-90 percent) was found to vary with the position of incidence up to about  $R_s C/8$ . It was found that a shaping time constant longer than  $R_s C/3$  is required for

pulse shaping with single CR-differentiation and single CR-integration in order to obtain a ballistic deficit of less than 1 percent. (Author abstract). 14 Refs.

**095756 POWER SEMICONDUCTOR DEVICES: AN OVERVIEW.** Advances in power semiconductor devices are discussed, focusing on the adaptation of silicon integrated circuit wafer processing methods to the design and fabrication of power devices. Some basic properties of power devices are reviewed, along with recent adaptations of wafer processing technology. Two trends are discerned: increasing use of self-aligned, double diffused MOS gate structures to achieve devices with low-current drive requirements; and movement toward an ideal one-dimensional device, thereby making more efficient use of the available area. Different devices are compared: Techniques that have potential for use in power devices are discussed: use of trenches, direct wafer bonding, cellular bipolar transistors, and junction termination. The combination of power switches with control logic on the same chip is briefly considered. 33 refs.

## Electric Conductivity

**095757 DEVICE FOR MEASUREMENT OF RESISTANCE OF SEMICONDUCTORS IN HEATING ELECTRIC FIELDS.** A device for measurement of the resistance of low-resistance semiconductors in heating electric fields is described. To simplify calculation of carrier mobility, an analog device is used to measure resistance for a fixed input power of up to 15 w. The device measures resistance in the temperature range of 77-300 K and magnetic-field range of 0-8 T. (Author abstract) 6 refs.

Loshkarev, V.V. *Instrum Exp Tech* v 30 n 4 pt 2 Jul-Aug 1987 p 975-977.

**095758 QUICK MEASUREMENT OF NONLINEAR CONDUCTION WITH A SINGLE PULSED FIELD.** A method of quickly measuring the nonlinear conduction of a semiconductor is developed where a single triangular pulsed field is used. The warm electron coefficient larger than  $4 \times 10^{-7} \text{ cm}^{-2}/\text{V}^2$  can be measured when it is well defined up to a sufficiently high field, for instance approx. 20 V/cm. Field dependence of the conductivity of pure InSb is measured at 50 and 63, where the nonlinear signal is small and the dependence is complicated. (Author abstract). 4 Refs.

**095759 TWO-DIMENSIONAL NUMERICAL ANALYSIS OF ELECTRIC FIELD PROFILE FOR HIGH VOLTAGE SEMICONDUCTOR DEVICES.** A two-dimensional numerical analysis of electric field profile for high-voltage devices using a computer simulation program is presented. The program is based on a finite element method. A simple empirical formula for calculation of surface electric field in an abrupt planar junction is derived and compared with the cylindrical approximation and simulation results. Electric field profiles are also given for high-voltage devices with terminal structure of ion implantation, plate and extension of gate. (Edited author abstract) In Chinese. 10 refs.

**095760 EFFECT OF REFLECTING CONTACTS ON HIGH FIELD TRANSPORT.** There has been

interest in semiconductor device structures which take advantage of high velocity, high field transport. The high electron velocity in devices that take advantage of such transport is degraded if electrons are reflected at collecting contacts. This was demonstrated quantitatively by Brennan and coworkers (1983) who modeled the collecting contact with a constant, arbitrary reflection coefficient. For a real contact, however, the probability of an electron being reflected depends on its energy and momentum. We present a study of the effect of contacts on high field transport by Monte Carlo simulations of transport in an  $n^-$  GaAs region which terminates in an  $n^+$  GaAs/metal contact (Arnold 1987). (Edited author abstract) 4 refs.

**095761 USE OF A COMPUTER SIMULATION TO INVESTIGATE THE INFLUENCE OF NONLINEAR PHYSICAL EFFECTS OF THE CURRENT-VOLTAGE CHARACTERISTIC OF SILICON MULTILAYER STRUCTURES.** The results of a mathematical computer simulation to investigate the influence of electron-hold scattering (EHS), Auger recombination, and the reduction of the kinetic coefficients and Shockley-Read lifetime of charge carriers in the heavily doped layers on the forward branch (FB) of the current-voltage characteristics (CVC) of multilayer silicon structures are presented. A numerical model of the CVC is constructed, in which the contribution of the above effects is taken into account for the first time. It is shown that the incorrect consideration of EHS in previous papers has led to an exaggerated contribution from EHS and, as a consequence of this, to a decrease in the contribution of the other effects. (Author abstract) 18 refs.

**095762 RESONANT TUNNELING DEVICE WITH MULTIPLE NEGATIVE DIFFERENTIAL RESISTANCE: DIGITAL AND SIGNAL PROCESSING APPLICATIONS WITH REDUCED CIRCUIT COMPLEXITY.** A novel way to obtain multiple peaks in the current-voltage characteristic of a resonant-tunneling (RT) device is demonstrated. The peaks are generated using only the ground-state resonance of the quantum well rather than several states, as in conventional RT devices. The separation between the peaks is voltage-tunable, and the peak currents can be made nearly equal, which is necessary to use the device in a variety of circuit applications. A functional device operating at 100 K with two peaks in the I-V has been fabricated. The first practical demonstration of circuits for frequency multiplication by a factor of five, a three-state memory and a 4-b parity generator using a single functional RT device each, is also reported. The use of multiple-peak RT devices in these circuits results in an order-of-magnitude reduction in the number of components per function over conventional techniques. 18 refs.

**095763 RANDOM QUANTUM INTERFERENCE IN MICRODEVICES.** The conductance of small electronic devices at low temperatures is affected by random quantum interference of a universal character that can represent large fractional effects. Would-be designers of small quantum-effect devices should be prepared either to 'fix it' by obtaining unprecedented control over the

microscopic details of the device structure, or 'feature it' by figuring out ways to take advantage of these interference effects. (Edited author abstract) 30 refs.

## Electrochemistry

**095764 MODULATED LIGHT STUDIES OF THE ELECTROCHEMISTRY OF SEMICONDUCTORS: THEORY AND EXPERIMENT.** The photoelectrochemistry of three different semiconductors, p-GaP, n-CdS, and p-InP has been studied using a sinusoidally modulated light source. The results obtained for the resulting modulated photocurrent agree well with a theoretical model based upon surface reactions governed by dispersed rate constants arising from a gaussian distribution of free energies at the electrode solution interface. The technique gives information about the amount of surface recombination occurring as well as values of the rate constants and the surface coverage of intermediates. (Author abstract) 12 refs.

**095765 ON ELECTRON CONFINEMENT EFFECTS AND THE ULTIMATE SIZE REDUCTION IN SEMICONDUCTOR DEVICES.** Three-dimensional electron confinements cause a blue shift of the fundamental band gap and a size-induced metal-insulator transition. These quantum-size effects are expected in confinements with diameters up to the order of 10 and 100 nm at room temperature, in metals and semiconductors, respectively. The size effect can markedly be enhanced by an additional phonon confinement which is omnipresent in isolated sub-micrometer crystals. Confinement effects represent the limitation for the ultra-large-scale integration. (Author abstract) 8 refs.

**095766 INVERSION DOMAINS AND DENSITIES OF STATES IN GAPLESS SEMICONDUCTORS IN A QUANTISING MAGNETIC FIELD.** Gapless semiconductors with the linear electron spectrum are considered taking into account a quantising magnetic field. Deformation potential interactions with phonons are shown to induce the spontaneous destruction of the zero-gap state due to the lowering of the effective space dimension in the magnetic field. The interaction with impurities is shown to shift the band inversion point. The Bogoliubov-de Gennes equations are derived; their inhomogeneous solutions are kinks linking the normal and inverted band domains. The electronic densities of states for two- and three-dimensional zero-gap states in a magnetic field are exactly calculated taking into account the Gaussian random potential and their singularities in the vicinity of band crossing points are studied. Possible consequences of these results for experiments with narrow-gap semiconductors near the inversion point are discussed. (Author abstract) 28 refs.

**095768 MESOSCOPIC COHERENCE PHENOMENA IN SEMICONDUCTOR DEVICES.** Semiconductor devices have several attractive properties which make them useful in the study of electronic coherence phenomena such as universal conductance fluctuations. The use of gated devices allows the Fermi level, and thus the electronic wavelength, to be adjusted in order to study energy correlation effects. The two-dimensional electron gas formed beneath the gate can be tilted with respect to the magnetic field to reveal that the field correlation length of the fluctuations obeys a cosine law. This suggests that the fluctuations are caused by quantum interference in the same way that the Aharonov-Bohm effect arises in metallic rings. The energy range over which electrons are correlated in these materials is generally larger than in metals. This allows one to study these conductance fluctuations at much higher temperatures than are feasible in metallic conductors. For the same reason, larger source-drain voltages can be applied to observe asymmetry and nonlinear effects in the conductance. (Edited author abstract) 57 Refs.

**095769 ANALYSIS OF ELECTRON WAVE REFLECTIVITY AND LEAKAGE CURRENT OF MULTI-QUANTUM BARRIER: MQB.** In this paper, a multi-quantum barrier (MQB) made of super lattices is proposed. First, as a measure for indicating a possibility of improving the efficiency of carrier confinement by an MQB structure, the electron wave reflectivity for the electron energy in such a structure is derived. Next, the leakage current transmitted through the MQB is calculated. By such calculations, it is demonstrated theoretically that the height of the effective potential barrier can be increased from that of a classical barrier. 10 Refs.

**095770 NEW PROFILE OF ULTRA LOW STRESS RESIN ENCAPSULANTS FOR LARGE CHIP SEMICONDUCTOR DEVICES.** Internal stress, as a result of temperature cycle testing (TCT), causes package cracking, passivation film cracking, aluminum pattern deformation, etc. To reduce the internal stress, the authors previously (1987) determined that it is effective to introduce small silicone domains into the epoxy matrix and to create a strong interaction layer between the domain/matrix interface in a heterogeneous structure where soft polymer particles are dispersed as domains in the epoxy matrix as a continuous phase. To date, research efforts have yielded epoxy resins having about 0.1-μm domains with a strong interaction layer at the domain/matrix interface using special silicone modifiers. Comparisons were made between silicone-modified epoxy resins having 2.5-μm domains and smooth domain/matrix interfaces with versions having 0.1-μm domains. 6 refs.

**095771 EFFECT OF POTENTIAL FIELD ON ION DEFLECTION AND SHAPE EVOLUTION OF TRENCHES DURING PLASMA-ASSISTED ETCHING.** A mathematical model was developed to study shape evolution of trenches during plasma-assisted etch-

ing. A two-region sheath model was used to determine the effect of local potential distribution on ion deflection and on the ion flux and energy distribution along the walls of the trench. The potential field in the near-trench region was found by using the boundary integral method which, coupled with a moving boundary scheme, allowed the time evolution of etch profiles to be computed. The effect of important variables affecting ion deflection and sidewall etching was combined in a dimensionless group  $\Omega$ . For values of  $\Omega \leq 0.1$  and for positive mask potentials, less than 10% of the bombarding ion flux struck the sidewall of a rectangular trench. (Edited author abstract) 25 refs.

**095773 ON THE FACTORS IMPAIRING THE COMPOSITIONAL TRANSITION ABRUPTNESS IN HETEROJUNCTIONS GROWN BY VAPOUR-PHASE EPITAXY.** The compositional transition abruptness in a heterojunction is impaired by after-supply of reactants adsorbed at certain surfaces or stored in various types of stagnant volumes (for the case of 'turn-off'). These volumes are found near valves, in vortices and in the boundary layer on the substrate. Expressions are derived for the shapes of the composition profiles to be expected from each of these factors separately, both after turn-off and after turn-on. These make it possible to estimate which factor is dominant and to suggest measures for improvement. In our growth apparatus, modification of the valves and reduction of the entry vortex in the reactor (by using a vertical 'chimney reactor' with bottom inlet) have led to very considerable improvements. (Author abstract) 15 refs.

van Oordorp, C. (Philips Research Lab, Eindhoven, Neth); Leys, M.R. *J Cryst Growth* v 84 n 2 Aug 1987 p 271-288.

**095774 ELECTRON TRANSPORT OF (Al, Ga)Sb/InAs HETEROJUNCTIONS PREPARED BY MOLECULAR BEAM EPITAXY.** Molecular beam epitaxial growth of (Al, Ga)Sb/InAs heterostructures is described. Electron transport studies indicate that these heterojunctions are of high quality. Shubnikov-de Haas measurement of the AlSb/InAs/GaSb quantum well shows a two-dimensional electron gas of concentration  $2 \times 10^{12} \text{ cm}^{-2}$  and a low-temperature mobility approaching  $10^5 \text{ cm}^2/\text{Vs}$ . Low-temperature capacitance/voltage measurement indicates that the thin AlSb barrier is a classical Mott-type barrier. (Author abstract) 8 refs.

Chiu, T.H. (AT&T, Holmdel, NJ, USA); Tsang, W.T.; Levi, A.F.J. *Electron Lett* v 23 n 17 Aug 13 1987 p 917-919.

**095775 ELECTROLUMINESCENT PARAMETERS OF ZnTe-InP HETEROJUNCTIONS.** We made zinc telluride-indium phosphide heterojunctions by epitaxial deposition of ZnTe in a quasiclosed volume on variously oriented InP substrates; film thicknesses about 100  $\mu\text{m}$ . We examined the electroluminescence (EL) spectra of the p-ZnTe-n-InP junctions with direct current up to  $1 \text{ A}\cdot\text{cm}^{-2}$  and in pulsed mode up to about  $10^2 \text{ A}\cdot\text{cm}^{-2}$ . The measurements were made at 77 and 300°K with forward and reverse bias. These heterojunctions emit in the green region, with quantum yields higher by two orders of magnitude than those obtained previously with other structures of  $\text{A}^{\text{III}}\text{B}^{\text{V}}\text{-A}^{\text{II}}\text{B}^{\text{V}}$  type. 14 refs.

**095776 CYCLOTRON RESONANCE INVESTIGATIONS IN GaInAs(P)/InP HETEROJUNCTIONS GROWN BY LOW-PRESSURE METAL-ORGANIC CHEMICAL VAPOUR DEPOSITION.** We report in this letter the study of the cyclotron resonance spectrum of a two-dimensional electron gas at the  $\text{Ga}_{0.47}\text{In}_{0.53}\text{As}/\text{InP}$  interface, grown by low-pressure metal-organic chemical vapor deposition. Quantum oscillations that are clear consequences of the two dimensionality of the system have been evidenced in the region of cyclotron resonance. By tilting the sample, a second absorption peak added to the normal cyclotron resonance has been observed; it has been connected with the fact that two electric sub-bands were occupied at the heterojunction. (Author abstract) 16 refs.

**095780 ON A TWO-DIMENSIONAL ELECTRON GAS MODULATED BY A PERIODIC POTENTIAL.** After a brief introduction to the semiconductor heterojunction devices in which a two-dimensional electron gas can be realized and can be subjected to a periodic potential through a grating, the linear response function for this periodically modulated system is calculated in the random-phase approximation. Two solvable models have been considered, based on the anisotropic electron kinematics arising from the periodic potential. For the first model, approximate and exact results are obtained when (the Fermi level)  $E_F > 2t$  (half the band width) while, for the second model, exact results are obtained when  $E_F > 2t$  as well as  $E_F < 2t$ . Results for the static polarizability and the plasmon dispersion are explicitly displayed. (Author abstract) 16 refs.

**095781 OPTICAL LIMITATION IN A SYMMETRICAL PbS/PbSSe/PbSnSe HETEROSTRUCTURE.** A comparative analysis is performed of the waveguide properties of PbS/PbSSe/PbSnSe twin heterostructures with separate electron and optical limitation and PbSSe/PbSnSe twin heterostructures. It is shown that a reduction in the generation limit of lasers based on the twin heterostructures with separate electronic and optical limitation is caused by the optical limitation which is more effective than in the twin heterostructure. (Author abstract) 5 refs.

Selivanov, Yu.G.; Shotov, A.P. *Sov Phys Lebedev Inst Rep* n 4 1987 p 33-37.

**095782 TEMPERATURE DEPENDENCE OF THE MOBILITY IN HETEROSTRUCTURES MODIFIED BY MULTI-SUBBAND EFFECTS.** Recent experimental studies of the temperature dependence of the electron

mobility for GaAs-GaAlAs heterostructures in the low temperature range have been reported. The authors observed both an increase and a decrease of the mobility (or, equivalently, of the normalized resistance) with increasing temperature in dependence on several sample parameters. This behavior is explained by an interplay between scattering due to ionized impurities (positive temperature dependence) and acoustic phonons (negative temperature dependence). It is shown that intersubband scattering can significantly influence the temperature dependence of the mobility in heterostructures. 7 refs.

**095784 CLOSED-FORM METHOD FOR SOLVING THE STEADY-STATE GENERALIZED ENERGY-MOMENTUM CONSERVATION EQUATIONS.** The Boltzmann transport equation applied to electron transport in a heterostructure semiconductor is discussed. The closed-form methods for solving the heterostructure energy-momentum conservation equations are considered and the energy flux conservation equation is suggested as an additional equation to be solved in the hydrodynamic hot electron transport model. Suitable numeric stable discretization schemes for the conservation equations are presented. (Author abstract) 13 refs.

Azoff, E.M. (Rutherford Appleton Lab, Didcot, Engl). *COMPEL Int J Comput Math Electr Electron Eng* v 6 n 1 Mar 1987 p 25-30.

**095785 EFFECT OF SURFACE ENCAPSULATION AND  $\text{As}_4$  OVERPRESSURE ON Si DIFFUSION AND IMPURITY-INDUCED LAYER DISORDERING IN GaAs,  $\text{Al}_x\text{Ga}_{1-x}\text{As}$ , AND  $\text{Al}_x\text{Ga}_{1-x}\text{As-GaAs}$  QUANTUM WELL.** Data are presented demonstrating that the surface encapsulant and the  $\text{As}_4$  overpressure strongly affect Si diffusion in GaAs and  $\text{Al}_x\text{Ga}_{1-x}\text{As}$ , and thus are important parameters in impurity-induced layer disordering. Increasing  $\text{As}_4$  overpressure results in an increase in diffusion depth in the case of GaAs, and a decrease in diffusion depth for  $\text{Al}_x\text{Ga}_{1-x}\text{As}$ . In addition, the band-edge excitation is observed in absorption on an  $\text{Al}_x\text{Ga}_{1-x}\text{As-GaAs}$  superlattice that is diffused with Si and is converted to bulk crystal  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  via impurity-induced layer disordering. In contrast, the excitation is not observed in absorption on GaAs diffused with Si in spite of the high degree of compensation. These data indicate that the Si diffusion process, and the properties of the diffused material, are different for GaAs and for  $\text{Al}_x\text{Ga}_{1-x}\text{As-GaAs}$  superlattices converted into uniform  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  ( $0 \leq x \leq 1$ ) via impurity-induced layer disordering with the amphoteric dopant Si. 12 refs.

**095786 ELECTRICAL PROPERTIES OF INTERFACIAL TRAPS IN SELECTIVELY DOPED AlGaAs/GaAs HETEROSTRUCTURES.** A hole-trap-like peak appears in the drain current DLTS spectra recorded from a high-electron-mobility transistor fabricated with a selectively doped AlGaAs/GaAs heterostructure grown by

molecular-beam epitaxy. The peak is caused by traps which strongly affect the mobility. The emission and the capture activation energy of the traps increases as the gate bias increases. This shows that the traps which remain at a fixed energy level relative to the GaAs conduction band edge exchange electrons with the sub-bands in the accumulation layer. Based on the above characteristics, an analysis of the spectra indicates that interface-traps with a density of  $3.8 \times 10^{10} \text{ cm}^{-2}$  are located at 0.01 eV above the conduction band edge of GaAs, in the potential well of the accumulation layer. (Author abstract) 21 refs.

Takikawa, Masahiko (Fujitsu Lab Ltd, Atsugi, Jpn). *Jpn J Appl Phys Part 1* v 26 n 12 Dec 1987 p 2026-2032.

**095787 NEW LOOK AT ZnSe/GaAs HETEROSTRUCTURES.** Contrary to some expectations for n-ZnSe/n-GaAs heterostructures, optical and electrical measurements indicate that the GaAs side of the junction is depleted of electrons, while the ZnSe side accumulates them. The low T conductance of the n-ZnSe exhibits two-dimensional metallic behavior: activated conduction is observed from 1.4 to 6 K, and a logarithmic variation of the conductance with temperature is observed between 14 and 45 K. A 0.75 V photovoltage under 5 mW  $\text{cm}^{-2}$  of white light with the GaAs negative is consistent with the theoretical predictions of Ihm and Cohen. (Author abstract) 17 refs.

**095788 REMOTE IMPURITY SCATTERING IN HETEROJUNCTIONS.** The commonly used formalism for the ionized remote impurity scattering of electrons in a 2D electron gas contains the following inconsistency. The potential of the donors (e.g. the Si donors in the AlGaAs in the case of a GaAs-AlGaAs heterojunction) is accounted for twice: first in the self-consistent calculation of the envelope function and second in the calculation of the scattering rate. Instead, only the scattering as due to the fluctuations in the average field of the donors should be accounted for. We have developed expressions for this scattering amplitude and have applied them to a few GaAs-AlGaAs samples with very high mobilities. These samples posed the problem of a serious underestimation of the experimental mobility by the theory. This problem now can be resolved and a better agreement between experiment and theory has been obtained. (Author abstract) 24 refs.

**095790 TUNNELING THROUGH SEMICONDUCTOR HETEROJUNCTION BARRIERS.** A five-level k.p-theory is presented for the description of single-particle tunneling through semiconductor barriers. The influence of the band structure is described using a local, energy-dependent effective mass  $\mu(\epsilon, z)$ . Within the barrier, the resulting 'tunneling' mass is smaller than the band edge mass of the barrier material, since the particle energy is closer to the valence band than the barrier band edge is. For GaAs-GaAlAs-GaAs structures, this effect can influence transmission rates by orders of magnitude. (Author abstract) 6 refs.

**095791 CHARACTERISTICS OF A TRANSISTOR**

**BASED ON A HETEROSTRUCTURE WITH A QUANTUM TWO-DIMENSIONAL ELECTRON CHANNEL.** In recent years there has been great interest in the study of physical processes at the interface of heterojunctions and structures based on them. This is attributable primarily to the possibility of improving the characteristics of semiconductor devices based on GaAs. The development of structures with modulated doping of the heterojunction GaAs-Ga<sub>x</sub>Al<sub>1-x</sub>As with the help of the method of molecular-beam epitaxy has made it possible not only to obtain nearly ideal interfaces, but also to achieve values of the electron mobility exceeding  $10^6 \text{ cm}^2/\text{V}\cdot\text{sec}$ . Special interest in such structures has been simulated also by the experimental observation of fractional quantization of the Hall resistance. The characteristics of a transistor based on heterostructure have been described with the help of simplified models, on the voltage and of the current on the drainage potential. The paper discusses filling of size-quantization levels with electrons and characteristics of a transistor based on a heterostructure. 5 refs.

**095792 PHASES OF THE RESISTIVITY AND THERMOPOWER OSCILLATIONS IN GaAs-Ga<sub>1-x</sub>Al<sub>x</sub>As HETEROJUNCTIONS.** We have examined the absolute and relative phases of the oscillations (at low magnetic fields) in the resistivity and thermopower of three GaAs-Ga<sub>1-x</sub>Al<sub>x</sub>As heterojunctions. The experimental value for the absolute phase of the resistivity oscillations agrees with the predicted result. We see virtually no phase difference between the resistivity and thermoelectric oscillations contrary to theoretical predictions based on the assumption that the thermopower is due to diffusion effects. This null result reinforces the view that the thermopower is mainly due to phonon drag rather than diffusion effects. (Author abstract) 13 refs.

**095793 REMOTE ION SCATTERING IN GaAs-GaAlAs HETEROSTRUCTURES.** A theoretical model of remote ion scattering in heterostructures is developed, based on the evaluation of the correlation function of the impurity potential. The method enables the consistent description of interference effects of the remote ion potentials, which are demonstrated to be particularly strong in such structures. Calculated mobilities demonstrate the invalidity of previously derived 'inherent mobility limits' motivating new considerations of relevant scattering sources. (Author abstract) 6 refs.

**095795 RADIATIVE RECOMBINATION OF A 3D-ELECTRON WITH A 2D-HOLE IN P-TYPE GaAs/(Ga)AlAs HETEROJUNCTIONS.** We have investigated an unusual new line observed in p-type GaAs/(AlGa)As heterojunctions, referred to as the H-band, by low-temperature photoluminescence experiments in magnetic fields up to 9.5 T. The direction of the magnetic field was turned from perpendicular to parallel to the interface. From the energetic shift, the splitting-behaviour, the

lineshape and the temperature dependence of the luminescence line we conclude that the H-band is emitted by the recombination of a flat-band electron with a hole confined in an excited subband. (Author abstract) 6 refs.

**095796 CHARACTERIZATION OF ULTRATHIN CaF<sub>2</sub> FILMS HETEROEPITAXIALLY GROWN ON Si(111) SURFACES.** Ultrathin CaF<sub>2</sub> films heteroepitaxially grown on Si(111) substrates have been characterized by low-energy electron energy loss spectroscopy and Auger electron spectroscopy. The measured specimens were transferred from the growth chamber to an analyzing chamber located at a distant facility without suffering any contamination by use of a newly developed portable vacuum chamber. It has been proved from the measurements that a CaF<sub>2</sub> film of good quality grows even from the very initial stage of epitaxy. (Author abstract) 10 refs.

**095797 ALLOY SCATTERING MOBILITY OF TWO DIMENSIONAL ELECTRON GAS IN RECTANGULAR AND DELTA DOPED QUANTUM WELLS IN QUATERNARIES.** The present authors have reported the calculation of alloy scattering mobility in HJs by assuming the scattering potential to be a spherically symmetric square well. This form of potential, which is the most appropriate in the presence of alloy clustering, has already been employed for bulk electrons, and for 2-DEG in ternaries. A simple analytic expression for the mobility may further be obtained when the radius of the cluster is small. In the present work, we shall extend our theory for the calculation of mobility of 2-DEG in the usual rectangular QWs and also in delta doped QWs. 15 refs.

**095799 CARRIER INJECTION AT GRADED HETEROJUNCTIONS.** Carrier injection was investigated on Ga<sub>1-x</sub>Al<sub>x</sub>As single heterostructures whose chemical composition changes near the heterojunction over an extended region. A model of the dependence of the energy bands on the coordinates allows discussion of the measured quantities, cathodoluminescence intensity and electron beam induced current (EBIC) in the context of generation, recombination, and transport of electron-hole pairs in the drift field of heterojunction. A determination of the p-n junction position is possible using the equation of continuity for EBIC. The transport of carriers from the p-n junction to the light emitting region (injection efficiency) was investigated. (Edited author abstract) 7 refs.

**095800 DETERMINATION OF BAND DISCONTINUITY IN AMORPHOUS SILICON HETEROJUNCTIONS.** A new procedure of determining the band offset in semiconductor heterojunctions has been developed. The valence band spectra for ultrathin amorphous silicon nitride ( $a\text{-Si}_{1-x}\text{N}_x\text{:H}$ ) or silicon carbide ( $a\text{-Si}_{1-x}\text{C}_x\text{:H}$ ) deposited on hydrogenated amorphous silicon ( $a\text{-Si:H}$ ) have been measured by X-ray photoelectron spectroscopy. It is demonstrated that the empirical deconvolution of measured spectra yields the valence band discontinuity in  $a\text{-Si}_{1-x}\text{N}_x\text{:H}/a\text{-Si:H}$  and  $a\text{-Si}_{1-x}\text{C}_x\text{:H}/a\text{-Si:H}$  systems. **095801 SYNTHESIS OF EPITAXIAL BUFFER LAYERS OF GERMANIUM AND GERMANIUM-SILICON SOLID SOLUTIONS ON A SILICON SUBSTRATE (REVIEW).** Research concerning the synthesis of Ge and  $\text{Ge}_x\text{Si}_{1-x}$  buffer layers during the fabrication of devices based on GaAs/Si structures is reviewed. Various methods of obtaining epitaxial films of germanium and germanium-silicon solid solutions on a silicon substrate are described. (Translated author abstract) 20 refs. In Russian.

Gurevich, V.M.; Moskalev, L.L.; Novikova, E.N. *Tsvet Met* n 11 Nov 1987 p 81-85.

**095802 ENSEMBLE MONTE CARLO SIMULATION OF SEMICLASSICAL NONLINEAR ELECTRON TRANSPORT ACROSS HETEROJUNCTION BAND DISCONTINUITIES.** An ensemble Monte Carlo simulation code has been developed to study nonlinear electron transport across heterojunction interfaces in strong electric fields. The evolution of electron energy and momentum distribution in space and time has been investigated in two AlGaAs/GaAs single well heterostructures under various operating conditions. It is found that overheating, enhanced energy relaxation, and carrier confinement as a consequence of the structure in real space have a pronounced influence on the energy and momentum distribution. As a result, the energy distribution can have a structure which directly reveals the band structure (of the material). The influence of the structure in real space and the band structure of neighboring layer on the ionization rate is discussed along with the possibility of a new overshoot effect. (Edited author abstract) 17 refs.

**095803 ANALYTICAL INVESTIGATION OF HETEROJUNCTIONS FORMED BY VACUUM DEPOSITION.** Heterojunctions formed on the surface of the II-VI materials ZnTe, ZnSe, ZnS, CdS, ZnO and  $\text{Zn}_{0.22}\text{Cd}_{0.78}\text{S}$  have been fabricated by the vacuum deposition of copper chloride. A solid state reaction has been observed to take place at the surface of each of these materials. A detailed study of this reaction has been made by energy dispersive X-ray microanalysis and reflection electron diffraction. For some of the materials a limited reaction was observed to occur at room temperature. A complete reaction was only attained by annealing in the 150°C to 200°C temperature range. The use of a variable incident electron beam energy in X-ray microanalysis as a technique for the detection of heterojunction diffusion and film thickness assessment is demonstrated. (Author abstract) 9 refs.

**095805 DEEP TRAP PARAMETERS IN  $\text{ZnSiAs}_2$  USING HETEROJUNCTION CAPACITANCE MEASUREMENTS.** Capacitance-voltage (C-V) relationship of an  $n^+0\text{-CdS}/p\text{-ZnSiAs}_2$  heterojunction has been analyzed over the frequency range of 10 Hz to 1 MHz and a temperature range of  $-20^\circ\text{C}$  to  $+60^\circ\text{C}$ , to find the deep trap parameters in  $p\text{-ZnSiAs}_2$  (hole concentration,  $p = 5 \times 10^{16}$ ). These films were grown on low resistivity Si substrates by the metal-organic chemical vapor deposition (MOCVD) technique. An electron trap was identified 0.60 eV below the conduction band edge, with a capture cross Section ( $\sigma$ ) of  $2 \times 10^{-12} \text{ cm}^2$ . Such a large value of  $\sigma$  indicates that this may be a positively charged donor-type trap. Its concentration was estimated to be about  $3 \times 10^{16} \text{ cm}^{-3}$ . (Author abstract) 13 refs.

**095806 CATION AND ANION DISPLACEMENTS AT HETERO-INTERFACES OF  $(\text{GaAs})_{28}(\text{AlAs})_{24}$  SUPERLATTICE LAYERS.** By developing a new method of Fourier analysis the local cation and anion displacements in a superlattice, especially near the hetero-interface boundary between the GaAs and the AlAs, were determined from the X-ray integrated intensities of the satellite reflections observed around the two fundamental Bragg reflections, namely the 002 and 004 reflections. The interlayer distance of successive cation layers was found to be 2.827 Angstrom in the GaAs region and 2.835 Angstrom in the AlAs region, except near the hetero-interface boundary. The anion layers are, therefore, located at the mid-point between the cation layers in these regions. However, near the hetero-interface region, which consists of eight molecular layers, anion layers are not located at the mid-point between them but are slightly shifted to the GaAs side. The value of the shift at the boundary between GaAs and AlAs was 0.016 Angstrom. (Author abstract) 3 refs.

**095808 ION CHANNELING STUDIES OF HETEROEPITAXIAL STRUCTURES FORMED BY MOLECULAR BEAM.** Epitaxial growth of  $\text{CaF}_2$  films onto Si(111) substrates and the subsequent growth of Si or Ge films onto the  $\text{CaF}_2/\text{Si}(111)$  structure have been conducted with heteroepitaxial structures of Si/ $\text{CaF}_2$ /Si(111) or Ge/ $\text{CaF}_2$ /Si(111), and then investigated by the Rutherford backscattering and ion channeling measurements. It is found that the Si film deposited on the  $\text{CaF}_2$  layer consists of the crystallites of two kinds: one with the

orientation either the same as that of silicon substrate (A type) or rotating  $180^\circ$  to the normal of the substrate surface (B type), indicating the mixture of A- and B-type crystallites in the top Si film. (Edited author abstract) 10 refs.

**095809 STUDY ON THE TRANSIENT CAPACITANCE IN HETEROJUNCTION.** The authors' theoretical analysis for the phenomenon of transient capacitance in heterojunction  $\text{CdS}/\text{CuInSe}_2$  reveals that donors are ionized by adding a reverse D. C. bias  $V_{dc}$  after a forward-biased electrical pulse  $V_p$  is switched off, and then some of the electrons produced by ionization are captured by traps and recombined with the ionized donors again via tunneling. This recombination process and the electron drifting in heterojunction region lead to the transient capacitance phenomenon. The theoretical results are in good agreement with the experimental ones. (Author abstract). 18 refs. In Chinese.

**095814 PAPERS PRESENTED AT THE AMERICAN VACUUM SOCIETY MEETING.** The conference proceedings contains three papers dealing with magnetron reactive sputtering technique for deposition of hydrogenated amorphous silicon films, semiconductor interfaces with synchrotron radiation, and investigations of the Sb/CdTe(100)-(2×1) interfacial structure with photoemission. All the papers are abstracted and indexed separately. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10841 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

Dow, John D. (Ed.). *Superlattices Microstruct* v 3 n 4 1987, Pap Presented at the Am Vac Soc Meet, Urbana-Champaign, IL, USA, Apr 1987 p 331-455.

**095815 INVESTIGATIONS OF THE Sb/CdTe(100)-(2×1) INTERFACIAL STRUCTURE WITH PHOTOEMISSION.** Clean CdTe(100) surfaces were generated by molecular beam epitaxy (MBE). High energy electron diffraction (HEED) and photoemission were used to determine surface quality and to make comparisons with surfaces generated via cycles of ion sputtering and annealing. Photoemission, HEED, and Auger electron spectroscopy were used to study the properties of the Sb/CdTe(100)-(2×1) interface. The Sb 4d core level spectrum showed a large shift (0.72 eV) in binding energy in converting from polycrystalline to the (2×2) surface. A model is proposed for the (2×2) surface structure in which Sb atoms are bonded to two Cd atoms, and Cd atoms are bonded to only one Sb atom. In order to satisfy dangling bonds, the Sb atoms also form dimer bonds with each other. (Edited author abstract) 12 refs.

**095818 TRANSPORT EQUATIONS FOR HIGHLY**

#### DOPED DEVICES AND HETEROSTRUCTURES.

An overview of the transport equations describing electron and hole motion and density in solids with nonuniform band structure is presented. This includes materials with graded composition, like heterojunctions, and devices with highly doped regions, like the emitter region of modern bipolar transistors and solar cells. Effects due to carrier degeneracy, changes in the energy band edges, and changes in the density of states produce terms in the carrier- and current-density equations in addition to those found in the conventional Shockley model. These new terms are derived and discussed. The general energy-band diagram relating the electrostatic potential, electron affinity and bandgap is given. The current densities are written in terms of gradients of quasi-Fermi level and the carrier densities in terms of normalization integrals. The concepts of generalized drift and diffusion are discussed. Connections to the work by Van Overstraeten et al. and to Lundstrom et al. are given. The transport equations in the nondegenerate limit are presented. The special case of minority-carrier flow in quasi-neutral material is given. Approximations used in device analysis are discussed. (Edited author abstract) 15 refs.

**095820 HETEROJUNCTIONS: SOME KNOWN AND UNKNOWN.** Aspects of heterojunctions that are discussed are the limitations of models and the accuracy of experimental measurements of barriers. Lattice matching and interface states are discussed and some recent bandgap engineering concepts are mentioned. (Author abstract) 34 refs.

Milnes, A.G. (Carnegie-Mellon Univ, Pittsburgh, PA, USA). *Solid State Electron* v 30 n 11 Nov 1987, New Dev in the Phys of Homo- and Heterojunctions, US-Belg Jt Semin, Louvain, Belg, May 28-30 1986 p 1099-1105.

**095821 OPTIMIZATION OF II-VI BASED HETEROJUNCTIONS.** The performance of heterojunction devices can be optimized by proper choice of characteristics of the two semiconductors forming the junction and by proper design. One important element in design is the termination of the active volume of the device with surfaces of low, preferably zero surface recombination velocity. This paper discusses the rules governing the choice of ratios of energy gaps, electron affinities, doping levels, minority carrier lifetimes, lattice constants, etc. for the semiconductors comprising the pair. It also discusses the use of heterostructures to produce the low surface recombination velocity surfaces bounding the active volume of the device. The paper reviews principles of materials science which govern the choice of semiconductors for the active regions of the device and the heterostructure 'encapsulants'. Attempts to realize electronic structures having the properties required by optimization theory are described. (Edited author abstract) 7 refs.

Loferski, Joseph J. (US Embassy, Warsaw, Pol). *Solid State Electron* v 30 n 11 Nov 1987, New Dev in the Phys of Homo- and Heterojunctions, US-Belg Jt Semin, Louvain, Belg, May 28-30 1986 p 1205-1213.

**095822 II-VI HETEROJUNCTION DEVICE PHYSICS.** II-VI compounds are mainly used for their

large bandgap. They serve as host materials in electroluminescent devices and as collector or window materials in thin film solar cells. Besides the band discontinuities, the physics of II-VI heterojunctions depends on the presence of deep trap levels within the large bandgap. As a typical example we treat the crossover phenomenon, which can be observed in heat-treated  $\text{Cu}_2\text{S}/\text{CdS}$  thin film solar cells. (Edited author abstract) 24 refs.

**095823 THEORETICAL ASPECTS OF ELECTRON TRANSPORT IN MODULATED STRUCTURES.** We have studied transport both perpendicular and parallel to the heterojunction interfaces. For perpendicular transport we have investigated models for tunneling through double barriers and find that resonant tunneling and sequential tunneling lead to the same expression for the current as long as the width of the energy distribution of the injected electrons is larger than the width of the resonant level in the diode. We present results for phonon-assisted tunneling between two wells in a model which remains valid even when the barrier shrinks and the tunneling probability becomes very high. For parallel transport we show that very satisfactory agreement with extensive measurements of the mobility in modulation doped structures in the whole temperature range from 4 K to 300 K can be obtained if one takes into account the complete quasi-two-dimensional subband structure and all the relevant scattering mechanisms. For systems with more complicated double channel structures it is shown how one can tailor the conductivity of a channel in which perpendicular resonant tunneling affects parallel transport. **095824 TRANSIENT AND STEADY-STATE RESPONSE OF THE TWO-DIMENSIONAL ELECTRON GAS IN HETEROJUNCTIONS SUBJECT TO AN EXTERNAL ELECTRIC FIELD.** The time-dependent linearized Boltzmann equation is solved accurately by a new self-consistent algorithm to obtain the time-dependent subband distribution functions in response to a step-wise electric field applied parallel to the AlGaAs-GaAs heterojunction interface. This study is for the polar optical phonon-electron scattering only. Both intra- and inter-subband scatterings are included. It is found that the energy-dependent subband relaxation time oscillates with a period equal to the polar optical phonon energy of 36 meV as the relaxation time is plotted against energy. The short time transport behavior is found to be restricted to within a few picoseconds. The electrons drift in a free-streaming fashion in a time scale of a few hundred femtoseconds. The time-dependent mobility begins to saturate at the steady state value in one picosecond at 300 K and 50 picoseconds at 77 K. (Author abstract) 12 refs.

**095826 PRESSURE DEPENDENCE STUDY OF THE EFFECTIVE MASS IN  $\text{Ga}_{0.47}\text{In}_{0.53}\text{As/InP}$  HETEROJUNCTIONS.** A study of the effective mass in  $\text{GaInAs/InP}$  heterojunctions under hydrostatic pressure up to 15 kbars is presented. Magnetophonon resonance experiments are performed to work out the increase of mass with pressure in our samples. The effective mass at atmospheric pressure is deduced from high temperature cyclotron resonance experiments and then used to calculate the frequency of the phonon interacting with the 2D electron gas ( $w_0$ ). The value of  $w_0$  is found to be dependent on the carrier concentration of the measured samples. The lowest value is found for the highest carrier concentration sample. A band edge effective mass increase of  $1 \pm 1\%$  kbar is found in the highest carrier concentration sample. (Edited author abstract) 13 refs.

**095827 REAL SPACE TRANSFER: GENERALIZED APPROACH TO TRANSPORT IN CONFINED GEOMETRIES.** Research on transfer of electrons between semiconductor heterolayers is reviewed and its importance and applications in new forms of heterolayer-structures are discussed. It is shown that the massive transfer of hot electrons transversal to the layers is interesting from both a device and a physics point of view due to the high speed of the effect and due to its dependence on the details of the electron energy distribution under conditions far away from equilibrium. Less visible is the spreading of hot electrons in confining fields such as the gate field in field effect transistors. This spreading can be viewed as a real space transfer effect and causes additional mobility degradation and generally the enhancement of effects of nonlinear transport, notably impact ionization. The transfer of minute electron numbers from silicon into silicon dioxide appears as a special case of real space transfer from this point of view. It is shown that a complete understanding of this latter effect involves complex quantum-transport principles. Details of nonlinear transport of electrons over a well structure is discussed. It is shown that interesting combinations of k-space and real space transfer effects can be achieved which have new applications. The effects demonstrate the influence of the band-structure (band-gap engineering) on the energy distribution function of the electrons. (Edited author abstract) 18 refs.

**095829 ON THE ANALYTICAL APPROACH TO**

**THE REAL SPACE ELECTRON TRANSFER IN  $\text{GaAs-AlGaAs}$  HETEROSTRUCTURES.** Real space electron transfer (RSET) in modulation-doped heterostructures is analyzed in the frame of the analytical model for large layer widths ( $\geq 0.04 \mu$ ) proposed by Shichijo and co-workers (1980). It is shown that in high electric field parallel to the interface there is a discontinuity in electron temperature at the boundary between two materials. The model of Shichijo and co-workers is therefore modified using an appropriate boundary condition for electron temperature. In order to compare the modified model with Shichijo and co-workers' results their calculations are reexamined. We obtained different results which are qualitatively much closer to Monte Carlo results of Glisson and co-workers (1980). Taking into account the nonparabolicity of the central valley the influence of the electron temperature discontinuity was found to be apparent. Our analytical approach with Monte Carlo calculations. The approach for heterostructures consisting of central valley dominated materials is discussed. (Edited author abstract) 7 refs.

**095830 DIFFUSION COEFFICIENTS OF TWO-DIMENSIONAL ELECTRON GAS IN HETEROJUNCTIONS.** This paper presents a Monte Carlo study of diffusion and noise in Two-Dimensional Electron Gas (2DEG) in  $\text{AlGaAs-GaAs}$  heterojunctions. This is achieved by the calculation of the velocity fluctuations correlation functions of the gas subjected to a driving field applied along the channel. It is found that at low fields when the carriers have a real two-dimensional motion, the parallel correlation functions show oscillations which we analyse in terms of scattering rates. This gives rise to resonant noise spectra whose resonance frequency is nearly proportional to the driving field strength. At higher fields the behavior is similar to what occurs with bulk electrons. (Edited author abstract) 19 refs.

**095831 REDUCED INTERVALLEY TRANSFER IN A  $\text{GaAs-AlGaAs}$  HETEROJUNCTION.** In a Monte Carlo calculation aimed at studying the electron transport along the interface of a  $\text{GaAs-AlGaAs}$  heterojunction the electrons in the conducting channel have been found to exhibit higher steady-state velocities than in bulk  $\text{GaAs}$ , although effects such as degeneracy, subband scattering or remote impurity scattering were not taken into account. The effect is ascribed to the strong transverse electric field near the interface which reduces intervalley scattering, resulting in the higher velocities. (Author abstract) 7 refs.

**095833 ELECTRON TRANSPORT IN  $\text{GaAs/Al}_x$**

**$\text{Ga}_{1-x}\text{As}$  HETEROJUNCTIONS AT LOW TEMPERATURES.** We have performed Monte Carlo studies of transient and steady-state low temperature (10 K) transport for electrons in  $\text{GaAs/Al}_x\text{Ga}_{1-x}\text{As}$  single-well heterojunction structures. Besides polar optical, acoustic phonon (coupled by the deformation potential potential or piezoelectrically), and ionized impurity scattering we account for the interactions between the electrons through the effect of plasmons and single pair collisions. Results of ensemble Monte Carlo simulations for several values of the electric field are shown, pointing out the effect of the various scattering mechanisms on the electron velocity and distribution function. Our results do not confirm theoretical reports of scattering induced negative differential resistance. (Edited author abstract) 15 refs.

**095835 HOT ELECTRON ENERGY RELAXATION VIA ACOUSTIC PHONON EMISSION IN  $\text{InP/In}_{0.53}\text{Ga}_{0.47}\text{As}$  HETEROSTRUCTURES AND SINGLE QUANTUM WELLS.** A study of the electron heating processes in modulation doped  $\text{Ga}_{0.47}\text{In}_{0.53}\text{As/InP}$  heterostructures (SHJ) and single quantum wells (SQW) by magnetotransport measurements at low temperatures is presented. For electron temperatures below 20K both the SHJ and SQW show a power loss  $P_p$  ranging between  $P \propto T_e^{-3}$  and  $P \propto T_e^{-5}$  suggesting that energy relaxation occurs by acoustic phonon emission via mixed unscreened piezoelectric and deformation-potential interactions. In SHJ samples above  $T_e \geq 10\text{K}$  an extra inelastic scattering mechanism appears. (Edited author abstract) 11 refs.

**095837 BREAKDOWN OF COHERENCE IN RESONANT TUNNELING THROUGH DOUBLE-BARRIER HETEROSTRUCTURES.** We report measurements of current-voltage characteristics of symmetric and asymmetric  $\text{AlGaAs/GaAs}$  double-barrier resonant tunneling structures (DBRTS) which exhibit intrinsic bistability. We interpret the data within a self-consistent model which takes into account the space-charge formation in

DBRTS and show that the intrinsic bistability is due to the feedback of the electrostatic field of the electrons in the well on the tunneling current density. We argue that the electron-electron interaction in the well destroys the coherence of tunneling. (Author abstract) 10 refs.

**095838 MEASUREMENTS OF HOT ELECTRON MAGNETOPHONON RESONANCE IN GaAs/GaAlAs HETEROSTRUCTURES.** Hot electron magnetophonon resonances have been directly observed in GaAs/GaAlAs heterojunctions between 30 and 100K and their temperature and electric field dependences studied. The oscillation amplitude is seen to have a maximum at 60K, which is attributed to the influence of temperature dependent level broadening on the electron flow through energy space. The resonance positions indicate phonon frequencies close to the bulk TO value, as observed in normal magnetophonon resonances in heterojunctions, rather than the expected LO frequency. In samples of higher electron concentrations a second series of resonances is observed at low electric fields which we believe to be due to inter-subband scattering. (Author abstract) 13 refs.

## Imaging Techniques

**095841 HIGH-FREQUENCY DIFFERENTIAL PIEZOELECTRIC PHOTOACOUSTIC INVESTIGATION OF ION-IMPLANTED (100) SILICON WAFERS VIA LASER BEAM POSITION MODULATION.** An exploratory application of position-modulation photoacoustic imaging of ion-implanted (100)-oriented Si wafers was undertaken to assess its potential as a diagnostic probe in semiconductor processing. Wafer scans were performed using acoustooptic modulation of a 1.06- $\mu m$  Nd<sup>3+</sup>:YAG laser beam up to 0.2 MHz with piezoelectric photoacoustic detection. Sensitivity ranges to ion-implanted parameters (ionic species and fluences)

were studied and the capability of the technique to monitor processing-induced damage was established. Results indicate that position-modulated photoacoustic detection offers higher sensitivity than single-beam photo-thermal imaging and has distinct advantages over other analytical techniques. 45 refs.

**095842 ANALYSIS OF ELECTRIC FIELD DISTRIBUTIONS IN ULTRA-SHALLOW SILICON JUNCTIONS UNDER THERMODYNAMIC EQUILIBRIUM CONDITIONS.** A comprehensive analysis of electric field distributions in ultra-shallow, heavily-doped, strongly-asymmetric silicon n-p junctions is performed under thermodynamic equilibrium conditions. The physical deficiencies of previous approaches to the built-in electric field computations in such very steep junctions are examined on the grounds of semiconductor fundamentals. It is shown that in the surface-controlled region of ultra-shallow silicon junctions the built-in field  $E$  calculations depart from the bulk-type computations precisely in view of the peculiar physical features of the semiconductor surface (discontinuities of impurities, surface states, etc.). The results of this work suggest that all processes in the surface-controlled region of the heavily doped layer in ultra-shallow silicon junctions are being shaped by the peculiar interplay of the bulk field  $E$  created by the impurity gradients with the field  $E_{surf}$  originated in the surface states. (Edited author abstract) 24 refs.

**095845 NUMERICAL EVALUATION OF THE SCANNING METHOD FOR THE DETERMINATION OF MINORITY CARRIER DIFFUSION LENGTH IN p-n JUNCTIONS.** A numerical model for the scanning method for determining minority carrier diffusion length is presented to include the effect of the

built-in field and high-level injection. A numerical simulation is presented which shows that the scanning method for diffusion length measurements will not give accurate results for minority carrier diffusion length in the region where the presence of a built-in field is significant. No matter how poor the junction is made, the accuracy of the measurement method increases away from the depletion region. The problem of low magnitude in the induced short circuit current away from the physical junction could be overcome by increasing the generation level. For substrate dopant concentrations between  $2.0 \times 10^{15} \text{ cm}^{-3}$  and  $6.0 \times 10^{16} \text{ cm}^{-3}$  the distance into the device from the surface where the error of the measurement will be greater than 10% is expressed as a semi-empirical formula relating dopant concentration. (Edited author abstract) 10 refs.

**095849 SELF-ALIGNED TITANIUM SILICIDED JUNCTIONS FORMED BY RAPID THERMAL ANNEALING IN VACUUM.** New self-aligned silicided junctions have been developed by rapid thermal annealing in vacuum for applications to VLSI technology. These silicided junctions were investigated in regard to sheet resistance, junction depth, junction leakage current, and impurity depth profiles. After Ti film (35 nm) was deposited by dc magnetron sputtering, Si<sup>+</sup> was implanted for interface mixing and rapid thermal annealing (RTA) in vacuum (approximately  $10^{-1}$  Pa) was performed in temperature range of 550<sup>o</sup>-750<sup>o</sup>C. In these temperature ranges, the lateral growth of titanium silicide was prevented. After Si<sup>+</sup> implantation through the titanium

silicide layer to amorphize the Si substrate, As<sup>+</sup> and + ions were implanted for n<sup>+</sup>/p junction, and p<sup>+</sup>/n junction, respectively. (Edited author abstract) 19 refs.

**095851 100 NM DEEP p<sup>+</sup>/n JUNCTIONS WITH SELF-ALIGNED SILICIDED CONTACTS.** Shallow p<sup>+</sup>/n junctions have been formed with CoSi<sub>2</sub> contact layers. Specifically, an 11 nm thick Co film sputter deposited onto <100> Si that has been pre-amorphized with Sn<sup>+</sup> and implanted with BF<sub>2</sub><sup>+</sup>, is rapidly thermally annealed for 1 sec at 100°C. The result, after selective wet chemical etching, is a self-aligned 39 nm thick CoSi<sub>2</sub> layer on a 73 nm deep p<sup>+</sup>/n junction. The junctions have the following characteristics: sheet resistance of 8.6Ω/sq, electrical activity exceeding 1×10<sup>20</sup> carriers cm<sup>-3</sup>, reverse-bias leakage of -2na cm<sup>-2</sup> at -5 v and a forward-bias ideality factor of 1.08 from 5×10<sup>-12</sup> to 1×10<sup>-4</sup>A. Some reduction of SiO<sub>2</sub> by Co occurs during annealing. Identical results and essentially no reduction of SiO<sub>2</sub> are achieved using a two-step annealing: 10 sec at 700°C, prior to selective etching, followed by 1 sec at 1000°C. (Author abstract) 21 refs.

**095854 COHERENT VOLTAGE OSCILLATIONS IN SMALL NORMAL TUNNEL JUNCTIONS AND THE Crossover TO THE INCOHERENT REGIME.** We discuss the possibility of charge oscillations in a normal tunnel junction, driven by an external current source ( $I_{ex}$ ), in the coherent limit. In that limit the dephasing time  $t_d$  is larger than the period  $t_p = e/I_{ex}$ . This

behavior is modified when  $t_d$  decreases. (Author abstract) 19 refs.

**095855 CORRELATED DISCRETE TRANSFER OF SINGLE ELECTRONS IN ULTRASMALL TUNNEL JUNCTIONS.** Recent theoretical and experimental studies have revealed a new family of effects taking place in very small tunnel junctions at low temperatures. The effects have a common origin, the correlated discrete tunneling of single electrons and/or Cooper pairs resulting from their electrostatic ('Coulomb') interaction. This paper presents a brief review of the single-electron part of the family, including discussion of the background physics, methods of theoretical description of the new effects, experimental results, and possible applications of the new effects in analog and digital electronics. (Author abstract) 47 refs.

**095856 CIRCUIT TECHNIQUE FOR SEMICONDUCTOR-DEVICE ANALYSIS WITH JUNCTION DIODE OPEN CIRCUIT VOLTAGE DECAY EXAMPLE.** The application history of the circuit technique for semiconductor-device analysis is reviewed with a discussion of its specific application advantages, including providing accurate solutions. An illustration of the use of this technique for the time dependence of the open circuit voltage decay across an initially forward biased p/n junction is given. The illustration also presents a new solution method of the lumped model which gives the correct time dependence for the initial transient. (Edited author abstract) 46 refs.

**095857 PHOTON EMISSION FROM REVERSE-BIASED SILICON P-N JUNCTIONS.** An analytical theory has been developed for the light emission of a reverse-biased silicon p-n junction. Based on the theory of ionization and indirect recombination of electrons and holes under high-field conditions, the relative intensity of emitted light has been derived. It is observed that the normalized results of intensity are in good agreement with the experimental results for an electron ionization length  $l_{ioe} = 60$  Å, and a hole ionization length  $l_{ioh} = 70$  Å. Thus it confirms the validity of this theoretical model for light emission in a reverse-biased silicon p-n junction. (Author abstract) 16 refs.

**095858 ANOMALOUS TENSOELECTRIC EFFECTS IN GALLIUM ARSENIDE TUNNEL DIODES.** Anomalous tensorial phenomena induced in a tunnel p-n junction by a concentrated load and by hydrostatic compression were studied. The anomalous tensorial effects are caused by the action of concentrators of mechanical stresses in the vicinity of the p-n junction, giving rise to local microplastic strain. Under the conditions of hydrostatic compression prolate inclusions approximately 100-200 Å long play the role of concentrators. Analysis of irreversible changes in the current-voltage characteristics of tunnel p-n junctions made it possible to separate the energy levels of the defects produced with plastic strain of gallium arsenide. (Author abstract) 18 refs.

**095859 APPLICABILITY LIMIT OF THE DIFFUSION APPROXIMATION IN THE THEORY OF MULTILAYER SEMICONDUCTOR STRUCTURES.** The influence of nonlinear effects such as electron-hole scattering, Auger recombination, and a reduction of the

injection coefficients of emitter p-n junctions on the realizability of the diffusion regime of operation of multilayer semiconductor structures at a high charge-carrier injection level is investigated. A successive change in the operating regime of the structure is shown to be possible with an increase in the amount of current flowing through it as a function of the ratio of characteristic parameters - the thickness of the base layer, the diffusion length of charge carriers in it, the saturation currents of the emitter layers, etc. (Author abstract) 2 refs.

**095860 CONCISE AND COMPLETE SOLUTION FOR LINEARLY GRADED p-n JUNCTIONS.** We present a highly condensed solution consisting of the profiles for potential, electric field, net charge density and net mobile to net fixed charge density ratio, all as functions of distance for linearly graded p-n junctions. The condensed representation results from the use of the transformations for the potential and the distance variables proposed earlier. The important features of this solution are discussed and compared with the results of the depletion approximation. The method of using this solution to extract numerical results in specific situations is demonstrated. The new scaling length used successfully in the distance transformation is compared with those previously used in the literature and some general relationships connecting them are established. The depletion widths under different normalizations are compared. (Edited author abstract) 7 refs.

**095861 EFFECTS OF TITANIUM SILICIDE FORMATION ON DOPANT REDISTRIBUTION.** This paper reports on boron and arsenic redistribution during the TiSi<sub>2</sub> self-aligned silicide process as applied to shallow (<0.2 μm) junctions. Dopant loss was seen to occur through evaporation from the silicide surface, segregation into the Ti-rich outer layer which is subsequently removed, and diffusion into the silicide layer. Depending on the silicide and junction annealing temperatures, up to 99% of the implanted dopant dose can be lost via these three mechanisms. Dopant loss is particularly acute when the silicide is formed concurrently with recrystallization annealing of the junction implant, before the dopant diffuses into the silicon. (Edited author abstract) 56 refs.

**095862 STEADY STATE PHOTOCAPACITANCE STUDY OF SEMICONDUCTOR/AQUEOUS ELECTROLYTE JUNCTIONS: I. INTEREST AND DIFFICULTIES IN THE CASE OF n-GaAs.** The photocapacitance (PC) technique allows the determination of deep-level as well as surface states at semiconductor/electrolyte (SC/EL) contacts. Expressions of the PC signal, given in several peculiar cases, help in the understanding of the results obtained with GaAs in contact with an aqueous electrolyte. It is found that relevant experimental conditions of band bending and/or incident photon flux are required to detect transitions which have a small magnitude compared to the large response due to EL2 in GaAs. A quantitative interpretation of the spectrum is also given. (Author abstract) 6 refs.

**095863 EFFECT OF ABSORPTION ON PHOTON EMISSION FROM REVERSE-BIASED SILICON P-N JUNCTIONS.** An analytical expression for the intensity of the emitted light has been derived from reverse-biased silicon p-n junction. Based on the theory of ionization and recombination, the intensity of light has

been calculated by taking the emission and absorption phenomena simultaneously. It is observed that the normalized results of the intensity agree with the reported experimental results in all the energy ranges of photons. Thus it confirms the validity of the developed theoretical model for light emission in a reverse-biased silicon p-n junction. 11 refs.

**095864 QUANTUM OSCILLATIONS IN COUPLED SINGLE ELECTRON TUNNEL JUNCTIONS.** It has been proposed that the frequency of the voltage oscillations associated with single electron tunneling (SET) in ultra-small junctions can be used for measuring electrical current at a higher degree of accuracy and resolution than earlier methods. To get rid of parasitic capacitances these SET junctions are made in pairs, coupled in series. A coupled nonlinear system is often expected to have a complex behavior. Such complex behavior will inhibit the function as a current meter. Therefore a detailed analysis of the coupled system is necessary and has been done here. We use an equivalent model to study the time dependence of the voltage oscillations across such a pair. Measurements on a test circuit as well as numerical studies of the corresponding theoretical model show that there is a large current interval where there is a simple functional relationship between the current driven through the circuit and the oscillation frequency. Multiperiodic behavior is also observed in the lower part of the current interval where oscillations are possible. (Edited author abstract) 6 refs.

**095866 STEADY STATE PHOTOCAPACITANCE STUDY OF SEMICONDUCTOR/ELECTROLYTE JUNCTIONS II. SURFACE STATE DISTRIBUTION AND CHARGE TRANSFER MECHANISMS.** GaAs/electrolyte junctions are characterized by steady state photocapacitance measurements without (single beam experiment) or with added interband illumination (dual beam experiment). This original approach allows to give unambiguously the surface state distribution and to follow its evolution during electrochemical processes; results show the presence of two corrosion related states at  $E_c - 0.98$  eV and  $E_c - 1.14$  eV which behave differently under corrosion or photocorrosion conditions. It is shown that surfaces modified by electro-deposition of discontinuous and metal films exhibit metal-induced surface states responsible for charge transfers. (Author abstract). 41 refs.

Allongue, P. (CNRS). *Ber Bunsenges Phys Chem* v 92 n 8 Aug 1988 p 895-903.

**095867 CHARGE TRANSPORT IN SEMICONDUCTOR MICROJUNCTIONS.** P-n junctions of silicon-wedge microcontacts with variable constrictions down to 0.1  $\mu$ m diameter exhibit current transport behavior completely different from the conventional large-area junctions. Generation and recombination dominate for junctions larger than 1  $\mu$ m diameter; smaller junctions show a predominance of space charge and resistive effects. (Author abstract). 15 refs.

**095871 CURRENT GENERATION MECHANISMS IN SMALL BAND GAP HgCdTe p-n JUNCTIONS FABRICATED BY ION IMPLANTATION.** A detailed study has been made of the current-voltage characteristics of Hg<sub>1-x</sub>Cd<sub>x</sub>Te ion-implanted p-n junctions with  $x \approx 0.224$ . It is found that the dark currents, for diodes of high quality, can be represented over a broad range of voltage and temperature by three current components. A diffusion current dominates in the small bias region at temperatures > 50 K. This current component is also observed at sufficiently high forward biases at low temperatures. At temperatures of  $30 < T < 50$  K in the small bias region, a current component with a positive temperature coefficient is observed. This component, which we call Type II tunneling, has a logarithmic voltage dependence in forward bias and some of the properties of this current can be accounted for by trap-assisted tunneling models for excess current in Esaki diodes. ## Manufacture

**095874 SUCCESSFUL CLEAN ROOM DESIGN.** Manufacturing semiconductor chips with submicron line widths requires an ultra clean environment. This minute geometry is extremely sensitive to any type of contamination, and the denser the circuit on the chip, the more stringent are its cleanliness and temperature control requirements. The key to meeting these requirements is the HVAC system with vertical laminar flow (VLF) characteristics. 2 refs.

Schafer, Norman; Kotz, Donald A. *ASHRAE J* v 29 n 9 Sep 1987 p 25-28.

**095875 COMPARISON OF TWO WAFER INSPECTION METHODS FOR PARTICLE MONITORING IN SEMICONDUCTOR MANUFACTURING.** The two methods examined differ in the procedure used to select wafers for inspection. In the first, or fixed-policy, method, the same number of wafers is inspected regardless of defect density. In the second method a variable policy is used. It is found that in a superclean production environment these inspection methods are not equivalent in defect density estimation: estimates obtained by the variable policy may be biased, while those obtained with the fixed policy are always unbiased. Fundamental reasons for such a phenomenon are discussed and recommendations are made. 3 refs.

**095877 ZIRCON PHOSPHATE MATERIAL FOR COATING VITREOUS SILICA.** A method involving the photocolometric determination of zirconium and phosphorus was developed at the State Scientific-Research Institute of Vitreous Silica for the investigation of the chemical composition of a coating containing 60% zirconium and 10% phosphorus. The method is based on the fact that zirconium forms with arsenic III a colored complex compound in the acidity range of 1-3 relative to HCl. The x-ray phase analysis showed that with an increase in the concentration of  $P_2O_5$  in the original material, the amount of zirconium pyrophosphate in the coating increases after heat treatment. In this case the strength of the zircon phosphate material increases. Thus, the compressive strength of specimens with a concentration of 20% of  $ZrP_2O_7$  was 30 MPa. The use of the results of the reported studies has made it possible to optimize the production process of applying zircon phosphate coatings to articles made of vitreous silica to be used in the semiconductor industry. 1 ref.

**095878 HEAVY METAL GETTERING IN BURIED NITRIDE SILICON-ON-INSULATOR STRUCTURES.** Using Rutherford backscattering spectrometry the redistribution and gettering of implanted gold was investigated in silicon-on-insulator structures produced by high-dose nitrogen implantation. The gettering efficiency of a structure annealed at 1000°C containing a highly damaged silicon region near to the buried compound layer is more pronounced than that of a 1200°C-annealed structure with a lightly damaged silicon top layer. Gettering takes place at the interregion between silicon and silicon nitride. (Author abstract) 8 refs.

Skorupa, W. (Acad of Sciences of GDR, Dresden, East Ger); Knothe, P.; Groetzschel, R. *Electron Lett* v 24 n 8 Apr 1988 p 464-465.

**095879 DOPANT DIFFUSION IN SELF-ALIGNED SILICIDE/SILICON STRUCTURES.** Modern micro-electronic devices employ transition metal silicides in self-aligned structures on highly doped silicon material. Thermal treatments during or following silicide formation can significantly alter the dopant concentration in the underlying silicon layer. This paper discusses various diffusion mechanisms in self-aligned silicide structures and their effect on device performance. (Author abstract). 22 Refs.

Wittmer, Marc (IBM, Yorktown Heights, NY, USA). *J Electrochem Soc* v 135 n 8 Aug 1988 p 2049-2053.

**095880 POROUS SILICON TECHNIQUES FOR SOI STRUCTURES.** The two principal silicon-on-insulator fabrication techniques are examined. The first is by buried porous Si formation; areas surrounding device islands are converted into porous Si by proper tailoring of the wafer dopant profile. It is known as FIPOS (full insulation by porous oxidized silicon). The second is by epitaxy on porous Si; a uniform surface porous Si layer is used as a seeding layer for low-temperature epitaxy of the device Si. Oxidation of the underlying porous Si layer, via trenches in the device Si, has been improved to the point that defect generation and wafer warpage are avoided. Fabrication of advanced devices on the FIPOS material has shown that the porous silicon technology is among the front-runners for high-performance CMOS LSIs. 27 refs.

**095881 MODELLISTICA DEI DISPOSITIVI A SEMICONDUCTORE.** [Modeling of Semiconductor Devices]. Physical models, numerical methods and potentialities of modern programs of simulation of electronic semiconductor devices are presented, with special reference to the system developed in the course of the last five years at the University of Bologna. The problems of analysis under static, dynamic and small-signal conditions are examined in detail from the numerical point of view, and some examples are illustrated in which use is made of the algorithms described. A method of analysis of sensitivity of the electric characteristics to the variations of the physical (impurity profiles), and geometric structure of the devices is presented. Finally, a model of transport in semiconductors based on the first and second order moments of the Boltzmann equation is illustrated. This is the so-called 'hydrodynamic' model which overcomes some limitations of the classic transport model based on 'drift' and diffusion. (Translated author abstract) In Italian. 23 refs.

**095882 NON-QUASI-STATIC CAPACITANCE OF P/N JUNCTION SPACE-CHARGE REGIONS.** The effect of the free-carrier delay time on the space-charge-region capacitance is investigated and a method of finding such capacitance is developed. The method, which is based on a comprehensive quasi-static space-charge-region capacitance model and on the concept of the delay time in the region, describes the non-quasi-static capacitance for all voltages, all frequencies, and for both step and linear-graded junction profiles. The method requires a simple numerical iterative procedure. The results from the present method show good agreement when compared with a numerical method based on Sah's transmission-line equivalent circuit model and with measured dependencies. The method provides a tool for more accurate semiconductor device modeling and for integrated circuit simulations. (Author abstract) 16 refs.

**095883 EVOLUTION SYSTEMS IN SEMICONDUCTOR DEVICE MODELING: A CYCLIC UNCOUPLED LINE ANALYSIS FOR THE GUMMEL MAP.** The initial/boundary-value problem for isothermal, lattice, semiconductor device modeling is described and analyzed. This nonlinear elliptic/parabolic system of reaction/diffusion/convection type is determined by a Maxwell equation, relating space/charge and the electric field, and by two continuity equations for the free electron and hole carrier concentrations. The Einstein relations for Brownian motion are not assumed in this analysis, so that the electrostatic potential,  $u$ , and the carrier concentrations,  $n$  and  $p$ , are the fundamental dependent variables of the system. The boundary conditions are Dirichlet conditions for dependent variable values on the contact portions of the device, and homogeneous Neumann conditions, expressing insulation, on the complement. Complicating the analysis are the transition singularity points between the mixed boundary conditions, and the field dependence of the mobility and diffusion coefficients. By means of a physically motivated analysis of the convective current component, we are able to uncouple the system by a cyclic horizontal line analysis, without an unreasonable time step restriction. (Edited author abstract) 21 refs.

Jerome, J.W. *Math Methods Appl Sci* v 9 n 4 1987 p 455-492.

**095884 SECOND ORDER DIFFERENCE SCHEME FOR TRANSIENT SEMICONDUCTOR DEVICE SIMULATION.** A second order scheme for the solution of the transient fundamental semiconductor device equations is presented which does not suffer from

timestep restrictions due to the stiffness of the analytical problem. The second order accuracy as well as the stability properties are demonstrated on the simulation of a p-n-junction diode. (Author abstract) 12 refs.

Ringhofer, Christian A. (Arizona State Univ, Tempe, AZ, USA). *Trans Soc Comput Simul* v 3 n 4 Oct 1986 p 253-278.

**095885 NUMERICAL SOLUTION OF THE HYDRODYNAMIC MODEL FOR A ONE-DIMENSIONAL SEMICONDUCTOR DEVICE.** A numerical implementation of a discretization scheme of the hydrodynamic model for submicron devices is described and applied to a one-dimensional ballistic diode. The performance of the numerical method and the physical results of the simulation for different biases and lattice temperatures, and a brief comparison to Monte Carlo simulations, are also given. (Author abstract) 16 refs.

**095886 ANALYSIS OF A DISCRETIZATION ALGORITHM FOR TIME-DEPENDENT SEMICONDUCTOR MODELS.** A new algorithm is presented for the discretization of semiconductor models in one space dimension plus time. A complete error analysis is given, showing that the discretization errors do not depend on any derivatives of ill-behaved quantities such as carrier densities. In this algorithm, the electrostatic potential is updated from a discretization of the equation of total current continuity, and parabolic equations for the current densities are discretized, rather than those for the carrier densities. Projection methods, e.g. simple finite-element methods, are used for the space discretization. The equations for the current densities are similar to the familiar Scharfetter-Gummel expressions in the stationary limit. This method is fully compatible with recently developed methods for uncoupling the discrete systems to be solved at each time step, for an individual device or when a given problem involves multiple, coupled devices. (Edited author abstract) 13 refs.

**095887 NUMERICAL ANALYSIS OF THE TRANSPORT PHENOMENON IN SEMICONDUCTOR DEVICES AND STRUCTURES. 5. THREE-DIMENSIONAL MODELING OF VLSI ELEMENTS.** A change in the configuration of the components in the plane of the crystal, i.e., their topology, is the approach approved in practice for improving the characteristics of LSI and VLSI elements. In this case, despite the possible significant machine time expenditures, the three-dimensional modeling of transport processes occurring in the elements is necessary in principle. The high efficiency of a multidimensional numerical analysis of semiconductor devices is confirmed in an example of three-dimensional modeling of bipolar integral circuit structures. (Edited author abstract) 17 refs.

**095889 ON THE CONDITIONING OF THE STEADY STATE SEMICONDUCTOR DEVICE PROBLEM.** In this paper we carry out a conditioning analysis for the steady state semiconductor device problem. We consider various quasilinearizations as well as Gummel-type iterations and obtain stability bounds which may allow ill-conditioning in general. These bounds are exponential in the potential variation, and are sharp e.g. for a thyristor. But for devices where each smooth subdomain has an Ohmic contact, e.g. a pn-diode, moderate bounds guaranteeing well-conditioning are obtained. Moreover, the analysis suggests how various row and column scaling should be applied in order for the measured condition numbers of the linearized discrete problem to correspond more realistically to the true loss of significant digits in the calculations. (Author abstract) 7 refs.

**095891 ADAPTIVE MESHING APPLIED TO A TWO-DIMENSIONAL DEVICE SIMULATOR.** The purpose of using an adaptive meshing strategy is to define the problem well with as few nodes as possible. The extent to which the discrete system adequately represents the problem being solved depends on the positioning of the grid points. It is the intention to show here that adding badly placed nodes to the region of interest in a mesh can reduce the accuracy of the resulting solution. A practical refinement strategy is presented where such problems are avoided. (Author abstract) 3 refs.

**095892 SIMPLIFIED DEVICE EQUATIONS AND TRANSPORT COEFFICIENTS FOR GaAs DEVICE MODELING.** In the analysis of submicrometer GaAs devices, consideration of hot-electron effects is imperative. A generalized current equation suggested by K.K. Thornber (1982) allows the inclusion of some of the hot-electron effects into standard drift/diffusion device models, and hence does not require too large computational resources. Here the authors report gradient and rate coefficient tables (graphs) that are necessary to complement the standard approach for electrons in GaAs at 300 K as calculated by Monte Carlo methods. 14 refs.

**095893 CHARGE-INJECTION DEVICES - II: MULTIPLE-PIXEL SOLUTIONS WITH ROW IN-**

**JECTION.** The original 1-pixel theory has been reformulated for many pixels and solved numerically, almost exactly. Applicability to multiple-pixel charge-injection devices (CIDs) is supported by the consistency of the theory and comparison with measurements. Row-injection is only a small subset of possible multiple-pixel CID problems, but others may be relatively straightforward with the present calculations as an example. With these accurate results, approximations can be evaluated. 6 refs.

**095895 AUTOMATIC MEASUREMENT OF MINORITY CARRIER LIFETIMES IN SILICON FOR NONUNIFORM DOPED SAMPLES USING THE ZERBST METHOD.** One of the problems of automatically measuring lifetime using the Zerbst technique is the estimation of the total time required for measurement. The paper addresses this problem, and the proposed method is applicable to both uniformly and nonuniformly doped samples. This enables the data to be measured in a manner which ensures that noise free plots are obtained. (Author abstract) 35 refs.

**095896 LATTICE PARAMETER MEASUREMENT OF SUB-MICRON DEVICE STRUCTURES IN COMPOUND SEMICONDUCTORS VIA CONVERGENT-BEAM ELECTRON DIFFRACTION.** Dynamical diffraction effects prevent direct extraction of changes in the lattice parameter from convergent-beam electron diffraction (CBED) patterns which are obtained from high atomic number materials such as compound semiconductors. Therefore, in order to measure the relative lattice mismatch of a quaternary (InGaAsP) device structure grown on InP, we have opted to calibrate the relative position of CBED features with X-ray lattice parameter measurements which were obtained from planar quaternary layers grown on InP substrates. Three parameters from bright-field CBED patterns were measured as a function of the X-ray determined lattice mismatch in order to establish three separate calibration curves. CBED measurements taken from a device structure were found to produce similar values of lattice mismatch when interpreted using the calibration curves. The close correspondence of these three values of the lattice mismatch  $((4.541 \pm 2.119) \times 10^{-4})$ ,  $(5.158 \pm 2.881) \times 10^{-4}$ , and  $(4.819 \pm 4.021) \times 10^{-4}$ , enhances the credibility of this approach for the characterization of sub-micron device structures. (Edited author abstract) 9 refs.

**095897 ELECTRICAL MEASUREMENTS OF DEVICES FABRICATED IN PULSED ARC LAMP RAPID-ZONE-RECRYSTALLIZED SILICON ON INSULATOR.** A seeded polysilicon-coated sample is rapidly preheated and scanned by a linear translation table under the zone; speed is of the order of 35 cm/s. The lamp energy is collimated by a plate optic to a 0.5-mm line

with 8-kW-cm<sup>-2</sup> power density. A single lamp pulse melts the top film and the sample then cools by radiation. The sample is above room temperature for less than 15 s. Three-inch Si wafers with 0.5- $\mu$ m-thick seeded SOI islands (50  $\mu$ m by 2.5 cm) were prepared by this method. MOSFETs, resistors, capacitors, lateral junction diodes, Schottky diodes, and MESFETs were fabricated; standard CMOS LOCOS process technology was used. Measurements reveal electron mobilities averaging 670 cm<sup>2</sup>-V-s in implanted channels 915% higher than in bulk monitor samples). Unpassivated backchannel leakage averaged 80 nA- $\mu$ m<sup>-2</sup>. Minority-carrier lifetimes over 10  $\mu$ s (comparable to line e-beam recrystallized samples) exceed the values commonly seen in ZMR material. The electrical results confirm the material quality suggested by scanning electron microscopy, transmission electron microscopy, and Nomarski observations. The process, with significantly higher throughput than one requiring a vacuum, has application to high-speed, dense, radiation-hard CMOS. 4 refs.

**095898 CHANNEL-LENGTH MEASUREMENT TECHNIQUE BASED ON A FLOATING-GATE DEVICE.** By measuring the threshold voltage of the structure for several drawn channel lengths,  $\Delta L$  is extracted. This technique is the translation of a capacitance measurement into a threshold measurement and as such is accurate and simple to perform. Since the technique does not involve a current flow through the transistor under test, it is especially advantageous for  $L_{eff}$  measurements on lightly-doped drain (LDD) and double-diffused drain (DDD) short-channel devices. 5 refs.

**Metallizing** See Also ELECTRIC CONTACTS, OHMIC—Manufacture.

**095900 SELF-ALIGNED COBALT DISILICIDE FOR GATE AND INTERCONNECTION AND CONTACTS TO SHALLOW JUNCTIONS.** A novel gate and interconnection and contact metallization technology that uses cobalt disilicide for both purposes is presented. Cobalt disilicide, with a thin polycrystalline film resistivity of 15-20  $\mu\Omega$ -cm, offers a 0.5-1- $\Omega/\square$  sheet resistance at the gate level in the silicide/polysilicon gate metal scheme. It also offers an excellent contact metallization scheme to shallow junctions. The scheme described utilizes self-aligned patterning features and low-temperature processing and shows stability up to 900°C. Various other features of the processing and characteristics of the silicide are presented. 28 refs.

**095901 METALLURGICAL TOPICS IN SILICON DEVICE INTERCONNECTIONS: STRESSES.** Some of the problems encountered in thin film metallizations are presented in chronological order with references given to the literature dealing with a variety of topics, such as e.g. electromigration. The material which follows has been limited to the issue of stresses in thin films. A consideration of the general equilibrium of forces between films and substrates is extended to the measurement of stresses in uniform continuous films. In practical conditions with edges at via holes and along narrow conductors the stress distributions become more complicated. Intrinsic and extrinsic stresses are discussed with respect to both their origin and to what they mean for technological applications. Stress relaxation causes the formation of hillocks and holes. The implications of stresses with respect to adhesion and other practical effects are reviewed. (Edited author abstract) 107 refs.

**095903 EFFECT OF LOW-ENERGY ELECTRON IRRADIATION IN A SCANNING ELECTRON MICROSCOPE ON THE PARAMETERS OF SEMICONDUCTOR DEVICES.** The increase in the complexity and degree of integration of integrated circuits has made exceedingly urgent the problem of measurements of their elements, monitoring of the functioning, and analysis of faults by the methods of scanning electron microscopy (SEM). It is well known, however, that irradiation with electrons can substantially alter then electrophysical parameters of the elements and circuits. In this work the effect of irradiation in SEM on the parameters of some types of semiconductor devices is studied, and it is shown that even very sparing observation regimes can give rise to significant degradation of the parameters, the possibility of which must be taken into account in the analysis of results obtained with the help of SEM, and therefore SEM in application to semiconductor devices must in the general case be regarded as a destructive method. 9 refs.

**095905 ANISOTROPY OF THE ENERGY SPECTRUM OF REFLECTED ELECTRONS IN A HETEROTRANSITION.** Scanning electron microscopy (SEM) is an effective method for testing the geometrical and electrophysical parameters of semiconductor instruments of microelectronics and electrooptics. Development of new types of instruments with characteristic dimensions of the working regions up to several dozen angstroms requires development of new research methods based on mathematical processing of SEM signals with consideration of their distribution function in the investigated subject. For this purpose, the physical mechanism of formation of signals must be determined in turn and an adequate theoretical model must be created. This work examines the experimentally detected effect of anisotropy of the energy spectrum of reflected electrons (RE) near a heteroboundary when investigating heterostructures in SEM. A simple theoretical model, which agrees well with the experimental data, is proposed to explain the effect. (Author abstract) 4 refs.

**095906 ELECTRON-ACOUSTIC MICROSCOPIC STUDY ON DISLOCATION LINES IN THE BASE REGION OF npn Si-Tr.** Using an npn Si-Tr chip, bias voltage was applied between the collector and the base for in situ observation of SEM and electron-acoustic microscopy (EAM) in the same area. The results disclosed the following. (1) The contrast of electron acoustic image (EAI) of EAM varied with the bias conditions. (2) Dislocation lines were observed in the base region but not in the emitter region. (3) The dislocation lines in the EAI were not observed at bias voltage of 0 v but appeared at 0.4 V to the collector. (4) By using at acceleration voltage of 30 kV and Si as a specimen, the observation depth by EAM was about 10  $\mu$ m. EAM study of another type of Tr chips was also undertaken. (Author abstract) 14 refs.

## Microstructure

**095907 INFLUENCE OF DIFFERENT SEM PARAMETERS ON CD MEASUREMENT RESULTS.** The increasing complexity and the resulting reduction in feature dimensions mean that the already wide field of application of a Scanning Electron Microscope (SEM) is extended to that of metrology. In many cases, due to its higher lateral resolution and the increased depth of focus, Critical dimension (CD) data can only be acquired using a SEM instead of optical systems. The correct evaluation of the obtained results requires a detailed knowledge about the influence of different SEM parameters, such as primary electron (PE) energy, beam diameter, focus, etc., on the video profiles. Up to now, the complexity of the profile variations due to a change in SEM parameters do not allow a fast and convenient compensation by the software. This makes it necessary to calibrate the system after a variation of SEM settings. (Author abstract) 4 refs.

**095912 CRITICAL PLASMONS OF A QUASIPERIODIC SEMICONDUCTOR SUPERLATTICE.** Based on a versatile model, plasma excitations of the quasiperiodic semiconductor superlattice are studied through the rational approximation method. An universal condition is obtained. Thus not only a series of results in several references can be reproduced easily, but also the dispersion relations of the second type of quasiperiodic semiconductor superlattice and quasiperiodic superlattice of the II-VI compounds can be determined. A method is suggested to calculate the surface plasma modes of the semi-infinite quasiperiodic superlattice. (Author abstract) 11 refs. In Chinese.

**095913 PHYSICS AND MODELING OF SUBMICRON SEMICONDUCTOR DEVICES.** The modeling of semiconductor devices almost always is done in order to try to explain or understand the underlying physics that produces an observed set of terminal characteristics. Thus, the model must incorporate the relevant physical processes, and good model development must rely on both intuition (of the theoretician) and experimental observations. We discuss the approaches used in developing

models and the special problems that arise in submicron semiconductor devices. (Edited author abstract) 15 refs.

**095914 STUDY OF SECONDARY EMISSION 1/f NOISE.** The secondary emission 1/f noise observed by Schwantes and Van der Ziel has been investigated in more detail. The new experiments were prompted by Van der Ziel's application of Handel's theory to Schwantes's 1960 secondary emission noise data. To that end we measured the spectrum  $S_{I_a}(f)$  versus  $(V_a - V_d)^{3/2}$  at constant current  $I_a$  and constant  $\delta$  and the noise spectrum versus  $I_a \delta^2$  at constant voltage  $(V_a - V_d)$  both for a large resistance  $R_c$  in the cathode lead. The results show good agreement with Handel's prediction, i.e. Handel's expression for the Hooke parameter  $\alpha_H$  is here verified. We finally discuss the meaning of these results and show that the Bremsstrahlung hypothesis can explain most of the data. (Author abstract) 5 refs.

**095915 VELOCITY FLUCTUATION NOISE MEASUREMENTS ON AlGaAs-GaAs INTERFACES.** Experiments performed to determine the dc, ac, and noise properties in the hot-electron regime of AlGaAs-GaAs heterojunction interfaces are discussed. With the use of noise temperature data, the diffusion coefficient can be determined as a function of electric field for transport parallel to the AlGaAs-GaAs interface. Two device structures with different characteristics, such as length, fraction of aluminum content, sheet-carrier concentration, etc., are used in the experiments. The experimental results are attributed to the field-dependent charge-transport properties of the quasi-two-dimensional electron gas formed at the interface. 14 refs.

**095917 UNIFIED PRESENTATION OF 1/F NOISE IN ELECTRON DEVICES: FUNDAMENTAL 1/F NOISE SOURCES.** 1/f noise in semiconductors, semiconductor devices, and collision-free devices (like vacuum tubes) is presented from a unified point of view, using an extended version of the F. N. Hooke equation (Physica, vol. 83b, p. 9, 1976), which is generalized to all collision-dominated systems involving mobility, diffusion, and cross-section fluctuations. It also applies to collision-free processes involving vacuum tubes, Schottky barrier diodes operating in the thermionic mode, and in devices such as p-i-n diodes in which collision processes are not the

determining factor. A generalized schematic is given for expressing the noise spectrum  $S_I(f)$  in the external circuit in terms of distributed noise sources of the nonuniform devices in terms of  $\alpha_H$ , so the latter can be determined from the former. It is then found that the Hooke parameter,  $\alpha_H$ , introduced by this equation can be used as a general measure of the noisiness of a system or device. Several cases in which the noise does not obey the quantum 1/f noise theory are discussed. Measurements on many different devices are examined, and an attempt is made to correlate measured values of the Hooke parameter with the values calculated from P. H. Handel's quantum theory of 1/f noise (1975, 1980). 97 refs.

**095918 NEW STEP IMPACT ELECTROLUMINESCENT DEVICES.** The step impact electroluminescent devices (SIED) and the multistep photon amplifier converted (SPAC) are proposed. The devices are a multilayered heterojunction structures in which the acceleration and collision excitation processes are spatially separated and permits independent optimization of each function in different materials. In collision excitation region, ballistic electrons excite the rare earth ions by direct impact. By changing conduction band step  $\Delta E_c$  we can tune up the energy of excited electrons to the resonance condition of a particular excited state of  $RE^{3+}$  ions. The emission from the rare earth ions with transition wavelength shorter than semiconductor's band edge emission can be generated. The emission will contain narrow lines with gradual change in wavelength with temperature. The advantages of the new devices and excitation mechanism are discussed in detail. (Edited author abstract) 42 refs.

**095926 FOCUSED-ION-BEAM FUSE CUTTING FOR REDUNDANCY TECHNOLOGY.** Fuse cutting with focused ion beams to activate redundancy circuits is proposed, and experiments are reported that verify its potential usefulness. Aluminum fuses covered with a thin passivation layer, which are difficult to cut by conventional laser-beam technology due to the material's high reflectivity, were cut in 5 s. Ga ion beams with 30-kV acceleration voltage, 0.8- $\mu$ m beam diameter, and 0.3-A/cm<sup>2</sup> current density were used. No change in device properties due to focused-ion-beam irradiation was observed unless the focused ion beams were incident directly on the device. It is concluded that the focused-ion-beam programming technique will be useful for redundancy circuit programming. 13 refs.

**Protection**

**095927 SEMICONDUCTOR CHIP PROTECTION - PART 2.** The previous issue in this series introduced the

United States semiconductor chip protection legislation (SCAPA) and discussed what works are eligible for protection, the rights granted by registration and ownership. This issue deals with how a mask work is protected, including the application and the deposit requirements. (Author abstract)

Burshtein, S. *Eng Dig (Toronto)* v 33 n 8 Sep 1987 p 28-29.

#### 095928 SEMICONDUCTOR CHIP PROTECTION

- PART 1. In today's computer age, one of the most valuable forms of intellectual property is the right to prohibit reproduction of a semiconductor chip. Computers were originally developed without semiconductor chips. With the miniaturization of circuits and the development of semiconductor chips, computers have become more valuable tools. Behind the manufacture of any chip there is an extremely elaborate 3D design. The first step in the production of a chip is the making of 'masks' that are in the nature of photographic templates and are used in a way somewhat reminiscent of a photographic process to etch or deposit microscopic circuits and components on a silicon chip. A different mask is needed to produce each layer making up the chip. (Author abstract)

Burshtein, Sheldon (Blake, Cassels & Graydon, Toronto, Ont, Can). *Eng Dig (Toronto)* v 33 n 7 Aug 1987 p 10-11.

#### 095929 SEMICONDUCTOR CHIP PROTECTION

- PART 4. In the previous parts in this series the protection afforded by the US semiconductor chip protection legislation (SCPA) was discussed. This concluding part deals with the national scope of the legislation and in what circumstances it may extend to Canadians. Also discussed is the state of Canada's progress in connection with mask work protection at the time of writing. (Author abstract)

095930 RADIATION HARD CIRCUITS. The development of basic device technologies with a high degree of tolerance to various radiation environments is essential for many new strategic and space-based military systems. The basic mechanisms of radiation effects on Si and GaAs devices have been identified. Examples of how fabrication processes can be tailored to significantly improve the resistance of advanced silicon bipolar circuits to total ionizing dose and GaAs MESFET technology to transient ionizing radiation have been presented. 5 refs.

#### 095931 SIMULATION OF HEAVY CHARGED PARTICLE TRACKS USING FOCUSED LASER BEAMS.

A laboratory system utilizing a Q-switched Nd-doped YAG laser is used to simulate the ionization track produced as energetic heavy ions traverse a semiconductor device (resulting in single-event upset effects). Details of the optical design for producing the precisely focused spot, and the requirements for fast pulses, are described. The advantages and disadvantages of the use of this laboratory simulation are discussed. Laser tests on p-n diodes, p-n junctions, bipolar memories, and power MOSFETs are described and compared to high-energy particle test results. 14 refs.

#### 095932 ANGULAR DEPENDENCE OF CHARGE FUNNELING IN SI AND GAAS DEVICES. Charge collection and transient current measurements on n-type

GaAs and Si Schottky diodes bombarded with single alpha particles reveal a strong dependence on angle of incidence. Prompt recombination is evident in both materials. The magnitude of charge collected by funneling is proportional to the charge generated in the depletion region. An alternative interpretation of the data is that charge generated to a certain depth below the junction, proportional to the depletion width, is collected by funneling. The increased collection of charge with increasing angle appears to be due to a longer collection time. These measurements indicate that dynamic processes occur during charge funneling which are not fully described by existing phenomenological models. 19 refs.

#### 095933 COMPARISON OF NEUTRON, PROTON AND GAMMA RAY EFFECTS IN SEMICONDUCTOR DEVICES.

Interest in proton radiation effects has intensified in recent years. A prime focus is the relationship between proton displacement and ionization effects and the separate consideration of neutron-induced displacement and gamma-ionization effects in TREE characterization. Recent work on proton and neutron displacement damage in silicon in terms of nonionizing energy loss has laid the groundwork for comparison of proton effects with the TREE database. Device radiation susceptibilities in neutron and gamma environments are summarized. Proton interactions in silicon devices are presented in terms of dose deposition and nonionizing energy loss. This leads to a neutron-proton damage equivalence factor and enables the development of a simple correspondence. The device susceptibility charts are then combined so that both displacement damage and ionization damage can be schematically examined relative to proton dose. These susceptibility charts demonstrate the dominance of ionization effects for damage in a proton environment for silicon microcircuit technologies. This approach is presented as a means of interpreting effects for both proton exposures and TREE simulators. It is concluded that TREE characterization can be used as a good first-order estimate of proton damage effects. 25 refs.

#### Reliability See Also COMMUNICATION SATELLITES—Components; COMMUNICATION SATELLITES—Reliability; SEMICONDUCTOR DIODES, LIGHT EMITTING—Testing.

#### 095934 RELIABILITY DESIGN OF SEMICONDUCTOR DEVICES FOR CS-3 COMMUNICATION SATELLITE.

Semiconductor devices used in the CS-3 communication satellite are required to have higher reliability than the devices in the CS-2 satellite, because of the long-life and large communication capacity design of the CS-3 satellite. This paper presents the technologies for improving the reliability of the semiconductor devices used in the CS-3 transponders. Lifetime lengthening for GaAs power MESFETs is accomplished by applying Ti/Al Schottky gate metallization. Long-term stress testings of a large number of samples were undergone. Radiation hardness of Si devices is assured through selection. (Author abstract) In Japanese. 6 refs.

#### 095935 MECHANICAL DECAPSULATION TECHNIQUE FOR EPOXIDE-PACKAGED SEMICONDUCTOR COMPONENTS.

A novel mechanical technique for decapsulating plastic semiconductor components has been developed. The technique is extremely easy to use, has a high success rate, and is superior in all respects to previously-described mechanical techniques

which give inconsistent results. A significant advantage over alternative chemical techniques is that corrosion products on the die surface are retained. This paper describes the new technique and shows examples of new and corroded components that have been successfully decapsulated. (Author abstract) 7 refs.

#### 095936 EARLY LIFE FAILURES.

Device failures can be classified as event-dependent, time-dependent, and a combination of the two, event/time-dependent failures. Early life failure are dominated by event-dependent failures, i.e. Electrostatic Discharge (ESD) failures, and mechanical failures (bonds, cracks, etc.) that result from a stress event. Test and failure analysis results supporting the above are reviewed. This paper was presented at the 1985 Semiconductor Device Reliability North Atlantic Treaty Organization (NATO) Workshop. (Edited author abstract) 10 refs.

#### 095937 SUBSURFACE BURNOUT MECHANISMS IN GALLIUM ARSENIDE (GaAs) ELECTRONIC DEVICES.

Subsurface burnout has been observed in GaAs power field-effect transistors (FET), GaAs planar transferred electron devices (TED) biased at sufficiently high voltages<sup>7,8</sup> and in some cases when GaAs FETs<sup>9</sup> and modulation doped FETs (MODFETs)<sup>10</sup> are irradiated with alpha particles. This paper attempts to access the present state of theoretical models to explain the physical mechanisms responsible for subsurface burnout in these devices with the aid of recent experimental results. The results of the work should assist in the creation of more reliable devices with greater radiation hardness. (Edited author abstract). 55 Refs.

#### 095938 YIELD IMPLICATIONS AND SCALING LAWS FOR SUBMICROMETER DEVICES.

Yield scaling laws are developed that are applicable to VLSI (very large-scale integration) devices with features of minimum dimension smaller than that at which the defect-size probability density function peaks. Expressions for the fault-probability kernel of reduced-size devices are derived in terms of the full-size or prototype device. The role of the defect-size probability density function with respect to the average fault probability is explained and expressions for it are developed. The ensuing scaling laws are utilized to obtain expressions for the expected number of faults, and then applied to the evaluation of the yield for several different cases. The implications of the results for yield and productivity are examined. 19 refs.

## Seals

**095940 EXISTENCE OF PLATING LAYER AT THE SURFACE AND ITS EFFECTS ON JOINING CHARACTERISTICS: MICRO-PARALLEL SEAM JOINING AND DEVELOPMENT OF JOINING EQUIPMENT (1ST REPORT).** The authors studied micro-parallel seam joining (MPSJ) used for the hermetic seal of ceramic packages for semiconductor devices. Attention was paid to the relationship between plated materials on the package and lid and its seam joining characteristics. It is necessary to use Fe-Ni-Co Kovar as a lid material because it has a similar thermal expansion coefficient to the ceramic substrate ( $\text{Al}_2\text{O}_3$ ). The lid and seal frame are joined by brazing under pressure of the plating material. (Edited author abstract) 12 refs.

**095941 ANALYSIS OF ATOMIC SCALE STRUCTURE OF  $\text{Si}/\text{SiO}_2$  INTERFACE BY COMPUTER SIMULATION.** Atomic scale structure of  $\text{Si}/\text{SiO}_2$  interface has been constructed using crystal models. By assuming an appropriate interatomic potential, various structural properties have been deduced by computer simulation. The results of the calculation have shown a reasonable coincidence with various experimental results reported so far. A detailed understanding of the atomic scale structure of the  $\text{Si}/\text{SiO}_2$  interface has been obtained. (Author abstract). In Japanese. 39 refs.

**095942 QUANTITATIVE MODELING OF  $\text{Si}/\text{SiO}_2$  INTERFACE FIXED CHARGE: I. EXPERIMENTAL RESULTS.** Fixed-oxide charge density ( $N_f$ ) at the  $\text{Si}/\text{SiO}_2$  interface for (100) and (111) wafers oxidized in dry  $\text{O}_2$  and annealed in argon has been studied as a function of the argon anneal temperature. In contrast to previous qualitative results, the annealed  $N_f$  value was found to be dependent on the anneal temperature. Wafers thermally cycled in argon showed reproducible, steady-state  $N_f$  values, which also cycled with temperature. These results may indicate that the residual charge densities after annealing represent an equilibrium state of the  $\text{Si}/\text{SiO}_2$  interface. The dependence of  $N_f$  on annealing time was found to be an exponential decay with a thermally activated time constant. As-grown fixed oxide charge  $N_f$  has also been characterized as a function of oxidation temperature and oxygen partial pressure. (Edited author abstract) 33 refs.

**095943 QUANTITATIVE MODELING OF  $\text{Si}/\text{SiO}_2$  INTERFACE FIXED CHARGE: II. PHYSICAL MODELING.** The fixed-oxide charge density of  $N_f$  at the  $\text{Si}/\text{SiO}_2$  interface has been studied as a function of process variables. The process parameters used were temperature, time, ambient, and oxidation cycle. To explain the experimental data, it is postulated that oxide charges are located at specific interface sites, perhaps, the kinks and steps thought to be associated with the oxidation process. It is also postulated that silicon interstitials generated at the  $\text{Si}/\text{SiO}_2$  interface recombine with kinks and steps via a monatomic surface regrowth process. Using these concepts, the process dependence of oxide charges is modeled quantitatively in oxidizing and nonoxidizing ambients. The model, which is physically based, can be

used to predict  $N_f$  in the temperature range of 700°-1100°C, and in the oxidant partial-pressure range of 0-100%  $\text{O}_2$  in Ar. (Edited author abstract) 40 refs.

Akinwande, A.I. (Stanford Univ, Stanford, CA, USA); Plummer, J.D. *J Electrochem Soc* v 134 n 10 Oct 1987 p 2573-2580.

**095944 PROCESS DEPENDENCE OF THE  $\text{Si}-\text{SiO}_2$  INTERFACE TRAP DENSITY FOR THIN OXIDES.** The intrinsic interface traps associated with thin (approx. 100-400 Å) thermal oxides on silicon have been characterized with reference to different oxidation and annealing conditions using the quasi-static capacitance-voltage technique. For unannealed oxides, the interface trap distribution profiles exhibit peak structures in the lower half of silicon bandgap. A systematic dependence of the interface trap density on the oxidation variables was observed. A lower midgap density results for higher oxidation temperature, lower oxygen partial pressure in the ambient, and thicker oxide. For thin oxides, postoxidation annealing in nitrogen may decrease or increase the interface trap density depending on the anneal temperature. (Edited author abstract) 29 refs.

**095945 SUB-BAND STRUCTURE FOR ELECTRONS AND HOLES IN INVERSION AND ACCUMULATION LAYERS AT THE  $\text{InGaAs-InP}$  INTERFACE.** In this paper we present the results of self-consistent sub-band calculations for the modulation-doped  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As-InP}$  interface. We give results both for the 2D EG and for the 2D HG and in both cases we consider n-type and p-type background doping in the  $\text{InGaAs}$ . The treatment of the 2D hole gas is more complicated because of the degeneracy of the bulk valence band. We use the  $4 \times 4$  Luttinger Hamiltonian to describe the coupling between heavy-hole and light-hole bands. 30 refs.

Ekenberg, U. (Dep of Theoretical Physics, Oxford, Engl). *Semicond Sci Technol* v 2 n 12 Dec 1987 p 802-808.

**095946 INTERFACE ANALYSIS OF  $\text{Al}_2\text{O}_3/\text{InP}$  STRUCTURE PREPARED BY MOLECULAR BEAM DEPOSITION.** We have applied disorder-sensitive high-energy ion scattering together with the C-V method to an interface study of  $\text{Al}_2\text{O}_3/\text{InP}$ , which was prepared with well-controlled molecular beam deposition. Low interface state densities (the minimum value near the midgap is approximately  $1 \times 10^{11} \text{ cm}^{-2} \text{ eV}^{-1}$ ) have been obtained in the present work. Measurements of the interface disorder for these samples suggest that there is a correlation between the interface state density and the interface disorder. It is necessary to lower the interface disorder to obtain low interface state densities. (Author abstract) 16 refs.

**095947 SURFACE ELECTROSTATIC OSCILLATIONS AT A MAGNETIZED SEMICONDUCTOR-DIELECTRIC BOUNDARY.** The spectrum of resonant frequencies of surface oscillations on a semiconductor-dielectric boundary is found for the case of arbitrary wave propagation direction relative to a constant external magnetic field, oriented parallel to the plane separating the media. Conditions are found under which solutions of the surface wave type are absent, i.e., a gap appears in the surface oscillation resonant frequency spectrum. It is shown that presence of this gap correspond to nontransmission of surface oscillations within a definite angular sector. The dependence of gap position and width on the magnitude of the external magnetic field and the semiconductor and dielectric parameters is found. (Author abstract) 10 refs.

Beletskii, N.N. (Acad of Sciences of the Ukrainian SSR, USSR); Gasan, E.A.; Yakovenko, V.M. *Radiophys Quantum Electron* v 30 n 3 Mar 1987 p 335-340.

**095948 THEORY OF  $1/f$  NOISE IN SEMICONDUCTOR-DIELECTRIC STRUCTURES WITH AN INVERSION CHANNEL AT THE INTERFACE.** One of the best known models for  $1/f$  noise is that of McWhorter, according to which this noise is due to the randomness of the processes of electron and hole exchange between a bulk semiconductor and traps located in an oxide film at its surface. Despite the physical simplicity and naturalness of the McWhorter model, up to the present time there has been no correct calculation of the spectral density of the noise which occurs within the framework of this model. Here the errors tolerated in the literature are not of a partial nature: The very widely accepted scheme for calculating  $1/f$  noise is invalid in principle. In the present work, based on the McWhorter model, a systematic calculation of the spectral density of the fluctuations in the number of free carriers in an inversion channel at a semiconductor-dielectric boundary is carried out. 22 refs.

**095949 XPS STUDY OF THE PASSIVATING OXIDE LAYER PRODUCED ON  $\text{GaAs}$  (001) SUBSTRATE BY HEATING IN AIR ABOVE 200°C.** The passivating oxide layer resulting from a high-temperature (250°C in air)  $\text{GaAs}$  substrate preparation procedure has been analysed by X-ray photoelectron spectroscopy. It is shown that the protective film obtained from heating a semi-insulating substrate in clean air to 250°C is mainly gallium oxide whereas it is an arsenic-rich mixture of As and Ga oxides after the standard preparation procedure. At this temperature, the oxidation steady-state conditions are reached after 5 minutes of heating. The higher the passivating temperature, the lower the arsenic content of the oxide layer. (Author abstract) 12 refs.

**095950 SUB-BAND-GAP SURFACE PHOTOVOLTAGE IN  $\text{Si}/\text{SiO}_2$  STRUCTURES WITH QUASI-CONTINUOUSLY DISTRIBUTED INTERFACE TRAPS AND A DEEP IN LEVEL IN THE SEMICONDUCTOR BULK.** Computer simulation studies of sub-band-gap surface photovoltage (SPV) spectra of  $\text{Si}/\text{SiO}_2$  structures with optically active quasi-continuously distributed interface traps (ITs) and an In deep bulk level (DBL) are presented. The calculations have been carried out at  $T=93 \text{ K}$  for a variety of exciting light intensities. In order to separate the IT and DBL contributions to the SPV spectra, two  $\text{Si}/\text{SiO}_2$  structures have been considered separately. The substrate in the first structure contains only shallow B acceptors and that in the second structure only deep In acceptors. In the  $(\text{Si:B})/\text{SiO}_2$  case the SPV spectrum has been explained in terms of a proper model for the IT optical behavior. The theoretical results have been experimentally verified and the IT photoionization cross-sections have been determined. In the  $(\text{Si:In})/\text{SiO}_2$  case the conditions have been found under which both IT and In DBL influence the SPV spectra behavior. The possibility of determining basic DBL optical parameters has been shown. (Author abstract) 21 refs.

**095952 InGaAs/Si<sub>3</sub>N<sub>4</sub> INTERFACE OBTAINED IN ULTRAHIGH VACUUM MULTIPOLAR PLASMA: IN-SITU CONTROL BY ELLIPSOMETRY AND ELECTRICAL CHARACTERIZATION.** A multipolar plasma passivation scheme controlled by in-situ ellipsometry has been developed to produce a high electrical quality InGaAs/Si<sub>3</sub>N<sub>4</sub> interface. We have demonstrated the possibility to remove all native oxides at the InGaAs surface by heating the sample at 240°C, then using the action of a multipolar H<sub>2</sub> plasma at 185°C, without optical degradation of the surface. The passivation by a native nitride layer is then performed using a N<sub>2</sub> plasma, and Si<sub>3</sub>N<sub>4</sub> is deposited. The treatment induces a reduction of the density of interface states N<sub>SS</sub>(E), and also a change of the nature of these interface states as shown by a reduction in the capture cross section  $\sigma_n$ (E). (Author abstract) 14 refs.

**095953 PHOTOLUMINESCENCE TRANSIENT RESPONSE AS A TOOL TO 'TRACK' THE ORIGIN OF DRIFT PHENOMENA AT THE InP/INSULATOR INTERFACE.** We show that the shape of long-term photoluminescence (PL) transients from InP crystal is strongly affected by charge exchange processes between the semiconductor bands and slow traps situated at or near to the semiconductor surface. We show that the PL transients depend on chemical treatments of the surface and on the insulating layer deposition. We propose an electrical model of InP surface (interface) which explains the obtained experimental results. (Author abstract) 12 refs.

**095954 TIME-DEPENDENT RESPONSE OF INTERFACE STATES DETERMINED BY USING DIFFERENTIAL ISOTHERMAL TRANSIENT SPECTROSCOPY.** A method based on the differential analysis of the isothermal transients is proposed to study the dynamical properties of the charging and discharging of interface states, and several possible ties of using this method are shown. The results obtained in SiO<sub>2</sub>/Si and Si<sub>3</sub>N<sub>4</sub>/SiO<sub>2</sub>/Si samples are in agreement with the existence of a spatial and energy distribution of interface states within the insulator. From the experimental data, the concentration of traps within the insulator at 35 A is estimated to be  $5 \times 10^9 \text{ cm}^{-2} \text{ eV}^{-1}$ , with a tunneling cross section about  $10^{-19} \text{ cm}^2$ , at  $E_c \approx 0.2 \text{ eV}$ . (Author abstract) 8 refs.

**095955 LOW-TEMPERATURE ESR STUDY OF P<sub>b0</sub> DEFECTS RESIDING IN THE (111) Si/NATIVE OXIDE INTERFACE.** A K-band electron spin resonance (ESR) study of the (111) Si/native SiO<sub>2</sub> structure has been carried out in the temperature range  $2.4 < T < 30 \text{ K}$ . The ESR signal of the interfacial [111]P<sub>b0</sub> center was observed, exhibiting in general similar properties to the well-documented [111]P<sub>b0</sub> signal observed on firmly thermally-oxidized (TO) Si. Apart from the [111]P<sub>b0</sub>

center, also the signals of the P<sub>b0</sub> defects with their dangling orbital parallel to [111], [111] or [111] have been observed; as yet, these signals have not been observed; as yet, these signals have not been observed on TO structures. The saturation behavior has been examined showing the P<sub>b0</sub> Si/native oxide interface center to be much less saturable than the P<sub>b0</sub> in TO structures. The observations are related to the particular physicochemical interface structure. (Author abstract) 16 refs.

**095956 STUDY OF METAL-SEMICONDUCTOR INTERFACE STATES USING DEEP LEVEL TRANSIENT SPECTROSCOPY.** This paper describes the principle of the determination of interface-state parameters by deep level transient spectroscopy (DLTS) and presents a new, simple and exact method to discriminate the DLTS signal due to the emission from interface states from that from bulk traps. The n-type Au-GaAs and Cr-GaAs interfaces have been investigated by the technique. The results obtained in the investigation have revealed the dependences of the energy position, density and capture cross section for the interface states on the metal deposited onto the semiconductor surface, which is consistent with the theoretical prediction by Yndurain and the experimental results obtained by other authors. (Author abstract) 17 refs.

**095957 ON THE FERMIL LEVEL PINNING AT Ge/GaAs(110) INTERFACE.** By semi-empirical TB method and saturated slab model, the electronic states on the GaAs(110) surface adsorbed by Ge atoms in different coverages have been calculated. Combining with previous theoretical and experimental studies, an idea on the problem of Fermi level pinning on the Ge/GaAs(110) interface is suggested. (Author abstract) 8 refs. In Chinese.

**095958 INTERFACIAL PROPERTIES OF METAL OVERLAYERS ON III-V COMPOUNDS.** This paper gives a short review of the interfacial properties of a few metal/III-V systems prepared under atomically clean conditions. The author focuses on a few representative interfacial layers with distinctly different electronic structural properties. A description is given of the Cr/InP (110), In/GaAs (110), and Yb/GaAs (110) interfaces. It is shown that a detailed understanding can now be obtained on an atomic scale about both the interfacial growth and the compositions of reaction products. 25 refs.

**095959 CHARACTERIZATION OF SEMICONDUCTOR INTERFACES WITH SYNCHROTRON RADIATION.** Photoemission spectroscopy and other techniques based on synchrotron radiation are extensively used to investigate the formation of metal-semiconductor interfaces, heterojunction interfaces and gas chemisorption on semiconductor surfaces. We review the present status and the predicted future development of this active area of research. In particular, we discuss the interplay of factors such as interface defects and metal-induced gap states in the establishment of Schottky barriers and of heterojunction band discontinuities. We also discuss the future use of photoemission in an 'integrated' production-characterization technology for solid-state devices, based on synchrotron radiation. Finally, we comment on the predicted impact of the new, ultrabright synchrotron

radiation sources under development at Berkeley and Trieste. (Author abstract) 31 refs.

**095965 TLM MODELING OF SOLDER JOINTS IN SEMICONDUCTOR DEVICES.** The transmission-line matrix (TLM) is used to model heat flow in semiconductor devices. Unlike some other numerical methods, a sense of the physical nature of the problem is retained and irregular boundaries, inhomogeneities, and temperature-dependent thermal parameters can be easily incorporated. The inclusion of a layer of solder between a device and its package has a substantial influence on the temperature distribution. The effects of solder joint perfection are investigated theoretically, and the extent to which topographical methods such as infrared thermal imaging can give useful experimental results is indicated. 18 refs.

**Space Charge**

**095966 SPACE CHARGE EFFECTS IN RESONANT TUNNELING.** The effect of space charge accumulation in resonant tunneling devices is investigated. It is shown that the resonant current through a symmetric double-barrier device flows immediately after opening the resonant tunneling channel and does not require an exponentially long time to reach its steady-state value. It is also shown that space charge effects increase the width of the resonant peak in the I-V characteristic of a double-barrier device which tends to reduce the magnitude of the negative differential resistance. (Author abstract) 14 refs.

**095967 ON THE IMPEDANCE ASSOCIATED WITH ELECTRON-HOLE RECOMBINATION IN THE SPACE CHARGE LAYER OF AN ILLUMINATED SEMICONDUCTOR/ELECTROLYTE INTERFACE.** The impedance associated with recombination of free electrons and freeholes in the space charge layer has been calculated. It has been shown that this impedance corresponds to a parallel-equivalent circuit of a capacitance and a resistance in parallel with the space charge layer capacitance. It has been calculated that the recombination capacitance has almost the same voltage dependence as the space charge layer capacitance, and that the recombination resistance is inversely proportional to the recombination rate in the space charge layer. The impedance associated with recombination in the space-charge layer has been compared with the surface recombination impedance and with experimental results obtained at illuminated GaAs electrodes. (Author abstract) 17 refs.

**095968 RAMAN SCATTERING IN-DEPTH EVALUATION OF RECRYSTALLIZED SILICON-OXIDE USING DIFFERENT WAVELENGTH EXCITATION.** Recrystallized silicon-on-oxide were ana-

lyzed by laser Raman scattering spectroscopy. By changing the excitation laser wavelength, the in-depth stress profile was obtained. The in-depth stress change was strongly dependent on recrystallization power. Recrystallized silicon structures were confirmed by cross sectional TEM observations. Dependent on recrystallization power, silicon film structures changed from small grain or small and large two grain layers to continuous large grain films. (Author abstract) 4 refs.

Kanamori, M. (NEC, Kanagawa, Jpn); Tsuya, H. *J Electron Mater* v 17 n 1 Jan 1988 p 33-37.

**095969 RAMAN MICROPROBE STUDY OF SILICON- AND GERMANIUM-ON-INSULATOR STRUCTURES.** A Raman microprobe has been used to detect the changes in crystallinity, stress and homogeneity of thin films of silicon-on-insulator and germanium-on-insulator (GOI) structures. Silicon films recrystallized with a graphite strip heater at a substrate temperature of 1200°C show little or no stress, but those recrystallized with a continuous wave laser at a substrate temperature of 500°C have a residual stress of  $4 \times 10^9$  dyn  $\text{cm}^{-2}$ . Some of the strip-heater-recrystallized samples consist of large crystals of different orientations. As-deposited GOI is found to be unstressed. (Author abstract) 9 refs.

**095970 COMPUTER SIMULATION AND EXPERIMENTAL OBSERVATION OF FEATURES AND STABILITY FOR FOUR KINDS OF STATIONARY DOMAINS IN TRANSFERRED ELECTRON DEVICES.** The features and the stability of four kinds of stationary domains in transferred electron devices have been investigated. Computer simulation and experimental observation are carried out. The four kinds of stationary domains are: (1) A domain is triggered near the cathode, and travels toward the anode where it is trapped as a stationary domain, (2) A domain is triggered directly near the anode where it grows without traveling, and then settles as a stationary domain, (3) A domain is triggered near the cathode; then because the bias voltage increases further, the domain extends over the notch near the cathode, and so a stationary domain occurs, and (4) A stationary domain is formed due to a large inhomogeneous active layer. The stability, the current drop, the dependence between frequency and negative resistance, and ability to a support a voltage of four kinds of stationary domain have also been studied. (Author abstract) 6 refs.

**095975 ELEMENTARY ELECTRONIC EXCITATIONS AT THE SURFACE OF A SEMICONDUCTOR SUPERLATTICE AND THEIR COUPLING TO EXTERNAL PROBES.** Advances in Molecular Beam Epitaxy (MBE) and other growth techniques over the last decade have made it possible to grow materials consisting of alternating layers of two or more semiconductors. The thickness of each layer can be varied from several Å to several hundred Å, and the sharpness of the interface is of the order of one atomic layer. The semiconductor materials chosen usually have a similar lattice constant but different electronic properties. GaAs and GaAlAs systems are the best known at the moment. Electrons are free to move in the plane of the layers but are localized in a given layer and can have a discrete energy spectrum. These discrete levels are called subbands. When the energy of the barrier is low and the barrier width is narrow, electrons can tunnel between different GaAs regions (quantum wells) and these discrete energy levels broaden to form minibands. A periodic array of layers is called a semiconductor superlattice. The study of the intrasubband plasma excitations in quantum wells and superlattices is carried out. 36 refs.

**095976 BINDING ENERGY OF HYDROGENIC IMPURITY IN QUANTUM WELL STRUCTURES.** We have studied the anisotropic effects on the hydrogenic impurity states in a quantum well. The variation of the binding energy of the ground state as a function of the well thickness for quantum wells with isotropic or anisotropic effective masses are calculated. The dependence of the longitudinal and transverse effective radii on the well size

and the mass ratio  $m_1/m_2$  is also discussed. A simple approximation method proposed recently by Lee and Mei is also used to study the binding energy of the hydrogenic impurity in the finite quantum well. (Author abstract) 17 refs.

**095977 SCANNING LOW ENERGY ELECTRON LOSS MICROSCOPY (SLEELM): Au ON Si.** High-resolution scanning low energy electron loss imaging of a well characterized system of Au on Si is demonstrated in reflection geometry at a primary electron energy  $E_p$  of 680 eV and spatial resolution of 3  $\mu$ m. Characteristic losses below 30 eV are chosen to examine the contrast between two regions (gold and silicon dominated) respectively. By differencing between a maximum in a loss intensity and an adjacent trough, high-quality Si images are obtained with contrast superior to  $L_{2,3}$  VV Auger electron images produced in comparable times. It should be noted that, in contrast to scanning Auger microscopy, the spatial resolution of SLEELM is limited only by the profile of the incident beam. An advantage of low electron energy loss imaging is that the depth resolution may be varied by altering the primary electron energy, with the possibility of bridging the gap between Auger microscopy and the X-ray microprobe analyser. Disadvantages of the technique lie in the weakness of the elastic backscattering which is essential to observe the losses in reflection geometry, and the possibility of overlapping low energy characteristic loss peaks. (Edited author abstract) 17 Refs.

**095978 MONTE CARLO SIMULATIONS OF REPEATED VELOCITY OVERSHOOT STRUCTURES.** We have performed self-consistent Monte Carlo simulations on repeated velocity overshoot structures. From our calculations, we may assess the potential of such structures to enhance the average drift velocity of electrons. We find that there is no enhancement for uniformly doped structures. For spike-doped structures there is a small enhancement, but this is gained at the expense of a drop in current density. In both structures the velocity enhancement is limited by intervalley scattering. (Author abstract) 5 Refs.

**095979 CONDUCTION AND CHARGE TRAPPING IN POLYSILICON-SILICON NITRIDE-OXIDE-SILICON STRUCTURES UNDER POSITIVE GATE BIAS.** Carrier conduction and trapping in silicon-nitride-oxide-silicon SNOS structures has been studied under positive gate bias using current-field (I vs. E) characteristics and flat-band voltage shift-fluence ( $\Delta V_{FB}$  vs. F) for structures with a thick bottom oxide (>100 angstrom). Under these conditions evidence is found of electrons tunneling from the Si through the bottom oxide, and holes injected from the gate moving through the nitride with recombination occurring in the nitride layer. Trapping of both electrons and holes is significant and the saturation value of the flat-band voltage shift is shown to depend parabolically on the thickness of the nitride layer. A simple two-carrier conduction model is proposed to explain the observed conduction and trapping characteristics. It is also shown that holes are the dominant conduction carriers in polysilicon-silicon nitride-silicon (SNS) structures under both positive and negative gate-bias conditions. 16 refs.

**095980 DETERMINATION OF CONCENTRATION OF SURFACE STATES AT THE ILLUMINATED SEMICONDUCTOR-ELECTROLYTE INTERFACE.** Surface states at the semiconductor-electrolyte interface under illumination have been determined. The faradaic reaction involved at the (CdTe and GaP) interface is the photo-electrochemical reduction of carbon dioxide to carbon monoxide in dimethylformamide-water mixtures. A new equivalent circuit has been proposed to account for the impedance data. Surface states act as faradaic mediators for the reduction of carbon dioxide. Surface state density at a given bias potential has been calculated to be of the order of  $10^{14}$  cm<sup>-2</sup>. Adsorbed ions induce surface states. Surface state density induced by tetraalkylammonium ions decrease with increase of alkyl chain length. The number of surface states increases with water concentration. (Edited author abstract) 35 refs.

**095989 MULTIPLE STEADY STATES IN ONE-DIMENSIONAL ELECTRODIFFUSION WITH LOCAL ELECTRONEUTRALITY.** This paper concerns itself with construction and study of multiple steady states, occurring in one-dimensional ambipolar electrodiffusion with local electroneutrality, constant and equal charge carrier mobilities in the absence of generation-recombination. Piecewise constant fixed charge density with four sign alterations is assumed. Multiple solution branches are constructed via a numerical and asymptotic solution of a system of nonlinear equations, resulting from an explicit integration of the appropriate boundary value problem. The parameter range in which multiplicity occurs is determined with the aid of asymptotic procedures. Existence of the appropriate multiple solutions follows from the Newton-Kantorovich Theorem. (Author abstract) 15 refs.

## Thermal Effects

**095992 ON A PETROV-GALERKIN METHOD FOR THE ELECTRICAL AND THERMAL BEHAVIOUR OF SEMICONDUCTOR DEVICES IN TWO DIMENSIONS.** We consider the equations governing the electrical and thermal behavior of a semiconductor device in two dimensions. A non-standard Petrov-Galerkin method is used to obtain a discretisation of the equations for stationary problems. The resulting scheme is a generalization to the two-dimensional case and to the full set of equations of the well-known Scharfetter-Gummel scheme, which is the most successful discretisation for one-dimensional problems. The dependent variables used are the carrier densities, the electrostatic potential and the absolute temperature. (Author abstract) 5 refs.

**095994 CURRENT TRANSPORT OVER PARABOLIC POTENTIAL BARRIERS IN SEMICONDUCTOR DEVICES.** Current transport over the potential barrier of an  $n^+-p-n^+$  structure is studied using the diffusion theory and the thermionic-diffusion theory of current transport. Thermionic emission over the barrier is shown to be the asymptotic isothermal diffusion current. The J-V characteristics are derived for both the diffusion and thermionic-diffusion models. In particular, when the Bethe and the thermionic-diffusion (T-D) models are compared, both with and without backscattering effects, it is seen that the T-D model with backscattering is preferable to the Bethe approach and requires a relatively lower dopant concentration to be applicable. It is shown that two characteristic velocities are needed for the transport analysis: an effective collection velocity to terminate the region in which current is driven by diffusion and an emission velocity associated with carrier injection beyond the potential energy maximum. For a typical situation, the emission velocity can be as much as a factor of four greater than the collection velocity, showing that the velocity of injected carriers beyond the maximum can appreciably exceed the scatter-limited velocity. 18 refs.

**095995 SIMULATIONS OF THE CURRENT-VOLTAGE CHARACTERISTICS OF SEMICONDUCTOR TUNNEL STRUCTURES.** A method of calculating the current-voltage characteristics of semiconductor devices in which the current is controlled by tunneling through a series of potential barriers is presented. Its predictive powers allow it to be used as a design aid for such devices. (Author abstract) 19 refs.

Davies, R.A. *GEC J Res* v 5 n 2 1987 p 65-75.

**095996 INDIRECT TUNNELING CAPACITY OF THE  $p-n$  JUNCTION OF THE NARROW BAND-GAP SEMICONDUCTORS.** The expression of the capacity caused by the indirect tunneling process is derived by using the detailed balance between the process of indirect tunneling via deep impurity level and the process of thermal excitation and trapping. This capacity appears only in a narrow range of bias voltage around zero bias voltage. The C-V characteristic is not the usual monotonous function of voltage, but has a maximum and negative values in a range of bias voltage. Numerical calculations are made. The shape of the calculated C-V curves is similar to that of the measured C-V curves obtained on the  $p-n$  junctions of narrow gap semiconductors  $Hg_{1-x}Cd_xTe$ . (Author abstract) 8 refs. In Chinese.

**095997 TUNNELING RESISTANCE AND MAGNETORESISTANCE OF  $Al-Oxide-Al$  TUNNEL JUNCTIONS.** The temperature and magnetic field dependence of the tunnel resistance ( $R_T$ ) of  $Al-O-Al$  junctions have been studied for temperatures below 4.2 K. It is demonstrated that below 2.0 K  $R_T$  increases suddenly

and shows a negative magnetoresistance. The magnitude of this increase depends on the absolute value of  $R_T$  and is the smaller the larger  $R_T$  is. The effect corresponds to the behavior of 'weak localization' in thin disordered metallic films. (Author abstract) 6 refs.

**095998 POSSIBILITY OF CREATING ANALOG AND DIGITAL INTEGRATED CIRCUITS USING THE DISCRETE, ONE-ELECTRON TUNNELING EFFECT.** It was shown previously that in tunneling junctions of small area between metals (or grown semiconductors) at low temperatures a new effect - discrete tunneling by isolated current carriers through the tunneling barrier - is observed. It has become worthwhile to evaluate the possibility of using the discrete, one-electron tunneling effect in microelectronics. It is the purpose of this paper to perform such a preliminary analysis by combining tunneling junctions of small area with resistors and capacitors, a whole series of devices can be created in which analog information is stored and/or processes as individual electrons, and these devices may exhibit exceptionally high values of the useful characteristics. 28 refs.

**095999 NEW SCATTERING-THEORETIC APPROACH TO ELASTIC ONE-ELECTRON TUNNELING THROUGH SPATIALLY LOCALIZED BARRIERS: APPLICATION TO SCANNING TUNNELING MICROSCOPY.** One-electron elastic tunneling through nonseparable, localized barriers is treated as a problem in Potential Scattering Theory, using the technique of localized Green functions. The method is illustrated by the calculation of the current in a model plano-spherical junction representative of the Scanning Tunneling Microscope whose lateral resolution is discussed. The new technique is applicable to several other localized barrier problems and allows one to test the accuracy of approximate, one-electron tunneling theories. (Author abstract) 13 refs.

**096002 MAGNETIC FIELD STUDIES OF NEGATIVE DIFFERENTIAL CONDUCTIVITY IN DOUBLE BARRIER RESONANT TUNNELLING STRUCTURES BASED ON  $n^+ \text{InP}/(\text{InGa})\text{As}$ .** Negative differential conductivity (NDC) with a peak valley ratio of 4.5:1 (4 K) and 2:1 (150 K) is observed in double barrier resonant tunnelling devices based on  $n^+ \text{InP}/(\text{InGa})\text{As}$ . A transverse magnetic field applied in the plane of the tunnelling barriers ( $J \perp B$ ) significantly changes the current-voltage characteristics and eliminates the NDC for fields above -10 T. This behaviour is explained qualitatively in terms of the effect of the magnetic vector potential on the tunnelling electrons. The magneto-oscillations in the tunnelling current for  $J \parallel B$  are discussed in terms of a simple model of resonant tunnelling. (Author abstract) 12 refs.

## Ultrasonic Effects

**096004 EFFECT OF ULTRASOUND ON THE ABSORPTION AND EMISSION SPECTRA OF LIGHT IN SEMICONDUCTORS.** Interest in studying the effect of low-frequency ultrasound on the absorption and emission spectra of light in semiconductors results from the possible use of this effect for controlling the parameters of optoelectronic semiconductor devices. Ultrasound causes a change in the forbidden energy gap and the permittivity of a semiconductor; in turn, this must affect the absorption of light in the semiconductor as well as its emitter characteristics. 8 refs.

**096005 BIPOLAR GATE ARRAY THAT RUNS FAST ON LOW POWER.** The combination of a bipolar technology and a logic scheme called differential logic is spawning a new generation of Ferranti Electronics Ltd. high-density gate arrays that run at speeds competitive with the fastest bipolar VLSI circuit. The combination of collector-diffusion isolation and differential logic yields devices that achieve power dissipation ratings in the CMOS class. Capable of gate delays in the 1-ns range, clock frequencies up to 250 MHz, and system speeds as high as 100 MHz, the new FAB3 devices are able to achieve power dissipation ratings ranging between 55 and 750  $\mu\text{W}$ . In addition, this third-generation, 1.5- $\mu\text{m}$  version of Ferranti's decade old CDI process requires only six to eight masking steps, compared with the 12 to 15 steps required for competitive bipolar and CMOS VLSI processes.

**096008 LOW-POWER 128-MHZ VCO FOR MONOLITHIC PLL IC'S.** The phase-locked loop (PLL) is implemented by 2- $\mu\text{m}$  bipolar-CMOS (BiCMOS) technology. The power dissipation of the PLL and the voltage-controlled oscillator (VCO) are 100 mW at 64 MHz and 25 mW for 1-128 MHz clock frequencies, respectively. The linearity of the VCO is  $\pm 0.5\%$  and the temperature stability is  $\pm 50$  ppm/ $^{\circ}\text{C}$ . The center frequency of the VCO is accurately set by using one fixed external resistor. The VCO has an advantage of noise insensitivity. To achieve these features, the VCO design uses an emitter-coupled multivibrator with a built-in timing capacitor and a controlled oscillation loop gain. The PLL can be applied not only to timing recovery for data transmission, but also to frequency synthesis and self-clocking for data recording. 9 refs.

**096009 EFFECT OF THIN INTERFACIAL OXIDES ON THE ELECTRICAL CHARACTERISTICS OF SILICON BIPOLAR DEVICES.** The effect of thin interfacial oxides on the impurity diffusion from polysilicon to the silicon substrate has been studied in detail. Polysilicon films were deposited on the silicon substrate under two different process conditions to control the thickness of interfacial oxides. Results show that the presence of about 1-nm-thick oxides retarded the impurity diffusion by about 10 nm. An increase of the sheet resistance of about 10% has been observed. Bipolar devices, which are sensitive to the impurity profiles, were fabricated with identical processing, apart from the polysilicon deposition conditions. A detailed analysis of their electrical characteristics shows the difference of collector current components and hence the increase of current gain by about two times. These results indicate that the effect of interfacial oxides on the impurity profile

is expressed by the segregation coefficient  $m$ , which is the ratio of  $C_{\text{Si}}/C_{\text{PolySi}}$  at the interface. The sensitivity of  $m$  for the device characteristics was calculated by a process-device simulator, and it is demonstrated that the current gain is a strong function of  $m$  for shallow emitters. 17 refs.

**096010 1.3- $\mu\text{m}$  CMOS/BIPOLAR STANDARD CELL LIBRARY FOR VLSI COMPUTERS.** The CMOS/bipolar standard cell library has been enhanced from 2 to 1.3  $\mu\text{m}$  for application to VLSI computers, such as 32-bit supermini- and microcomputers. This library has macrosells such as a 256-kb/8.4-ns ROM, 32-bit/4.5-ns carry propagation circuits for a 32-bit ALU, 4-kbyte/17-ns cache memory including an address translation function, and a 64-bit/37-ns multiplier. High integration density is obtained by using CMOS-based circuits and fast operation is achieved by using CMOS/bipolar sense circuits and drivers. In the cache memory, a functional sense amplifier, in which a conventional sense amplifier and a comparator are merged, is used. How to combine CMOS and bipolar devices in the macrosells along with application of the library to the VLSI computers is discussed. 23 refs.

**096011 GaAs/AlGaAs HETEROJUNCTION EMITTER-DOWN BIPOLAR CIRCUITS FABRICATED ON GaAs-ON-Si SUBSTRATES.** Small-scale GaAs HBT (heterojunction bipolar transistor) integrated circuits on silicon substrate are reported to demonstrate the potential of GaAs bipolar circuits fabricated on low-cost and large-diameter Si wafers. These circuits are 15-stage ring-oscillators and 256-b read-only-memories (ROMs). A maximum current gain of 25 was measured at a collector current density of 6250 A/ $\text{cm}^2$ . The ring oscillator consists of 15 inverters in series, and one output buffer. Each inverter is one transistor with four Schottky collectors for fan-out of four. This loaded ring oscillator showed a minimum gate-delay time of 200 ps at 10-mW/gate power dissipation. The delay increases to 400 ps at 4 mW/gate. Functional 256-b ROM circuits have also been obtained. The ROM uses emitter-down HBTs and double-level metals for interconnection. It is mask programmable and fully decoded. This circuit consists of approximately 120 gates. 2 refs.

**096012 EFFICIENT ALGORITHM FOR PHYSICAL-TOPOLOGICAL MODELING OF BIPOLAR SEMICONDUCTOR DEVICES WITH ALLOWANCE FOR THE NONLINEAR EFFECTS OF HEAVY DOPING AND HIGH INJECTION LEVEL.** General expressions are proposed for the electron and hole currents; they describe charge-carrier transport in an indirect-band semiconductor for an arbitrary doping level and any injection level. An efficient algorithm is described for physical-topological modeling of bipolar devices with allowance for recombination through deep levels, Auger recombination, electron-pole scattering, narrowing of the band gap, and other effects of heavy doping. The contribution made by nonlinear physical effects to the electrical characteristics of the structure is established. It is shown that electron-hole scattering, which is extremely important in calculation of the static volt-ampere characteristic, need not be taken into account in calculations for the process of reverse recovery in a diode. (Author abstract) 19 refs.

**096014 MEASUREMENT TECHNIQUE TO OBTAIN THE RECOMBINATION LIFETIME PROFILE IN EPI LAYERS AT ANY INJECTION LEVEL.** The modulation measurement technique proposed by the authors (1985) to obtain a high injection recombination lifetime profile is extended to any injection level in order to obtain both the majority-carrier and minority-carrier lifetimes as well as its profile along the epi layer. The technique is simulated by numerically solving the relevant equations and the extraction of a varying lifetime profile is demonstrated both at low and high injection levels. Some experimental results on n-n<sup>+</sup> epi layers of different doping and thicknesses are reported that demonstrate the possibilities of this measurement technique. Both minority-carrier and majority-carrier lifetimes are obtained from the measurements of lifetime as a function of the injection level. 13 refs.

#### Production

**096016 BICMOS HITS VOLUME PRODUCTION AT SARATOGA.** A new family of bipolar complementary MOS (BiCMOS) devices is introduced that uses a second generation 1.5 μm process, called Sabic III. The family is characterized by 64-Kbit, TTL-compatible SRAMs with speeds ranging from 25 to 35 ns and chip power consumption of only 500 mW active and 150 mW standby.

**Radiation Effects** See Also DATA STORAGE, SEMICONDUCTOR—Radiation Effects.

**096017 LASER SIMULATION OF SINGLE EVENT UPSETS.** A pulsed picosecond laser was used to produce upsets in both a commercial bipolar logic circuit and a specially designed CMOS static RAM test structure. A comparison of the laser energy necessary for producing upsets in transistors that have different upset sensitivities with the single-event upset (SEU) level predicted from circuit analysis showed that a picosecond laser could measure circuit sensitivity to SEUs. The technique makes it possible not only to test circuits rapidly for upset sensitivity but also, because the beam can be focused down to a small spot size, to identify sensitive transistors. 7 refs.

Buchner, S.P. (Martin Marietta Lab, Baltimore, MD, USA); Wilson, D.; Kang, K.; Gill, D.; Mazer, J.A.; Raburn, W.D.; Campbell, A.B.; Knudson, A.R. *IEEE Trans Nucl Sci* v NS-34 n 6 Dec 1987, 1987 Annu Conf on Nucl and Space Radiat Eff, Snowmass Village, CO, USA, Jul 28-31 1987 p 1228-1233.

**096018 INTRINSIC SEU RADIATION FROM USE OF HETEROJUNCTIONS IN GALLIUM ARSENIDE BIPOLAR CIRCUITS.** Use of GaAs/AlGaAs heterojunctions at the base-emitter junction in molecular-beam epitaxy (MBE)-type GaAs bipolar circuits reduces the thickness of the SEU (single-event upset)-sensitive volume associated with each transistor to about 0.2 μm. This results in a sharply reduced charge collection and a correspondingly sharp reduction in SEU sensitivity, even for low values of the critical charge. The effect is illustrated with an H<sup>12</sup>L (heterojunction inverted transistor integrated logic) gate array in which shift registers do not exhibit upsets on exposure to heavy ions with LET (linear energy transfer) values of up to 20 MeV-cm<sup>2</sup>/mg(GaAs), which is equivalent to over 30 MeV-cm<sup>2</sup>/mg(Si). A low-current version of the same shift registers exhibits an upset cross section of only 3 × 10<sup>-13</sup> cm<sup>2</sup>/b at an LET of 20 MeV-cm<sup>2</sup>/mg and zero at 11 MeV-cm<sup>2</sup>/mg(GaAs). Neither of the devices could be upset by exposure to 63-MeV protons at a fluence of 1 × 10<sup>12</sup> p/cm<sup>2</sup>, in agreement with the predictions made using CUPID simulation code. 10 refs.

**096019 PREDICTION OF DOSE TO FAILURE VERSUS DOSE RATE FOR A RECESSED OXIDE DIGITAL BIPOLAR MICROCIRCUIT.** The author reports on measurements made of microcircuit performance at different, low dose rates over extended periods of time in an attempt to assess the suitability of using the microcircuit in the satellite-mission radiation environment. It was planned to use Fairchild 54F251 parts in a 2.3-rad(Si)/h satellite environment for a five-year mission, in which they would accumulate 100 krad(Si). An initial test at 10,000 rad(Si)/h resulted in values of the input current high, I<sub>IH</sub>, which greatly exceeded the specified limit of 20 μA after the first radiation exposure at a level of 10 krad(Si). Typically, input currents above 20 μA are considered failures. Subsequent tests at lower dose rates resulted in total doses to failure which were much greater than 10 krad(Si), and allowed a prediction of successful operation for the mission duration. The analysis used to predict performance at low mission dose rates is applicable to other part types that experience similar radiation-induced effects. 11 refs.

#### Theory

**096021 INFLUENCE OF RECOMBINATION CENTERS ON THE RELAXATION PROCESS OF A 2D PHOTOEXCITED HOT ELECTRON PLASMA.** The effect of recombination centers on the relaxation process of photo-excited 2D electron systems in polar semiconductors is studied theoretically. Our analysis takes into account the most important mechanisms of relaxation. We find that under certain conditions recombinations to centers can drastically modify the e-ph interaction via reduction of screening. Consequently, the time behavior of the energy exchange rate between the electronic system and the lattice can also be altered. Our results indicate that recombination to centers affects, in different ways, the time evolution of the carrier temperature and the rate of energy exchange rate. Qualitative agreement with some experimental data lends support to the model and allows us to make some predictions. (Author abstract) 28 refs.

#### Transport Properties

**096022 NUMERICAL ANALYSIS AND INTERPRETATION OF THE SMALL-SIGNAL MINORITY-CARRIER TRANSPORT IN BIPOLAR DEVICES.** A simple and efficient one-dimensional numerical technique is presented that determines the small-signal minority-carrier transport in the quasineutral regions of bipolar devices, such as diodes and transistors, under sinusoidal excitation. The technique is applied to study small-signal properties of p-n junction diodes and bipolar

transistors. Examples treated include the frequency dependence of transistor current gain, the diffusion capacitance of a quasineutral base or emitter, and base-layer carrier propagation delay. 27 refs.

## SEMICONDUCTOR DEVICES, CHARGE COUPLED

See Also ASTRONOMY—Imaging Techniques; COATINGS—Antireflection Coatings; ELECTRONIC CIRCUITS, DELAY TYPE—Applications; IMAGE SENSORS; IMAGE SENSORS—Noise, Spurious Signal; IMAGE SENSORS—Performance; LOGIC CIRCUITS; NONDESTRUCTIVE EXAMINATION—Ultrasonic Applications; OSCILLOSCOPES, CATHODE RAY—Performance; PARTICLE DETECTORS; PHOTODETECTORS; PHOTODETECTORS—Control; SPECTROSCOPY, X-RAY—Equipment; TELEVISION EQUIPMENT—Cameras.

**096023 USE OF A CHARGE-COUPLED DEVICE FOR QUANTITATIVE OPTICAL MICROSCOPY OF BIOLOGICAL STRUCTURES.** The properties of a charge-coupled device (CCD) and its application to the high-resolution analysis of biological structures by optical microscopy are described. The CCD, with its high resolution, high sensitivity, wide dynamic range, photometric accuracy, and geometric stability, can provide data of such high quality that quantitative analysis on two- and three-dimensional microscopic images is possible. This description of the imaging properties of the microscope, and the high-quality image data provided by the CCD, allow sophisticated computational image processing methods to be used that greatly improve the effective resolution obtainable for biological structures. Image processing techniques revealed fine substructures in *Drosophila* embryonic diploid chromosomes in two and three dimensions. The same approach can be extended to structures as small as chromosomes. (Edited author abstract) 34 refs.

**096024 CCD AREA ARRAY DEVELOPMENTS.** There are a number of problems associated with CCD technology, and there is an emphasis on the development of device enhancements, especially in the field of 'area arrays' i.e. CCD sensing devices in which the pixels are grouped in a two-dimensional format. The article reviews CCD area array developments resulting in noise reduction, image uniformity, and elimination of a 'blooming' phenomenon.

Hickleton, Andrew. *New Electron* v 20 n 13 Jun 23 1987 p 16, 18.

**096025 VARIABLE IMAGE FORMAT FROM A CCD: ARE YOU LOCKED INTO THE 4:3 IMAGE FORMAT OF TELEVISION-COMPATIBLE CCD ARRAYS?** Most two-dimensional CCD arrays available in the marketplace today are configured in a 4:3 format to be compatible with television standards. Others are not. One of the others is the Texas Instruments TC211 device, which has 165 rows of pixels with 192 pixels per row and can be gated to use only certain portions of the chip as an active image area. The latter capacity is the result of a dump drain designed into the chip. This enables the user to clear unwanted charges from the CCD array quickly.

Profaizer, Rudy (Texas Instruments, Dallas, TX, USA). *Lasers Optonics* v 6 n 11 Nov 1987 p 86-87.

**096026 COMPENSATION FOR GAIN NONUNIFORMITY AND NONLINEARITY IN HgCdTe INFRARED CHARGE-COUPLED-DEVICE FOCAL PLANES.** Infrared CCD arrays generally require a compensation for the effect of gain and offset variation among the individual detectors of the array. Linear compensation techniques do not suffice for focal planes that exhibit a large nonlinearity of response combined with order-of-magnitude variations in threshold and saturation flux levels. This situation is common among hybrid architecture CCDs, particularly when HgCdTe is

the detector material. This paper reports on a multipoint piecewise-linear correction scheme employed on a HgCdTe infrared CCD focal plane. This technique allows a compensated response to be obtained in a computationally efficient manner. An experimental relationship between the number of calibration points and the amount of residual fixed-pattern noise is presented and compared to previous analytical models. (Author abstract) 3 refs.

**096027 ULTIMATE SENSITIVITY AND RESOLUTION OF PHOSPHOR/FIBER/CHARGE-COUPLED-DEVICE SYSTEMS.** Charge-coupled-device imagers have great potential to replace photographic film for recording cathode ray tube (CRT) displays. The basic problem, detection of electrons impacting with variable densities on a sensing screen, implies high sensitivity for single-electron detection. Few data have been published on CCD performance in this regime, especially as one component of a complete readout system. We report on the basic sensitivity and resolution of one possible system, the electron beam and phosphor coupled with fiber optics to a thermoelectrically cooled CCD camera. Observed performance indicates that present sensitivity is several CRT beam electrons per pixel and that resolutions of 25  $\mu\text{m}$  trace width present no problem. Improved experiments are expected to yield single-electron detection capability in the near future. The outlook for broad use of this readout in oscilloscopes, streak tubes, and imagers is discussed with regard to this performance. (Author abstract) 8 refs.

**096029 FREQUENCY FILTERING OF A SIGNAL BY INPUT CHARGE-COUPLED DEVICE UNITS.** It is shown that the frequency properties of input units employing charge-coupled devices (CCD) make it possible to impose the functions of frequency filtering on the input units, thereby simplifying the construction of a number of analogous units employing CCDs. It is shown for the example of two types of input units (with charge extrusion and with background current stabilization) that input units can accomplish a quasi-optimum passband filtering of signals. Mechanisms are examined for forming the lower and upper cutoff frequencies in these input units, their amplitude-frequency characteristics (AFC) are determined, and the influence of time quantization is examined. Experimental verifications of the proposed AFC model are presented. (Author abstract) 7 refs.

Vinetskiy, Yu.R. *Sov J Commun Technol Electron* v 32 n 5 May 1987 p 77-85.

**096030 CHARACTERISTICS OF OPTICAL CCD AS AN X-RAY IMAGE SENSOR.** We report here on the characteristics of a CCD for optical use in the several keV region. The CCD we used was an interline-transfer type device. We took X-ray images at energies of about 8 and 1.5 keV for various objects. We found that this device could yield sufficient information for a two-dimensional image. The spatial resolution is up to the individual pixel size ( $23 \times 27 \mu\text{m}$ ). The efficiency for X-rays is much superior to that of film. We measured the pulse-height distribution of X-rays in a photon-counting mode. We obtained a linear relation between the incident photon energy and the pulse height, while the energy resolution was kept constant. The effective depth of the depletion

layer of this device was calculated as being about 3  $\mu\text{m}$  from these measurements. We discuss the problems which must be faced in fabricating the CCD for X-ray use. (Author abstract) 8 refs.

**096032 FIRST TESTS WITH FULLY DEPLETED PN-CCD'S.** The authors have fabricated 280- $\mu\text{m}$ -thick fully depletable p-n charge-coupled devices (CCDs) on high-resistivity silicon (2.5 k $\Omega\text{-cm}$ ). Their operation is based on the semiconductor drift-chamber principle. They are designed as energy- and position-sensitive radiation detectors for (minimum) ionizing particles and X-ray imaging. Two-dimensional semiconductor device modeling demonstrates the basic charge-transfer mechanisms. Prototypes of the detectors have been tested in static and dynamic conditions. A preliminary charge-transfer inefficiency was determined to be  $6 \times 10^{-3}$ . The charge loss during the transfer is discussed, and an improved design, which is now being produced, is presented. 4 refs.

**096035 IMAGING AND NONDISPERSIVE SPECTROSCOPY OF SOFT X RAYS USING A LABORATORY X-RAY CHARGE-COUPLED-DEVICE SYSTEM.** This paper describes the design and performance of a laboratory instrument for imaging and nondispersive spectroscopy of soft x rays (300 eV to 10 keV) utilizing the Texas Instruments TI-4849 vital-phase CCD. This instrument has achieved a spatial resolution of 22  $\mu\text{m}$  (limited by pixel size) with an overall array area of 584  $\times$  390 pixels. It has achieved an energy resolution of approximately 140 eV FWHM for single-pixel  $^{55}\text{Fe}$  x-ray events (5.9 keV) with the CCD operated at  $-30^\circ\text{C}$ . We have operated the CCD in photon-counting mode at room temperature and have obtained x-ray spectra with an energy resolution of approximately 450 eV at 5.9 keV. The low energy x-ray sensitivity of the CCD also has been demonstrated by detecting carbon  $K_{\alpha}$  x rays (277 eV). (Author abstract) 6 refs.

**096036 ANALYSIS OF MTF OF CCD PUSH-BLOOM IMAGING SYSTEM IN ITS FLYING DIRECTION AND SELECTION OF THE OPTIMUM SUPERPOSED SAMPLING COEFFICIENT.** For a linear array CCD in a push-bloom imaging system, on condition that the input signal is a sine pattern with single frequency, the output signal spectrum is analyzed. The MTF expression of CCD in its flying direction is derived on certain conditions, which is then expressed as a product of  $\text{MTF}_1$ ,  $\text{MTF}_{\text{si}}$ ,  $\text{TF}_{\text{so}}$ . The effects of push-bloom coefficient  $\eta$  and superposed sampling coefficient  $\xi$  on MTF curves are analyzed. In general the value of  $\xi$  could be chosen as 2, at most as 4. **096037 CHOOSING CCDs FOR MACHINE VISION APPLICATIONS.** When using a charge-coupled device (CCD) camera, many critical camera parameters must be understood and matched to the requirements of the particular machine vision or robotic application. The final choice of a sensor depends on requirements in optics, sensitivity, resolution and dynamic range, as well as cost. In addition, the question of standard versus non-standard video formats must be addressed. The author reviews the three major solidstate imaging technologies: frame transfer (FT), x,y-addressed metal-oxide semiconductor (XY-MOS) and interline transfer (IL). Each has its advantages and disadvantages. 7 refs.

## Cooling

**096038 GENERALIZED APPROACH TO COOLING CHARGE-COUPLED DEVICES USING THERMOELECTRIC COOLERS.** This paper is concerned with the use of thermoelectric coolers (TECs) to cool charge-coupled devices (CCDs). Heat inputs to the CCD from the warmer environment are identified, and generalized graphs are used to approximate the major heat inputs. A method of choosing and estimating the power consumption of the TEC is discussed. This method includes the use of TEC performance information supplied by the manufacturer and equations derived from this information. Parameters of the equations are tabulated to enable the reader to use the TEC performance equations for choosing and estimating the power needed for specific TEC applications. (Author abstract) 2 refs.

**Design** See Also ELECTRON TUBES, TELEVISION CAMERA.

**096039 DESIGN OF LOW NOISE, HIGH PERFORMANCE X-RAY CHARGE-COUPLED-DEVICE CAMERAS.** In general, attention to a multitude of details is essential when designing low noise CCD cameras. This paper describes some of the critical details of the MIT x-ray CCD camera design. Special attention is given to those portions of the system that deviate from conventional practice in the design of CCD cameras. Furthermore, an attempt has been made to generalize the design so that both optical and x-ray requirements can be satisfied whenever possible. Currently, noise levels of  $< 8 \text{ e}^-/\text{rms}$  are routinely achieved with this design, and even lower levels ( $< 5 \text{ e}^-$ ) should be realizable. (Author abstract) 10 refs.

**096040 OPTIMIZING CHARGE-COUPLED-DEVICE DETECTOR OPERATION FOR OPTICAL ASTRONOMY.** We have operated two types of CCD detectors over the past several years: the three-phase thinned Texas Instruments 800  $\times$  800 and the thinned RCA 320  $\times$  512. Both detectors are operated in a slow-scan, cooled camera behind a variety of optical instruments at ground-based observatories, often involving low light levels. Emphasis is placed on optimizing the camera's operation with respect to quantum efficiency, readout noise, charge-transfer efficiency, dark current, full-well saturation, bias image flatness, residual image, and on-chip binning. Techniques for optimizing these properties are discussed. Our camera system is described, and information about the performance of our five operational CCDs is given. (Author abstract) 9 refs.

Leach, Robert W. (Univ of Arizona, Tucson, AZ, USA). *Opt Eng* v 26 n 10 Oct 1987 p 1061-1066.

**096041 FAST MEGAPIXEL CHARGE-COUPLED-DEVICE IMAGE ACQUISITION AND ANALYSIS SYSTEM FOR HIGH ENERGY NUCLEAR PHYSICS.** A two-camera system has been developed for photographing and analyzing images consisting of particle tracks from high energy collisions in a streamer chamber track detector. The charge-coupled-device (CCD) cameras view the collision region, with typical images consisting of more than 100 tracks. Each camera consists of a 1024  $\times$  1024 pixel CCD array. Up to three cameras can be read out simultaneously, at a rate of  $5 \times 10^5$  pixels/s/camera digitized to 9 bits, through a custom-designed multiplexing interface into an integer array processor, computer, and color display station. A software system has been developed that allows multiple asynchronous computer processes to record, analyze, and display the streamer chamber images. The system has been used in a high energy nuclear physics experiment for on-line analysis, digital data acquisition, and storage of streamer chamber events, with subsequent off-line image and physics analyses. (Author abstract) 7 refs.

**096042 64X64 PIXEL TWO-LAYER STRUCTURE INS-IRCCD.** A 64 $\times$ 64 pixel InSb-IRCCD two-layer structure has been developed. It is constructed with a back-illuminated InSb  $p^+n$  photodiode array and a buried Si-CCD  $p$ -channel. The photodiode array was manufactured using ion-implantation and anodic oxide/sputtered  $\text{Al}_2\text{O}_3$  double layer passivation processes, by which  $R_0A$  values of more than  $1 \times 10^5 \Omega\text{cm}^2$  were obtained. The photodiode array, polished to 20  $\mu\text{m}$  thickness, and the CCD are interconnected by a special In-bump technique involving electroplating and reforming to conical shapes, which assures complete electrical connections. Signal charges in the CCD storage gate containing the background ingredient are partitioned to two parts or skimmed. By these techniques, CCD gate capacities are minimized. The output signals are corrected

to form the IR image. Good system linearities, where  $\gamma = 1.00 \pm 0.01$ , and excellent responses,  $D_{\lambda\text{peak}} = 6.0 \times 10^{11} \text{ cm Hz}^{1/2} \text{ W}^{-1}$  and  $\text{NETD} = 0.05\text{-}0.06 \text{ deg}$ , have been obtained. (Edited author abstract). 9 Refs. In Japanese.

## Heterojunctions

**096043 DARK CURRENT IN SELECTIVELY DOPED N-ALGaAs/GaAs CCDs.** The dark current of Schottky-barrier-gate charge-coupled devices (CCDs) utilizing selectively doped N-ALGaAs/GaAs structures grown by molecular beam epitaxy was investigated. The generation rate of carriers in the CCD channel, i.e. the dark current, and its temperature dependence were measured in detail. The dark current was dominated by the reverse current of the Schottky barrier gate and consisted of the reverse current of the operating gate as well as that of the neighboring two gates. The reverse current was shown to be dominated either by the thermionic-field emission current or by the field emission current because of the high doping of ALGaAs. A measure of the reduction of the reverse current is also presented. (Author abstract) 12 refs.

## Imaging Techniques

**096044 FLASH TECHNOLOGY FOR CHARGE-COUPLED-DEVICE IMAGING IN THE ULTRAVIOLET.** The introduction of the flash gate has made possible the fabrication of backside-illuminated CCDs with high sensitivity and stability throughout a wide range of ultraviolet and visible wavelengths (100 to 5000 Å). It had been determined previously that the characteristics of the oxide layer beneath the gate are critical to the ultimate achievable CCD performance. However, by creating an improved oxide layer in conjunction with the flash gate, we are now able to produce CCDs with near-ideal uv performance. We present recent results and related background theory that optimize the flash gate specifically for application in the uv. (Edited author abstract) 15 refs.

Janesick, James R. (JPL, Pasadena, CA, USA); Campbell, Dave; Elliott, Tom; Daud, Taher. *Opt Eng* v 26 n 9 Sep 1987 p 852-863.

**096045 ULTRAVIOLET AND EXTREME ULTRAVIOLET RESPONSE OF CHARGE-COUPLED-DEVICE DETECTORS.** We present results of a program to enhance the ultraviolet and extreme ultraviolet response of charge-coupled devices. The ultimate goal of our program is to develop a large format device with both high and stable quantum efficiency from 100 to 3000 Å that can be used as a windowless imaging detector in a space environment. Ultraviolet quantum efficiency measurements have been made for several ion-implanted and laser-annealed test CCDs specially fabricated for this program. Quantum efficiencies as high as 22% at 2500 Å, where the absorption depth in silicon is approx. 55 Å, have been observed in one such test CCD. Quantum efficiency measurements of standard back-illuminated RCA and Tektronix CCDs are presented. (Edited author abstract) 18 refs.

Stern, R.A. (Lockheed Palo Alto Research Lab, Palo Alto, CA, USA); Catura, R.C.; Kimble, R.; Davidsen, A.F.; Winzenread, M.; Blouke, M.M.; Hayes, R.; Walton, D.M.; Culhane, J.L. *Opt Eng* v 26 n 9 Sep 1987 p 875-883.

**096046 LOW LIGHT LEVEL IMAGING WITH COMMERCIAL CHARGE-COUPLED DEVICES.** Low light level imaging with commercially available CCDs has been limited by CCD availability as well as by poor performance at low signal levels by many devices constructed for consumer applications. These performance limitations usually take the form of poor charge-transfer efficiency at the low temperatures and/or high noise levels associated with charge-detection schemes that normally need to operate only near room temperature. This paper describes a commercial virtual-phase CCD and associated operating mode that allow high performance low light level imaging at low temperatures. This capability makes the device ideally suited to both scientific and military low light level imaging applications. (Edited author abstract) 7 refs.

**096047 420×420 CHARGE-COUPLED-DEVICE IMAGER AND FOUR-CHIP HYBRID FOCAL PLANE.** We have designed and fabricated a 420×420 pixel front-illuminated CCD imager. The device was designed to be used both individually and as part of a four-chip focal plane consisting of four chips closely abutted in a 2×2 array, for a total resolution of 840×840 pixels. Attention has been paid to achieving low noise operation, and noise levels of less than 20 e<sup>-</sup> at a 1.0 MHz data rate have been achieved. We describe special focal plane assembly techniques with which we have achieved 1 μm relative positional accuracy between the chips. (Edited author abstract) 14 refs.

Burke, Barry E. (MIT, Lexington, MA, USA); Mountain, Robert W.; Daniels, Peter J.; Harrison, David C. *Opt Eng* v 26 n 9 Sep 1987 p 890-896.

**096048 LARGE AREA FOCAL PLANE COMPRISING CHARGE-COUPLED DEVICES AND FIBER OPTICS.** Driven by a requirement for an 80 mm square sensor, we have combined CCD and tapered fiber optic technologies to create a large area focal plane. Seven custom low noise CCD imagers are assembled onto four tapered fiber optic bundles to match the physical characteristics of a tube camera used in an operational system. Two taper ratios are used in the focal plane to meet requirements for broad search and high accuracy measurements in a single device. The entire focal plane is cooled to -40°C to reduce dark current to insignificance at an integration time of 0.6 s. The focal plane has been integrated into a camera head that has an all-digital interface. The camera preserves the low noise characteristics of the focal plane in a multichannel assembly. (Author abstract) 2 refs.

**096049 THOMSON-CSF FRAME-TRANSFER CHARGE-COUPLED-DEVICE IMAGERS: DESIGN AND EVALUATION AT VERY LOW FLUX LEVEL.** A slow-scan, cooled CCD camera system, similar to that used for astronomical observations, was constructed and used for testing CCD chips. Several devices were tested. This paper describes the design and performance of some Thomson-CSF solid-state area-array CCD sensors. These sensors use a frame-transfer organization adapted to operate in a double-interlaced-field readout mode with a memory zone (sensor TH 7861) or adapted to operate in a single-field mode without a memory zone (sensors TH 7882, TH 7883, TH 7884). We describe the system and the evaluation of the photometric performance of these chips, including quantum efficiency, readout noise, transfer efficiency, linearity, dark current, and field uniformity. Some projected developments of Thomson-CSF chips for scientific applications, such as the TH X31156 (1024×1024 pixels) and the buttable TH 7882 (TH X31157), are also presented. (Edited author abstract) 11 refs.

Beal, G. (Thomson-CSF, Boulogne-Billancourt, Fr); Boucharlat, G.; Chabbaï, J.; Dupin, J.P.; Fort, B.; Mellier, Y. *Opt Eng* v 26 n 9 Sep 1987 p 902-910.

**096050 OPTICAL TRACKING USING CHARGE-COUPLED DEVICES.** Techniques and instruments developed for extracting precise positional information from CCD images of point-source and extended optical targets are described. With the use of thinned, backside-illuminated devices, performance levels close to those expected from straightforward geometric considerations are obtained. For ideal point sources (i.e., stars outside of the earth's atmosphere), centerfinding accuracy of 1/100 pixel and measurement jitter of less than 1/250 pixel have been obtained. Tests showed that the main factor limiting tracker accuracy is small variation in the optical image shape rather than CCD noise or response nonuniformity. Methods of searching the entire field for the desired targets are described, along with windowing techniques for tracking. Also discussed are three examples of flight instruments previously developed or now being developed at the Jet Propulsion Laboratory. (Edited author abstract) 11 refs.

## Marketing

**096051 HIGH FRAME-RATE CCDs FIND A MID-MARKET NICHE.** In the last ten years, CCD imagers have gained widespread acceptance in two divergent markets - video cameras and specialized scientific applications. This article describes new applications for CCDs with performance positioned between these two segments.

Heidtmann, Denis; Smith, Paul; Yorsz, Jeff; Baran, Bruce. *Photonics Spectra* v 22 n 3 Mar 1988 p 127-128.

## Measurements

**096052 SIMPLE HIGH-FREQUENCY CHARACTERIZATION OF A THREE-PHASE CCD BY CONTROLLED FREE-CHARGE TRANSFER.** In this communication a technique is suggested where it is possible to characterize the charge-transfer inefficiency (ε) of a 3-phase CCD at high frequencies (1) without having to change the clock frequency and (2) with the clocks input and output circuitry operating at low frequency. This was achieved by the use of a simple virtual 2-phase clocking [2] of the CCD. Charge transfer under virtual 2-phase clocking of a 3-phase P-channel CCD is considered for demonstrating the effectiveness of the approach. 5 refs.

## Microscopic Examination

**096053 RESEARCH ON APPLICATION OF DOUBLE GETTERING TECHNIQUE ON CCD AND ITS INCREASED GETTERING EFFECT.** The application of double gettering in the fabrication of CCD is introduced and its general applicability has been proved. Based on the observation on the etched defect patterns and the study of the microimage by electron microscopy, it has been shown that the gettering effect of the phosphorus is greater than that of the defects. This result has also been proved by estimation using the ion pair model. It is argued that the double gettering process is a technique which can greatly increase the gettering effect. (Edited author abstract) 16 refs. In Chinese.

## Multiplexing

**096054 64×64-ELEMENT HgCdTe IRCCD FOR 3-5 μm BAND.** A 64×64-element HgCdTe IRCCD for 3-5 μm band has been successfully fabricated. Improvements in dynamic range and nonuniformity compensation are required to utilize maximum performance of a two-dimen-

sional IRCCD which consists of a HgCdTe photovoltaic array and a SiCCD multiplexer. The CCD multiplexer uses a new chip organization with an interlaced readout scheme and a storage/transfer common electrode configuration. Using these techniques, the IRCCD has 2.6 times greater dynamic range than conventional IRCCD, and 54 dB dynamic range is obtained for all 64×64 elements with 8% offset variation against 300 K background radiation. Mean detectivity  $D^*_{\lambda}$  is  $1.8 \times 10^{11}$  cmHz<sup>1/2</sup>W<sup>-1</sup> at peak wavelength of 4.7 μm. The nonuniformity compensation circuit which uses a digital signal processor (DSP) can execute both DC offset and responsivity compensation in real time. (Author abstract) 6 refs. In Japanese.

## Noise, Spurious Signal

**096055 CHARGE PARTITION NOISE IN CHARGE-COUPLED DEVICES.** In this paper we describe and analyze the internal noise sources of a signal charge partitioning circuit and indicate techniques for minimizing the internal noise of the circuit. Two noise sources are identified and described as a function of the circuit architecture and operating speeds: noise due to the trapping of thermal charge-density fluctuations (Johnson noise) and noise due to electrons scattered by the action of the partitioning gate. The noise due to the trapping of thermal charge-density fluctuations is dependent on the time it takes to divide the charge; at most, it is equal to the thermal Johnson noise of the integration well times the partition ratio. Noise due to the closing of the partitioning gate is dependent on the division ratio, the length of the spectrum gate, and its closure speed; it is, however, independent of the size of the charge packet being divided. With small division ratios (<10) and optimal operating speeds, the partition noise can be limited to fewer than 100 e<sup>-</sup>. (Author abstract) 6 refs.

## Performance See Also CAMERAS—Space Applications.

**096056 DUAL-CHANNEL CHARGE-COUPLED DEVICE FOR HIGH SPEED SIGNAL ACQUISITION.** The paper describes the design and development of a CCD shift register that can take analog samples of an electrical signal at rates up to  $1 \times 10^8$  samples/s and provide temporary storage for 1024 samples. It is intended for operation in a fast-in, slow-out mode for capturing high speed electrical transients. The requirements of fast clocking and moderate clock driver power led to the choice of a serial-parallel-differential channels. Differential operation provides good linearity. The two channels can be used independently or multiplexed for sampling at the highest rate. The CCD is of the buried-channel type and uses four-process, with two polysilicon layers to provide an overlapping transfer together with its behavior in an instrument. (Edited author abstract)

**096057 HIGH PERFORMANCE VISIBLE AND NEAR-INFRARED CHARGE-COUPLED-DEVICE ARRAY FOR SPECTROSCOPY APPLICATIONS.** This paper describes the design and performance of a scientific CCD array for use in NASA's Shuttle Image Spectrometer Experiment. The device is a four-phase, buried-channel CCD structure that operates in the frame-transfer mode. The sensor consists of 64×404 pixels (each 52 μm×52 μm), has a 100% fill factor, and operates in the visible and near-infrared spectral regions. In operation, the 404 horizontal elements provide spatial information, while the 64 vertical elements gives spectral

information covering the wavelength range of 400 to 1000 nm in 10 nm increments. The high full-well capacity of each pixel ( $> 2 \times 10^6$  electrons) and low noise floor ( $< 30$  electrons rms) yield a dynamic range of more than 95 db. The device has been designed to have good linearity characteristics. The unique dual-output structure allows a horizontal row to be read out to the right or to the left, or it can be split from the middle to both right and left output circuits simultaneously for high speed applications. The power dissipation of the device is about 60 mw. (Edited author abstract) 11 refs.

**096058 CURRENT STATUS OF THE 800×800 CHARGE-COUPLED-DEVICE IMAGE SENSOR.** This paper presents an updated version of an earlier paper describing the Texas Instruments three-phase 800×800 charge-coupled-device image sensor [800×800 charge-coupled device image sensor', *Opt. Eng.* 22(5), 607-614(1983)]. Although this device was originally designed to be used as the sensor for the Wide Field/Planetary Camera on the Hubble Space Telescope, it is now being used as the detector of choice on many ground-based telescope. We review the performance of the device and indicate the contributions it has made to the understanding of general CCD performance. (Edited author abstract) 32 refs.

**096059 CHARGE-COUPLED COMPUTING FOR FOCAL PLANE IMAGE PREPROCESSING.** A new class of charge-coupled devices called charge-coupled-computing devices is described. These analog circuits perform arithmetic functions such as addition, subtraction, and magnitude comparison in the charge domain. The circuits are compact and are designed to be insensitive to rail voltages, simplifying their utilization. These devices, in conjunction with input, output, and analog memory circuits, can be combined to form a simple but general-purpose and fully programmable charge-coupled computer. A prototype charge-coupled computer has been fabricated and tested. Prospects for forming a large array of computers (e.g., 1000 to 10,000) on a single chip for spatially parallel image preprocessing are discussed. Such image plane preprocessing of data would find use in real-time mobile robot vision systems, in which low power, lightweight computing is critical for economical viability. (Author abstract) 8 refs.

**096060 CHARGE-COUPLED-DEVICE CHARGE-COLLECTION EFFICIENCY AND THE PHOTON-TRANSFER TECHNIQUE.** The charge-coupled device has shown unprecedented performance as a photon detector in the areas of spectral response, charge transfer, and readout noise. Recent experience indicates, however, that the full potential for the CCD's charge-collection efficiency (CCE) lies well beyond that realized in currently available devices. In this paper we present a definition of CCE performance and introduce a standard test tool (the photon-transfer technique) for measuring and optimizing this important CCD parameter. We compare CCE characteristics for different types of CCDs, discuss the primary limitations in achieving high CCE performance, and outline the prospects for future improvement. (Author abstract) 7 refs.

## Radiation Damage

**096061 EXTREME DAMAGE EVENTS PRODUCED BY SINGLE PARTICLES.** Recent measure-

ments of permanent displacement damage produced in charge-coupled devices by single neutron and proton interactions revealed that some of the events exceeded the mean value by more than a factor of ten. These extreme events cannot be readily explained in terms of calculated recoil spectra. In view of this finding, the authors estimate the probability of exceeding a given level of damage as the particle fluence is increased and multiple events occur. Analytical methods applicable to this problem are described and applied to the reported displacement damage data. The results indicate that the character of the damage distributions will change rapidly as the particle fluence is increased and a transition is made from single to multiple events. Although the damage distribution approaches a Gaussian form, the extreme events will persist up to exposure levels 100 times higher than that used in the reported experiments.

## Space Applications

**096062 STAR MAPPER USING A LINEAR CHARGE-COUPLED-DEVICE ARRAY.** A star mapper using a Fairchild 2048-element linear CCD array (CCD 143) has been developed for the Indian Remote Sensing Satellite (IRS-1A), which is scheduled for launch in 1987. The star mapper is designed to scan stars up to 5th magnitude by using the orbital motion of the sun synchronous satellite, with a swath of 8° across the scan direction. Design details of the star mapper along with some test results of the qualification model are presented. (Author abstract) 2 refs.

### Applications

**096064 CHARGE TRANSFER DEVICE DETECTORS FOR ANALYTICAL OPTICAL SPECTROSCOPY - OPERATION AND CHARACTERISTICS.** In this paper, charge transfer devices (CTDs) are described. Detector characteristics pertinent to spectroscopic application - including quantum efficiency, read noise, dark count rate, and available formats - are emphasized. Unique capabilities, such as the ability to nondestructively read out the detector array and the ability to alter the effective detector element size by a process called binning, are described. CTDs with peak quantum efficiencies over 80% and significant responsivity over the wavelength range of 0.1 nm to 1100 nm are discussed. (Edited author abstract) 24 refs.

**096065 SPECTROCHEMICAL MEASUREMENTS WITH MULTICHANNEL INTEGRATING DETECTORS.** This article covers three major topics related to the optimum use of integrating detectors in analytical

spectroscopy. The advantages of employing integrating multichannel detectors in analytical spectroscopy, rather than a single detector in a wavelength scanning system or an interferometer, are discussed. Included are detector read noise considerations. When one is employing an integrating detector in luminescence, absorption, and emission applications, achievable sensitivity is dependent on differing detector parameters. (Edited author abstract) 23 refs.

## Contacts

**096066 INFLUENCE OF CATHODE CONTACTS ON NEAR-MICRON INP TRANSFERRED ELECTRON DEVICES.** We have performed an experimental investigation of twenty-five 1.5 to 2.0  $\mu$ m long InP TED's in tunable resonant structures at frequencies in the 75-100 GHz regime, and have simulated their behavior, and that of shorter devices. We have found that the cathode boundary condition determine the operation of near-micron InP TED's in following ways: it controls the threshold conditions; it controls the required dc bias power; it affects the transit-time frequency of the device; and it influences the electric field profile for an appreciable distance from the cathode. (Edited author abstract) 8 refs.

## Degradation

**096068 EFFECT OF IMPACT IONIZATION INDUCED BIPOLAR ACTION ON N-CHANNEL HOT-ELECTRON DEGRADATION.** The relationship between the total impact ionization rate and the measured substrate current is analyzed, using short-channel NMOS devices. It is shown that holes that are injected into the source and turn on the parasitic source-bulk-drain bipolar may actually be a significant portion of the total impact

ionization current. The authors explain how the commonly used model, which ignores this bipolar effect, can lead to incorrect predictions regarding hot-electron degradation. A related criterion for maximum source-drain voltage during accelerated stress is discussed and justified. 4 refs.

**096069 VELOCITY OVERSHOOT IN ULTRA-SHORT-GATE-LENGTH GaAs MESFET'S.** GaAs MESFETs with ultrashort gates between 0.035 and 0.065  $\mu\text{m}$  were fabricated to determine trends in their DC transconductance as a function of gate length. It is found that overshoot in the channel causes a considerable increase in the average electron velocity. An approximation based on the gradual channel approximation becomes valid at ultrashort gate lengths due to an increased percentage of the channel that is velocity-saturated. 20 refs.

**096070 RELIABLE METHOD FOR 0.25-MICRON GATE MESFET FABRICATION USING OPTICAL PHOTOLITHOGRAPHY.** GaAs MESFETs with  $\frac{1}{4}$  micron ( $\mu\text{m}$ ) gate lengths recently have become commercially available. We have avoided costly and slow direct-write e-beam by developing a reliable optical lithography process with which we reproducibly make 0.25  $\mu\text{m}$  gate length MESFETs. Fabrication involves a bilayer technique incorporating positive photoresist image reversal and subsequent creation of an Al lift-off mask. The critical process step involves the controlled erosion of a reverse polarity 0.65  $\mu\text{m}$  positive photoresist line to 0.25  $\mu\text{m}$ . The final line length is reproducible to within  $\pm 10\%$ . We fabricated  $0.25 \times 300$ , 200 and 150  $\mu\text{m}$  gate MESFETs. The typical wafer yield is 50% with a gate length uniformity of  $\pm 10\%$  across a 2 inches diameter wafer. Using this process, we obtained 12 dB gain @ 24 GHz for  $0.25 \times 150 \mu\text{m}$  FETs. 9 refs.

**096071 GAAS MESFET LASER-DRIVER IC FOR 1.7-GBIT/S LIGHTWAVE TRANSMITTER.** GaAs monolithic integrated circuits for modulating junction lasers (laser drivers) have been developed for a 1.7-Gb/s lightwave communication system. The modulation currents can be varied continuously from a few mA up to 50 or 100 mA, depending on the types of laser drivers. It has been demonstrated that devices of the low-current type are capable of driving a 50- $\Omega$  load with a 50-mA modulation current with pulse rise and fall times (10% to 90%) less than 200 ps, and the high-current devices are capable of driving a 25- $\Omega$  load with up to 100-mA modulation current with pulse rise and fall times less than 250 ps. Nearly temperature-independent performance has been achieved from 0°C to 70°C. The laser drivers are also capable of providing output DC currents proportional to the duty cycle of input data for the purpose of duty-cycle-independent feedback control of junction lasers. The circuit designs and performance of these devices are

described. 5 refs.

**096072 IMPROVED MODFET PERFORMANCE THROUGH ION IMPLANTATION IN THE GATE REGION.**  $\text{Al}_x\text{Ga}_{1-x}\text{As}/\text{GaAs}$  modulation-doped FETs (MODFETs) are reported which utilize low-dose p-type implantation under the gate region to improve the source-drain breakdown voltage. The gate-channel forward turn-on and reverse breakdown voltages are also improved due to this construction. Extremely low output conductances of less than 0.2 mS/mm were obtained with open-circuit voltage gains exceeding 250. Such improvements are important for achieving high RF power in microwave device applications, and have similarly significant implications for digital circuitry. The enhanced gate characteristics are thought to arise because the net donor concentration under the gate region is reduced due to the implanted p-type ions. The improved output conductance and drain breakdown may in part also be due to the fact that during annealing, the implanted ions diffuse laterally to the drain region. This results in a further reduction and grading of the net donor concentration in the region between the gate and the drain. 11 refs.

**096073 GALLIUM-ARSENIDE E- AND D-MESFET DEVICE NOISE CHARACTERISTICS OPERATED AT CRYOGENIC TEMPERATURES WITH ULTRALOW DRAIN CURRENT.** The low-frequency noise characteristics of GaAs MESFETs operating at very low power and at cryogenic temperatures of 77 and 10 K as well as at room temperature are discussed. A self-aligned gate and a buried p-layer were incorporated to maximize device gain and minimize low-frequency noise. Measurements at 77 K show a noise voltage spectral density of 1.0-2.0  $\mu\text{V}/\sqrt{\text{Hz}}$  at 1.0 Hz (referred to the transistor input) with a drain current of 1.0  $\mu\text{A}$ . 9 refs.

**096074 UNIFORMITY OF THRESHOLD VOLTAGE FOR MESFETs FABRICATED ON VGF GaAs SUBSTRATES.** Improved uniformity of threshold voltage is shown for MESFETs fabricated on GaAs substrates grown by a novel vertical gradient freeze technique when compared to devices fabricated on LEC GaAs substrates. The improved uniformity is most likely related to the decreased dislocation density and reduced impurity clustering in the VGF material. (Author abstract) 17 refs.

Reynolds, C.L. (AT&T, Reading, PA, USA); Gibson, W.C.; Clemans, J.E. *Electron Lett* v 23 n 23 Nov 5 1987 p 1222-1223.

**Mathematical Models** See Also TRANSISTORS, FIELD EFFECT—Electronic Properties; TRANSISTORS, FIELD EFFECT—Ion Implantation; TRANSISTORS, FIELD EFFECT—Noise.

**096075 TWO-DIMENSIONAL NUMERICAL MODELING OF HEMT USING AN ENERGY TRANSPORT MODEL.** A two-dimensional numerical computer simulation based on the analysis of the first three moments of the Boltzmann equation, known as the

energy-transport model, has been used to study various two-dimensional effects on the performance of  $\text{AlGaAs}/\text{GaAs}$  heterostructure field-effect transistor. The results are presented for half-micron gate length. The calculation reveals significant electron current contribution coming from the  $\text{AlGaAs}$  region between the source and gate, contributing to the reduction of access resistance. As the electrons acquire large energies near the drain side edge of the gate, real-space transfer to the  $\text{AlGaAs}$  region from the 'two-dimensional' electron gas channel occurs. However, at the drain end, the electron current is confined at the  $\text{GaAs}$  side of the heterointerface. The result shows insignificant current contribution from regions of depth greater than 0.048  $\mu\text{m}$  into the undoped  $\text{GaAs}$  bulk. (Edited author abstract) 14 refs.

Buot, F.A. (US Naval Research Lab, Washington, DC, USA). *COMPEL Int J Comput Math Electr Electron Eng* v 6 n 1 Mar 1987 p 45-52.

**096076 IMPROVED MODFET PERFORMANCE THROUGH GATE CURRENT CONTROL.** Using an improved physical theory of the gate current in MODFETs the authors were able to decrease the gate current in the devices. By using an  $\text{AlAs}$  spacer layer, the turn-on voltage of the devices (i.e., the voltage at which the gate current density reaches  $5 \mu\text{A}/\mu\text{m}^2$ ) was increased to 1.2 V. This improvement increased the noise margin in an inverter with a fanout of one to greater than 500 mV at room temperature, and greater than 300 mV at 170°C. The lower gate current allowed the extrinsic transconductance ( $G_m$ ) to peak at a higher gate voltage, which resulted in a higher peak  $G_m$ . The average  $G_m$  for a 1- $\mu\text{m}$  FET over a 3-in. wafer reached 286 mS/mm. Here, the model for the gate current in MODFET devices and data from MODFETs fabricated with  $\text{AlAs}$  spacer layers are presented.

**096078 LARGE-SIGNAL, ANALYTIC MODEL FOR THE GAAS MESFET.** An analytic, large-signal model for the GaAs MESFET is presented. The device model is physics-based and describes the conduction and displacement currents of the FET as a function of instantaneous terminal voltages and their time derivatives. The model allows arbitrary doping profiles in the channel and is thus suitable for the optimization of ion-implanted and buried-channel FETs. It also accounts for charge accumulation in the conducting channel at high electric fields and the associated capacitance in a self-consistent manner. Theoretical predictions of the model are correlated with experimental data on X-band power FETs and excellent agreement is obtained. 20 refs.

Khatibzadeh, M. Ali (North Carolina State Univ, Raleigh, NC, USA); Trew, Robert J. *IEEE Trans Microwave Theory Tech* v 36 n 2 Feb 1988 p 231-238.

**096079 MODELING OF BISTABLE DEVICE I-V CHARACTERISTIC RESULTING FROM CONDUCTIVITY MODULATION IN SEMICONDUCTORS.** The bistable I-V characteristic in a diode-like device structure that resembles the double-base diode is predicted by numerical solution. This bistable characteristic results from the conductivity modulation effect coupled with an ohmic voltage drop produced by the current through a shunt resistor. The back-surface field effect has a significant influence on the minority-carrier transport of this type of bistable I-V characteristic. A two-dimensional numerical simulation is performed to explore the steady-state bistable I-V characteristic including a negative dynamic conductance region. To better understand this mechanism, a DC equivalent circuit based on a one-dimensional current-flow model is proposed. The I-V characteristic obtained by this equivalent circuit agrees well with an exact two-dimensional numerical simulation result. 10 refs.

**096081 TWO-DIMENSIONAL SIMULATION OF SUBMICROMETER GAAs MESFET'S: SURFACE EFFECTS AND OPTIMIZATION OF RECESSED GATE STRUCTURES.** The surface potential effect in GaAs MESFETs causes a depleted zone to form not only between the source and gate, but also between the gate and drain. The consequences of this phenomenon on the device behavior, the DC and AC characteristics, and the expected performance are studied. For this purpose, a two-dimensional resolution of the basic semiconductor equations is used. This model takes into account relaxation effects by including an energy relaxation equation. The dependence of MESFET characteristics such as transconductance, output conductance, and capacitance on the dimensions of the zone where surface potential effects occur is given. Some interesting conclusions concerning the optimization of recessed-gate structures are drawn. 21 refs.

**Noise** See Also AMPLIFIERS—Theory.

**096083 MICROWAVE NOISE CHARACTERIZATION OF GAAS MESFET'S: EVALUATION BY ON-WAFER LOW-FREQUENCY OUTPUT NOISE CURRENT MEASUREMENT.** A simplified noise equivalent circuit is presented for submicrometer-gate-length MESFETs, in the common-source configuration, consisting of five linear circuit elements: the gate-to-source capacitance, the total input resistance, the transconductance, the output resistance, and a noise current source of spectral density at the output port. All of these elements can be determined by on-wafer measurements, and the noise current can be measured at a low frequency. The minimum noise figure of the device calculated from this model and bias and frequency dependence of the noise figure are shown to be in agreement with microwave noise figure measurements. This technique is then used for determination of the minimum noise figure of a device solely by on-wafer measurements rather than by microwave measurements. The proposed technique can be utilized rapidly, conveniently, without the need for tuning, and at the wafer stage of device fabrication. 21 refs.

**096084 GATE CURRENT 1/F NOISE IN GAAS MESFET'S.** Gate current 1/f has been investigated on commercial GaAs MESFETs. It is found that devices with slight differences in drain current noise can have quite a difference on type of  $I_g$  versus  $V_{ds}$  and  $V_{gs}$  and even greater differences in the gate current noise. The 1/f part in the spectrum of the gate current is a better diagnostic tool for characterizing the quality of the junction than the drain current noise. A model that is based on a Schottky barrier shunted by edge currents are proposed to explain the experimental results. 7 refs.

**096086 TRANSIENT RADIATION EFFECTS IN**

ALGAAS/GAAS MODFET'S. Transient radiation effects were measured in AlGaAs/GaAs MODFETs. The temperature dependence of the long-term transients was measured using 3-ns flash X-ray pulses, allowing the observation of trapping levels. These long-term transients were similar to those observed in conventional GaAs FETs, with the exception that persistent photoconductivity was observed in some devices. 16 refs.

**Simulation**

**096087 ERROR INDICATION AND ADAPTIVE REFINEMENT IN SEMICONDUCTOR DEVICE SIMULATION.** Two error indicators for an elliptic problem are presented. The first is based on the solution of a local Neumann problem, and the second is the error in the gradient field. For semiconductor device simulation a hybrid error indicator with three components is presented. The first component arises from the discretization of the Poisson equation by the finite element method, and the other two components are the  $L_2$  norm of the error in the current densities. Examples of the adaptive scheme are provided for a p-n diode, a MESFET and a MOSFET. (Author abstract). 23 Refs.

**Spectrum Analysis**

**096088 OBSERVATION OF LARGE ABSORPTION MODULATION IN A QUANTUM-WELL FIELD-EFFECT DEVICE.** Deep quenching of absorption ( $\Delta\alpha > 10^4 \text{ cm}^{-1}$ ) over a 90-meV spectral range brought about by field-induced carriers has been observed directly for the first time at room temperature in a special AlInAs/GaInAs/AlInAs single quantum-well (SQW) MODFET for a modest gate voltage change from -0.6 to 1.5 V. Optical measurements were carried out in the 1.0- $\mu\text{m}$ -to-1.7- $\mu\text{m}$  range using the focused output from a monochromator. Photocurrent spectrum taken at zero bias shows characteristic absorption steps due to 2-D subbands. To investigate the effect of gate bias on the absorption spectrum, the light was focused onto the optical test pad through the substrate, reflected off the Cr/Au electrode, and was detected by a PbS photodetector. The gate-voltage induced modulation in the reflected light was measured using a lock-in amplifier. The measured difference spectrum clearly shows a large change at the position of  $n_s = 1$  exciton peaks with a maximum  $\Delta I/I$  of approximately 2%. This amounts to  $\Delta\alpha$  approximately  $10^4 \text{ cm}^{-1}$ , which corresponds to total quenching of the excitonic absorption. The observed absorption change is primarily due to the filling of the generalized phase space by free carriers. It is strong enough for detecting the logic state in SQW devices. 4 refs.

**Thermal Effects**

**096089 ENHANCED TEMPERATURE DEPENDENCE OF MESFET CHARACTERISTICS BY BACKGATE AND SIDEGATE BIASING.** An enhanced temperature dependence of drain saturation current as well as threshold voltage is observed for ion-implanted GaAs MESFET's when backgate or sidegate bias voltage is applied. By performing conductance DLTS measurement based on backgating effect of FETs, three kind of traps, namely Cr, HL4 and HL8, are

identified for the substrate prepared by Horizontal Bridgman method. Also three kind of traps, namely EL2, HL4 and HL8, are identified for the non-doped Liquid Encapsulated Czochalski (LEC) substrate. Simulation of the stationary characteristics of FETs is made at various temperature using a device model which includes both the depletion region at the n-i (channel-substrate) junction and influence of the deep traps. ## Applications

**096090 SENSING BEHAVIOR OF Pd-SnO<sub>x</sub> MIS STRUCTURE USED FOR OXYGEN DETECTION.** A new type of oxygen sensor with a Pd-SnO<sub>x</sub>-Si<sub>3</sub>N<sub>4</sub>-SiO<sub>2</sub>-Si-Al MIS structure has been developed, and is capable of detecting partial pressures of less than 0.1 Torr of O<sub>2</sub> at 300 K. The detection principle of this device is based on the changes in ionic charge of the SnO<sub>x</sub> film during oxygen adsorption and consequent changes in the flat-band voltage. Device fabrication processing, SnO<sub>x</sub> film composition, structure and electrical characterization are described briefly. The experimental results for the steady-state and transient behavior of the device are presented. The concentration of oxygen ions adsorbed in the MIS structure at a given temperature and oxygen pressure are measured by the triangular voltage sweep method, which confirmed a postulated detection mechanism. (Author abstract) 10 refs.

## Electronic Properties

**096091 ELECTROLUMINESCENCE OF CdS/LANGMUIR-BLODZHE/Au STRUCTURES.** Electroluminescence is discovered in metal-dielectric-semiconductor structures based on CdS and Langmuir films of stearic acid. A tunnel-injection mechanism of its excitation is established. The specific resistance of the substrate material is about 10 Ω·cm. The ohmic contact to the CdS was created by burning in indium, while the contact to the Langmuir layer was formed by spraying on gold in a vacuum of at least 10<sup>-6</sup> mm Hg. (Edited author abstract) 2 refs.

**096092 IMPROVEMENT OF THE ELECTRICAL PROPERTIES OF THE AlN/GaAs MIS SYSTEM AND THEIR THERMAL STABILITY BY GaAs SURFACE STOICHIOMETRY CONTROL.** The GaAs surface pre-treatment conditions for the MOCVD-AlN/GaAs MIS diodes are investigated. An AsH<sub>3</sub> pre-treatment just prior to the AlN deposition degraded the C-V characteristics of AlN/n-GaAs MIS diodes in the accu-

mulation side. The characteristics and their stability were drastically improved by a pure H<sub>2</sub> pre-treatment at 500°C. It was confirmed that the free As at the interface generates surface states near the conduction band edge and that control of the surface stoichiometry and atomic structure is necessary to improve the MIS characteristics. (Author abstract) 9 refs.

**096093 CAPACITANCE-VOLTAGE CHARACTERISTICS OF Hg<sub>1-x</sub>Cd<sub>x</sub>Te MIS DEVICES.** The C-V characteristics of N- and P-type Hg<sub>1-x</sub>Cd<sub>x</sub>Te (x=0.2~0.56) MIS devices fabricated with double dielectric layers consisting of anodic oxide and ZnS are studied. The nonparabolicity and degeneracy of Hg<sub>1-x</sub>Cd<sub>x</sub>Te conduction band are taken into account in the theoretical treatment based on Kane model. In calculating high frequency capacitance, the redistribution of minority carriers in the inversion layer is also considered. The C-V measurements are carried out within the frequency range of 20Hz ~ 10MHz and the temperature range of 26~200K. For Hg<sub>0.7</sub>Cd<sub>0.3</sub>Te MIS device, the results at 80K show that the fixed positive charge density is 8~10×10<sup>11</sup>cm<sup>-2</sup>, slow interface trap density 4~10×10<sup>10</sup>cm<sup>-2</sup>, and minimum fast surface state density 1.72×10<sup>11</sup>cm<sup>-2</sup>eV<sup>-1</sup>. (Author abstract) 9 refs. In Chinese.

## Electronic Properties

**096094 HOT HOLE CREATION DUE TO IMPACT EXCITATION IN THE METAL ELECTRODE OF A FORWARD BIASED MIS STRUCTURE.** A theoretical investigation is made of the process by which hot electrons in a metal cause impact excitation of the electrons in the Fermi sea to create a hot hole population. Expressions for the energy and velocity distributions of the holes are obtained for a metal with a spherical Fermi surface, assuming Thomas-Fermi screening. A simple model is used to calculate the probability that an electron injected into the metal, from the insulator of a metal-insulator-semiconductor (MIS) diode, can create a hole capable of reaching the MI interface. The theory is applied to an electroluminescent Au/i-ZnS/n-ZnS MIS structure and the hole flux at the metal-insulator interface is calculated. The results show that the impact excitation model provides a plausible explanation of the behavior of the electroluminescent efficiency of such MIS diodes. (Author abstract) 24 refs.

## Mathematical Models

**096095 BULK LEVELS AND INTERFACE CALCULATIONS FOR NARROW BAND-GAP SEMICONDUCTORS.** Accurate small-signal low and high frequency capacitance-voltage characteristics of Metal-Insulator-Semiconductor (MIS) devices in narrow band-gap semiconductors are presented. The unique physical features of narrow band-gap semiconductors are incorporated simultaneously in the calculations: the nonparabolicity of the conduction band, degeneracy in the occupancy of the free carriers and compensated and partially ionized impurities or defects. Accurate high frequency characteristics are calculated by taking into account minority carriers redistribution which causes polarization of the inversion layer. The analysis presented describes MIS capacitance curves in terms of the detailed bulk band structure. This approach is important for defect

semiconductors such as HgCdTe. (Author abstract) 8 refs.

## Measurements

**096096 MEASUREMENT OF THE PARAMETERS OF MIS STRUCTURES WITH COMPENSATION OF THE EFFECT OF THE CAPACITANCE OF THE DIELECTRIC.** A scheme for measuring the parameters of an MIS structure excited by a low-amplitude impulsive signal is described. The measurements are performed under conditions of compensation of the capacitance of the dielectric. The scheme enables measurement of the capacitance of a semiconductor in the range 2-2000 pF with the capacitance of the dielectric varying from 5 to 500 pF and a surface state recharging time of the constant states varying from 30 to 300 μsec with a reduced error of ±3%. (Author abstract) 5 refs.

## Modeling

**096097 USING THE METHOD OF INTEGRAL DYNAMIC VOLT-AMPERE CHARACTERISTICS TO STUDY IONIC INSTABILITY IN MIS DEVICES.** The method of dynamic volt-ampere characteristics (DVAC) is one of the most popular for measuring electrical relaxation and ion drift in the insulating layers of MIS devices. With this method the basic current that arises when a linear voltage is applied to an MIS device is measured and the number of mobile ions in the insulator is found by integrating the measured current with respect to voltage. An improved method of recording a DVAC is examined here and consists of measuring the integral of current with respect to voltage directly (integral DVACs, or IDVACs). The IDVAC method is used to measure the number of mobile ions at elevated temperatures in SiO<sub>2</sub> and SiO<sub>2</sub>+fluorine-bearing layers on silicon and corrosion-resistant alloys with aluminum and polysilicon electrodes. 6 refs.

## Optical Properties

**096098 REFLECTOMETRY MEASUREMENT OF OPTICAL PARAMETERS OF Au/SiO<sub>2</sub>/Si FILMS.** A new insight into the analysis of multiple-angle reflectometry measurements has led to unambiguous measurements of the thickness and optical constants of thin films. These were deposited as the metal layer of metal/oxide/silicon structures. The method involves finding suitable wavelength(s) and angles for which variations in the calculated reflectivity ratio (R<sub>p</sub>/R<sub>s</sub>), caused by assuming different thicknesses, cannot be compensated for by assuming different optical constants. For each condition, the thickness is determined from measurements made at one wavelength. The gold thickness determinations are believed to be accurate to ±0.3 nm and the optical constants are consistent with those of other workers using simple gold-substrate systems. (Author abstract) 15 refs.

Performance See Also TRANSISTORS, FIELD EFFECT—Heterojunctions.

**096099 GaAs MIS STRUCTURES WITH SiO<sub>2</sub> USING A THIN SILICON INTERLAYER.** The introduction of a pseudomorphic Si interlayer, about 1.0 nm thick, is found to improve the MIS characteristics of the SiO<sub>2</sub>/GaAs system. Quasistatic and high-frequency capacitance/voltage data from such a novel capacitor structure on n-GaAs indicate that the surface of the GaAs is swept from inversion to accumulation. X-ray photoelectron

spectroscopy and ion scattering spectroscopy confirm the presence of the Si layer and its complete coverage of the GaAs surface. The Si layer minimizes the formation of any detrimental native oxides and thus controls the chemical nature of the GaAs surface. This approach has implications in the development of metal-insulator-semiconductor systems in general. (Edited author abstract.) 11 Refs.

## Physical Properties

**096100 ELECTROPHYSICAL PROPERTIES OF METAL-DIELECTRIC-SEMICONDUCTOR STRUCTURES OF CdS LANGMUIR-BLODZHE FILM/Au.** The electrophysical properties of metal-dielectric-semiconductor structures with an insulating multimolecular layer of stearic acid formed on CdS through the Langmuir-Blodzhe technology are investigated. The volt-ampere and volt-Faraday characteristics of the structures point to a tunnel-injection mechanism for current flow. (Author abstract) 4 refs.

Georgobiani, A.N.; Rambidi, N.G.; Todua, P.A.; Sheshtakova, E.F.; Eltazarov, B.T. *Sov Phys Lebedev Inst Rep* n 9 1987 p 55-59.

**Semiconductor Insulator Boundaries** See Also SEMICONDUCTING INDIUM COMPOUNDS—Heat Treatment.

**096101 InP NATIVE OXIDE: A DRIFT FACTOR IN InP-MIS.** It is shown that a native oxide in a InP-MIS structure is a key parameter in the time instability of the device. This is demonstrated in experiments on Al/SiO<sub>2</sub>/native oxide/InP structures with different native oxide thicknesses. A minimum of the flat-band voltage drift is observed for thicknesses close to 30 Å. A model which considers traps distributed as a continuum of states in the insulator and tunneling with the InP surface channel is consistent with these results. (Author abstract) 14 refs.

**096102 REDUCTION OF THE CONCENTRATION OF SLOW INSULATOR STATES IN SiO<sub>2</sub>/InP-MIS STRUCTURES.** In this paper we will discuss the influence of the deposition temperature, the spatial separation of sample and plasma ('indirect plasma method'), and the addition of phosphorus into the reaction chamber during the initial period of insulator deposition on the properties of n-type and p-type InP-MIS capacitors. Plasma-enhanced chemical vapor deposited silicon dioxide is used as insulator. The samples were characterized by means of capacitance/voltage (C(V)) and deep level transient spectroscopy (DLTS) measurements. Only minor hysteresis of the C(V) curves and concentrations of slow insulator states of only  $(1-2) \times 10^{11} \text{ cm}^{-2} \text{ eV}^{-1}$  are measured for the best of our samples. (Edited author abstract) 4 refs.

**096103 Hg<sub>0.7</sub>Cd<sub>0.3</sub>Te/SiO<sub>2</sub>-PHOTOX INTERFACE PROPERTIES STUDIED BY PHOTO- AND BIAS-INDUCED CHARGING.** We have investigated the effects of light illumination in the wavelength range 1 μm to 2200 Angstrom (with and without DC bias) on the Hg<sub>0.7</sub>Cd<sub>0.3</sub>Te (n-type)/SiO<sub>2</sub>-Photox interface at 77 K in the metal-insulator-semiconductor device configuration. Illumination of wavelength λ without bias produced a flatband shift ( $\Delta U_{fb}$ ) towards positive values. The saturation value of  $\Delta U_{fb}$  has a pronounced peak at λ = 2800 Angstrom and is negligible for λ ≥ 5100 Angstrom. The

light-induced charge is maintained for at least 8 h at 77 K but leaks off if the device is heated briefly to 300 K. We propose a model to explain these results involving light-induced charging and discharging of very slow trap states in the Si 2-Photox (at or near the interface) with an energy distribution centered about 4.5 eV above the oxide valence band. (Edited author abstract) 9 refs.

## Spectroscopic Analysis

**096104 InP-SiO<sub>2</sub> METAL-INSULATOR-SEMICONDUCTOR STRUCTURE PARAMETERS INVESTIGATED WITH DLTS AND OTHER CAPACITANCE TECHNIQUES.** In this paper, we report the study of an n-type InP-SiO<sub>2</sub> Metal-Insulator-Semiconductor structure by means of Deep Level Transient Spectroscopy and two complementary techniques: Capacitance versus Voltage and Conductance versus Frequency measurements. We have observed two bulk traps probably related to impurities in the InP crystal. Majority carrier interface states have been studied: the three methods bring similar density profiles showing a minimum value about  $10^{12} \text{ eV}^{-1} \text{ cm}^{-2}$  in the energy range 0.4-0.7 eV below the conduction band edge. Moreover, we have detected a 'missing Phosphorus' interface level at 0.3 eV below the conduction band with a density about  $4 \times 10^{10} \text{ cm}^{-2}$ . (Author abstract) 15 refs.

**096105 INELASTIC ELECTRON TUNNELING SPECTROSCOPY OF Si MIS STRUCTURES WITH ULTRATHIN THERMAL SILICON NITRIDE AND THERMAL SILICA.** Inelastic electron tunneling spectroscopy (IETS) has proved useful for the study of the vibrational spectra of a range of molecular group compounds. In this technique the interaction between tunneling electrons and phonons including longitudinal and local-mode ones is used. Tunneling in boron-doped p-type silicon-insulator-semiconductor (MIS) tunnel junctions was studied at low temperatures by measuring the second derivative ( $d^2I/dU^2$ ) of the current voltage characteristics as a function of applied bias voltage (U). The vibrational spectra of the thermal silica and thermal silicon nitride was studied. (Edited author abstract.) 36 Refs.

## SEMICONDUCTOR DEVICES, MISFET

### Analysis

**096106 STUDIES ON AN In<sub>0.53</sub>Ga<sub>0.47</sub>As/In<sub>0.52</sub>Al<sub>0.48</sub>As SINGLE-QUANTUM-WELL QUASI-MISFET.** The authors describe the properties of a novel InGaAs/InAlAs quasi-MISFET in which an inverted modulation-doped single quantum well forms the channel and an undoped semi-insulating InAlAs constitutes the gate barrier. The entire structure is grown lattice-matched to InP continuously by molecular-beam epitaxy in a single step. Rapid thermal annealing of implanted semiconductors and ohmic contacts have been investigated and have been used successfully in the fabrication of the MISFETs. Improved performance is obtained with the incorporation of Ti in the source-drain metallization, with which contact resistances as low as 0.1 Ω mm are measured. 31 refs.

**Applications** See INTEGRATED CIRCUITS—Fabrication.

### Fabrication

**096107 Ga<sub>0.47</sub>In<sub>0.53</sub>As DEPLETION MODE MISFETs WITH NEGLIGIBLE DRAIN CURRENT DRIFT.** Ga<sub>0.47</sub>In<sub>0.53</sub>As depletion-mode metal insulator semiconductor field-effect transistors with a transconductance in the range 100-140 mS/mm and with no significant current drift (less than 3 percent in 30 hours) have been fabricated on epitaxial layers grown by MOCVD. This high performance has been achieved using an efficient passivation of the GaInAs surface which associates in situ native oxide removal by a hydrogen multipolar plasma and a Si<sub>3</sub>N<sub>4</sub> film deposition. (Author abstract.) 7 Refs.

Renaud, M. (Lab d'Electronique et de Physique Appliquee, Limeil Brevannes, Fr); Heyen, M.; Schmitz, Boher, P.; Schneider, J.; Barrier, J. *Electron Lett* v 24 n 12 Jun 9 1988 p 750-752.

**096108 In<sub>0.52</sub>Al<sub>0.48</sub>As/N<sup>+</sup>-In<sub>0.53</sub>Ga<sub>0.47</sub>As MISFET WITH A HEAVILY DOPED CHANNEL.** An In<sub>0.52</sub>Al<sub>0.48</sub>As/n<sup>+</sup>-In<sub>0.53</sub>Ga<sub>0.47</sub>As MIS-type field-effect transistor (FET) with a channel doped at a  $7 \times 10^{17} \text{ cm}^{-3}$  level has been fabricated on an InP substrate. A device with a 2-μm channel length has yielded a maximum transconductance of 152 mS/mm,  $f_T = 12.4 \text{ GHz}$ , and  $f_{max} = 50 \text{ GHz}$ . At 10 GHz, the maximum available gain is 17.4 dB. The performance of this device shows that heavily doped channel FETs are very promising for high-frequency operation. 17 refs.

Del Alamo, Jesus A. (NTT, Atsugi, Jpn); Mizutani, Takashi. *IEEE Electron Device Lett* v EDL-8 n 11 Nov 1987 p 534-536.

**096109 PSEUDOMORPHIC ZnSe/GaAs MISFET DEVICES.** ZnSe (a zincblende semiconductor with a room temperature bandgap of 2.7 eV) is used as the insulator in a working GaAs MISFET device. A coherent, dislocation-free ZnSe/GaAs heterointerface has been obtained by molecular-beam epitaxy (MBE) of pseudomorphic ZnSe onto as-grown GaAs MBE epilayers. The small (0.25%) lattice constant mismatch between ZnSe and GaAs allows for the growth of 1000-angstrom insulating layers devoid of strain-relieving misfit dislocations. Nucleation on MBE-grown epilayers results in a layer-by-layer growth. High-resolution transmission electron microscopy examining the interfacial region of the pseudomorphic ZnSe/GaAs epilayer heterojunction confirms the existence of the coherent interface such that the lattice constant in the plane of the layers is the same for the two materials. Having the capability of achieving a nearly perfect epitaxial interface has allowed for the fabrication of a GaAs MISFET device. MIS capacitors were used to determine the n-channel thickness and doping. The I-V characteristics of the MISFET devices were measured at room temperature and 77K. This II-VI/III-V heteroepitaxial interface has all the potential of the AlGaAs/GaAs structure with the additional advantage of larger band discontinuities.

**096110 HIGH-TRANSCONDUCTANCE HETEROSTRUCTURE Ga<sub>0.47</sub>In<sub>0.53</sub>As/InP METAL-INSULATOR-SEMICONDUCTOR FIELD-EFFECT TRANSISTORS GROWN BY CHEMICAL BEAM EPITAXY.** The SiO<sub>2</sub> insulator is on top of an InP layer; current transport occurs, however, in an adjacent n-type

Ga<sub>0.47</sub>In<sub>0.53</sub>As:Sn layer. A transconductance of  $g_m = 300$  mS/mm is obtained from depletion-mode MISFETs with a gate length of 1.2  $\mu$ m. This MIS (metal-insulator-semiconductor) junction has a symmetric current-voltage characteristic and a low leakage current of 10 nA at  $\pm 2$  V. High-frequency S-parameter measurements performed by probing devices on the wafers yield a unity current gain frequency of  $F_t = 22.2$  GHz and a maximum frequency of oscillation  $f_{max} = 27$  GHz. 8 refs.

**096111 p-CHANNEL QUANTUM-WELL HETEROSTRUCTURE MISFET.** A p-channel heterostructure MISFET-like device based on a quantum well with an underlying impurity layer is discussed. The device is based on an AlGaAs/GaAs heterostructure with a recessed-gate geometry and uses Zn-diffused refractory-metal contacts. The 4100 cm<sup>2</sup>/V-s hold mobility obtained in this inverted-interface structure at 77 K is comparable to that achieved in normal-interface AlGaAs/GaAs heterostructures. Transconductance and K-factor values as high as 52 mS/mm and 140 mS/V-mm, respectively, are obtained at 77 K in p-channel FETs with 2.0- $\mu$ m gate lengths and 6.0  $\mu$ m source-drain spacings, representing state-of-the-art values for p-HFETs at similar dimensions. 12 refs.

## Heterojunctions

**096112 HIGH-PERFORMANCE WN-GATE MISFETs FABRICATED FROM MOVPE WAFERS.** WN-gate heterojunction MISFETs with an AlGaAs layer as insulator have been fabricated on MOVPE wafers; they exhibit high transconductance (up to 460 mS/mm) and high  $V_t$  uniformity. (Author abstract) 5 refs.

Wolny, M. (Lab d'Electronique et de Physique Appliquee, Limel-Brevannes, Fr); Aguilu, T.; Deconinck, P.; Moroni, D.; Andre, J.P. *Electron Lett* v 23 n 21 Oct 8 1987 p 1127-1128.

## Materials

**096113 SHORT- AND LONG-TERM RELIABILITY OF NITRIDED OXIDE MISFETs.** The short- and long-term reliability of thin nitrided oxide (oxynitride) films is studied. Tests conducted on several oxynitride films fabricated under various nitridation conditions show that (1) the defect density of thin (5-nm) oxynitride film is very low; (2) oxynitride MISFETs exhibit less transconductance degradation due to hot-carrier injection than oxide MISFETs; (3) these thin films have superior time-dependent dielectric breakdown characteristics; and (4) the electron traps in oxynitride film are drastically reduced by annealing in an O<sub>2</sub> gas atmosphere. 4 refs.

## Radiation Effects

**096114 IONIZING RADIATION EFFECTS IN N-CHANNEL (HG,Cd)TE MISFETs WITH ANODIC SULFIDE PASSIVATION.** The effect of ionizing radiation, up to a dose of  $1.6 \times 10^5$  rad(ZnS), on n-channel (Hg,Cd)Te MISFETs, fabricated using anodic sulfide/ZnS insulators, has been investigated. Devices were irradiated under dc bias at 78K. Radiation-induced threshold-voltage shifts, degraded transconductance, and decreased subthreshold current gate voltage slopes were observed. For all but the most negative biases during irradiation threshold voltage shifts (a maximum of  $-6.0$  V at  $1.6 \times 10^5$  rad(ZnS)) are associated with net hole trapping with evidence for trapping near the interface for zero applied field during irradiation. Evidence of electron

trapping was observed for large negative biases during irradiation. The radiation-induced degradation in transconductance is attributed to surface mobility reduction (30% after  $1.6 \times 10^5$  rad(ZnS)) associated with scattering from interface charge. The decreased subthreshold slope (82 mV/decade at 50K after  $1.0 \times 10^5$  rad(ZnS)) is attributed to modification of the preirradiation gate voltage-surface-potential relationship by radiation-induced interface traps. 22 refs.

## Semiconductor Insulator Boundaries

**096115 InP METAL-INSULATOR-SEMICONDUCTOR FIELD-EFFECT TRANSISTORS USING VACUUM-EVAPORATED FILMS.** Because of high electron mobility in FETs using III-V compound semiconductors, extensive research has been made on these devices for high-speed logic circuits. Among these compound semiconductors, InP is suitable for the MIS FET unlike GaAs. This is because in InP the interface state is lower than  $10^{12}$  cm<sup>-2</sup> eV<sup>-1</sup> and the Fermi level at the interface is located near the conduction band. The characteristics of the interface between InP and an insulator was investigated using an MIS structure on an InP substrate fabricated by using vacuum-evaporated SiO or ZnS for the gate insulator and vacuum-evaporated aluminum for the gate electrode. The mobility of the device was influenced strongly by the activation temperature of the ion-implanted substrate. When the activation temperature was increased from 660°C to 700°C, the mobility decreased. This mobility decrease is considered to be due to Coulomb scattering in the channel. (Edited author abstract) 9 refs.

**096116 INTEL'S RADICAL REDESIGN DOUBLES 8096 THROUGHPUT.** Among various 16-bit microcontrollers a radically redesigned CMOS version of Intel's 8096 chip is introduced. The new 80C196 will double the performance of the 8096 in many applications, while adding new features that broaden design options. And for many math-intensive operations, throughput is tripled. The 1.5- $\mu$ m double-metal-CMOS 80C196 is a major departure from the earlier eight-bit 8051 and 16-bit 8096 - as severe as was the shift at the general-purpose microprocessor level from the 8- and 16-bit 8088/8086 to the present 16- and 32-bit 80286/80386 architectures. Pin- and code-compatible with the earlier 8096, the new 12-MHz 80C196 keeps many of the same features as its predecessors.

**096117 CAPACITANCE-VOLTAGE PROPERTIES OF THIN Ta<sub>2</sub>O<sub>5</sub> FILMS ON SILICON.** A comprehensive study of the high frequency (1 MHz) capacitance-voltage (C-V) properties of Al/Ta<sub>2</sub>O<sub>5</sub>/p-Si capacitors is described. The dependence of the dielectric constant of thermally oxidized Ta<sub>2</sub>O<sub>5</sub> on the oxidation temperature and the silicon substrate temperature during the deposition of tantalum metal was studied. Charge trapping or generation processes in the Ta<sub>2</sub>O<sub>5</sub> bulk or in the Ta<sub>2</sub>O<sub>5</sub>-Si interface region were investigated on the basis of shifts in the flat-band voltage of 1 MHz C-V curves. The Ta<sub>2</sub>O<sub>5</sub> thin films on p-type silicon substrates were prepared by thermal oxidation at 430-675°C of electron-beam-deposited tantalum. (Edited author abstract) 18 refs.

**096118 GENERATION CURRENTS FROM INTERFACE STATES IN SELECTIVELY IMPLANTED MOS STRUCTURES.** The ability to model the effects of doping on the depleted MOS surface velocity is particularly important for scaled devices because of high doping levels and high device susceptibility to generation currents. However, it is difficult to find detailed measurements of the influence of ion implantation on surface generation in the doping range  $3 \times 10^{16}$  to  $5 \times 10^{17}$  cm<sup>-3</sup>, and the data that have been reported are not all in agreement. This doping range is of practical importance for charge coupled devices. By careful design of test structures and by accurate 2-D modeling, we have investigated the effects of selective implantation on surface and bulk generation parameters for some arsenic and boron implants in this range into <100> p-type silicon. The principal results are that for arsenic implants below roughly  $6 \times 10^{12}$  cm<sup>-2</sup>, typical of buried channel implants, no enhancement of surface state generation is observed to within 20% of the nominal surface generation, despite concerns of arsenic segregation at the interface. Also, for boron implants below  $3 \times 10^{12}$  cm<sup>-2</sup>, typical of compensation implants in device active areas, no significant increase is observed. (Edited author abstract) 35 refs.

**096119 EFFECT OF GATE MATERIAL ON OXIDE DEGRADATION DUE TO CHARGE-INJECTION IN METAL-OXIDE-SEMICONDUCTOR CAPACITORS.** Aluminum and polycrystalline silicon gate metal-oxide-semiconductor (MOS) capacitors were studied in order to investigate the effect of the gate electrode material on the surface state generation and oxide trapping under tunneling injection of electrons into the oxide. Combined I-V and C-V measurements lead to the conclusion that the main differences between the two types of capacitors are in the surface states generation rate and saturation values and in the bulk trapping sites generation rate. The two types of devices display a remarkable similarity in the

behavior of the occupation probability of bulk oxide traps and in the initial number of trapping sites in fresh samples. (Author abstract) 21 refs.

**096120 SICHTBARE LICHTEMISSION BEI CMOS-KURZKANAL-INVERTERN.** [Visible Light Emission of Short-Channel CMOS Inverters]. Visible light emission of both, the n-channel and the p-channel field-effect transistor of a short-channel CMOS inverter has been observed. The emitted light has a very weak intensity and appears quite uniform along the drain ends of the channels. A direct correlation between the emitted light intensity and the anomalous transfer behavior is shown, as it occurs in CMOS circuits at higher supply voltages. (Author abstract) In German. 7 refs.

**096121 CHARACTERISTICS OF A SET OF 12.7-MM PROCESSOR CHIPS.** A 1.0- $\mu$ m CMOS technology with three layers of metal is used to implement a high-density master image that contains logic and RAM's. The image allows the use of more than 1,000,000 transistors. A hierarchical design methodology is described. This chip offers variable-sized physical partitions and RAM macros. Fixed area sizes and locations for partitions and macros are not necessary. Density and performance of custom chips are approached by the described methodology with significantly lower development cost and time. 4 refs.

**096123 RECOMBINATION LIFETIME OF SHORT-BASE-WIDTH DEVICES USING THE PULSED MOS CAPACITOR TECHNIQUE.** The authors point out that the technique of D.K. Schroder, J.D. Whitfield, and C.J. Varker for the determination of recombination lifetime using pulsed MOS capacitors at elevated temperatures does not consider lateral quasi-neutral bulk generation and the time dependence of the width of the space-charge region in short-base-width devices (i.e., epitaxial wafers). Consequently, calculations using this technique indicate that the recombination lifetime is a function of device diameter. A simple one-dimensional approach is proposed in which bulk generation in the lateral area of the device is taken into consideration resulting in a fairly uniform recombination lifetime that is independent of the device diameter for short-base-width devices. 5 refs.

**096124 CHARACTERISTICS OF CMOS DEVICES**

**IN OXYGEN-IMPLANTED SILICON-ON-INSULATOR STRUCTURES.** The characteristics of CMOS devices fabricated in oxygen-implanted silicon-on-insulator (SOI) substrates with different oxygen doses are studied. The results show that transistor junction leakage currents are improved by orders of magnitude when the oxygen dose is decreased from  $2.25 \times 10^{18} \text{ cm}^{-2}$  to  $1.4 \times 10^{18} \text{ cm}^{-2}$ . The floating-body effect, i.e., transistor turn-on at lower gate voltage with dramatic improvement in subthreshold slope when the drain voltage is increased, is enhanced by the reduction in leakage current and hence the oxygen dose. In SOI substrates implanted with  $1.4 \times 10^{18} \text{ cm}^{-2}$  oxygen dose and annealed at 1150°C, back-channel mobilities are decreased by several orders of magnitude compared to the mobilities in the precipitate-free silicon film. These device characteristics are correlated with the microstructure at the silicon-buried-oxide interface, which is controlled by oxygen implantation and post-oxygen-implantation anneal. 17 refs.

**096125 CMOS TEMPERATURE-COMPENSATED CURRENT REFERENCE.** A temperature-compensated current reference for CMOS integrated circuits based on a MOSFET as current-defining element, is described. To minimize the mass-production cost, it uses no external components nor trimming procedures. Comparison with classical current references with a resistor as a current-defining element shows a considerable improvement of the relative tolerance on the current. Theoretical expressions are presented and compared with experimental results from an integrated prototype. For devices from the same batch, the standard deviation is measured to be 2.5%, and the temperature dependence is 3% from 0 to 80°C. From theoretical equations, the standard deviation of devices from different batches is expected to be about 15%. 7 refs.

**096126 ADVANCED OSELO ISOLATION WITH SHALLOW GROOVES FOR HIGH-SPEED SUBMICROMETER ULSI'S.** A submicrometer (0.7- $\mu$ m) isolation structure using processes that are compatible with the LOCOS processes has been developed. This novel isolation structure, called OSELO II, is fabricated using modified local oxidation technology and an offset structure. The offset structure is characterized by a framed Si<sub>3</sub>N<sub>4</sub> mask for bird-beak-free oxidation, formation of shallow self-aligned Si grooves, and two-step boron-ion implantation that decreases current leakage along the isolation sidewall. This isolation technology provides (1) an active MOS transistor having a mask-defined 0.8- $\mu$ m channel width giving 60% more drain current than the conventional transistor with LOCOS isolation, (2) 0.6- $\mu$ m minimum isolation length, which equals the isolation length between the two adjacent active transistors and is also defined by the mask length, and (3) 20% lower parasitic junction capacitance compared with the LOCOS structure. These results demonstrate that the process is promising for high-speed submicrometer ultralarge-scale integrated devices. 8 refs.

**096128 THREE-DIMENSIONAL ANALYSIS PROGRAM FOR MOS DEVICES AND THE VIRTUAL NODE METHOD.** A three-dimensional finite difference program has been developed for the analysis of steady-state characteristics of MOS devices with arbitrary geometric boundary shapes. A self-consistent solution of Poisson's equation and the current continuity equations by use of Gummel's approach has been carried out. The Newton-Raphson algorithm was used for the linearization of the discretized Poisson equation, and an ICCG method was employed for the solution of the resulting linear equations. By reasonably controlling the number of Newton iterations, selecting a suitable LU decomposition for the linearized system matrix by use of the ICCG method, and by using the results of a two-dimensional analysis as initial values, the required computational time can be kept acceptably short. In order to use the finite difference method for MOS devices with complex shapes, a new approach called the Virtual Node Method was developed. Theoretical analysis and the computational results indicate that this approach works satisfactorily for MOS devices with arbitrary shapes. (Author abstract) 7 refs.

**096129 COMMON ORIGIN FOR ELECTRON AND HOLE TRAPS IN MOS DEVICES.** Experimental evidence is provided to show that many electron and hole traps found in ultraclean and annealed SiO<sub>2</sub> layers are related to intrinsic oxygen-deficiency defects. These trapping sites are found to play a dominant role in low-field oxide breakdown, radiation sensitivity, and interface state generation in MOS devices. The saturation of SiO<sub>2</sub> with oxygen leads to the elimination of a large number of these traps and to the stabilization of SiO<sub>2</sub> layers for use in submicrometer devices. 22 refs.

**096130 CMOS VLSI SETS THE DIRECTION FOR NEW ICS.** A few years ago, CMOS was just a curiosity. A technology developed primarily to meet extremely low power consumption and radiation-tolerance requirements, CMOS became infamous for its high cost, its tendency to latch up, and its insatiable appetite for real estate. Then US and Japanese manufacturers began to work on 1-Mbit DRAMS. CMOS is reborn, reaching skyrocketing speed and unprecedented density and spawning new classes of

function-, application-, and user-defined ICs. Meanwhile, emphasis for designers is shifting from process to applications expertise.

Wilson, Ron (Computer Design, Littleton, MA, USA). *Comput Des* v 26 n 22 Dec 1987 p 79-82, 86-91.

**096131 BICMOS FOR HIGH PERFORMANCE, HIGH DENSITY APPLICATIONS.** The applicability of BICMOS is investigated with respect to technology, circuit design and system aspects. Based on a n-well CMOS technology, process extensions like buried layer and polysilicon emitter are discussed with regard to bipolar device performance. The Totem Pole buffer, a basic BICMOS circuit, is investigated in detail. Finally we point out the advantages of BICMOS compared to both Bipolar and CMOS using more complex circuits (SRAMs). (Edited author abstract) 5 refs.

Klar, Heinrich (Siemens AG, Munich, West Ger); Heimsch, Wolfgang; Klose, Helmut; Krebs, Roland; Pfaffel, Bruno; Stegherr, Michael; Winerl, Josef; Ziemann, Klaus. *AEU Arch Elektron Uebertrag Electron Commun* v 42 n 2 Mar-Apr 1988 p 65-74.

**096132 IS BICMOS THE NEXT TECHNOLOGY DRIVER?** BICMOS, a process combining bipolar and CMOS transistors on the same die, has been the subject of extensive research and development that now appears to be bearing fruit. It is becoming a favorite candidate for mainstream products: interface logic, static random-access memories, mixed analog/digital circuits, and gate arrays. It is even being considered for high-performance microprocessors and dynamic RAMs. Some observers say the process will be the main technology driving virtually all functions in the next decade; others believe it will always remain in niche applications.

Cole, Bernard C. *Electronics* v 61 n 3 Feb 4 1988 p 55-57.

**096133 ALTERA'S SPEEDY WAY TO TAILOR ADD-ONS TO IBM'S PS/2.** Add-on board suppliers will soon get an all-in-one programmable interface chip that will help them quickly enter the potentially huge market for plug-in peripheral cards serving IBM Corp's Personal System/2. Altera Corp. is launching the industry's first erasable programmable logic device aimed at providing complete interface to the IBM Micro Channel bus. Not only will the new CMOS EPLD save time in turning out the add-on boards, but it will save board space as well. Accompanying development software will cut the time to market even more, and vendors will be able to put their add-on PS/2 interface functions into four reserved programmable spaces on the EPLD.

Lineback, J. Robert. *Electronics* v 61 n 4 Feb 18 1988 p 99-100.

**096134 DEVICE CHARACTERISTICS OF THE Pd-SnO<sub>x</sub> MIS OXYGEN SENSORS.** An oxygen sensor has been developed in the device configuration Pd-SnO<sub>x</sub>-Si<sub>3</sub>N<sub>4</sub>-SiO<sub>2</sub>-Si-Al with highly resistive SnO<sub>x</sub> film as oxygen absorptive element. The device operation is based on a shift in flat-band voltage  $\Delta V_{fb}$  of a MIS (metal-insulator-semiconductor) capacitor on oxygen adsorption. The device sensitivity, i.e.,  $\Delta V_{fb}$  shift, was investigated as a function of structural and chemical composition of the absorptive SnO<sub>x</sub> film. Typical results for the columnar SnO<sub>x</sub> film showed  $\Delta V_{fb}$  to be 100 mV at T = 19°C in 0.5-torr O<sub>2</sub> partial pressure, and at T = 80°C  $\Delta V_{fb}$  increased to 200 mV. Under the same condition, devices with continuous SnO<sub>x</sub> film had  $\Delta V_{fb}$  of 15 and 50 mV, respectively, indicating much higher sensitivity for columnar SnO<sub>x</sub> film. The effect of external field on oxygen adsorption clearly indicates that O<sub>2</sub> adsorption is almost completely suppressed at the external bias of +18 V for the investigated range of O<sub>2</sub> pressure. This property eliminates the necessity of keeping the device under vacuum or encapsulation before use.

Xu, J.F. (Rutgers Univ, Piscataway, NJ, USA); Kang, W.P.; Lalevic, B.; Poteat, T.L. *IEEE Trans Electron Devices* v ED-34 n 11 Nov 1987, 45th Annu Device Res Conf, Santa Barbara, CA, USA, Jun 22-24 1987 p 2383.

**096135 MOS IMPLEMENTATION OF TOTALLY SELF-CHECKING CHECKER FOR THE 1-OUT-OF-3 CODE.** The problem of designing a totally self-checking (TSC) checker for the 1-out-of-3 code using combinational logic alone has not yet been solved. It is shown, however, that it is feasible to design such a checker in MOS technology. Analysis and simulation show that the proposed checker is a TSC checker for the 1-out-of-3 code with respect to a set of physical defects which occur frequently in MOS technology. 10 refs.

Tao, D.L. (Syracuse Univ, NY, USA); Lala, Parag K.; Hartmann, Carlos R.P. *IEEE J Solid State Circuits* v 23 n 3 Jun 1988, Thirteenth Eur Solid-State Circuits Conf 87, Bad Soden, West Ger, Sep 1987 p 875-877.

**096136 PALLADIUM-GATE MOS DEVICES FOR ARSINE DETECTION.** Pd-MOS structures with holes in the gate metal have been prepared for detecting arsine, and investigated in a flow system. The samples show a reversible decrease of threshold voltage on admixtures of arsine to an air stream (temperature range 350 K to 470 K). A change of threshold voltage of 34 mV is found for 0.1 ppm arsine in air (T = 433 K). For arsine concentrations of 2.5 ppm, a response time of 40 s and a recovery time of 300 s are observed at 450 K. The response of the same structures to small concentrations of H<sub>2</sub> has also been investigated. Sensitivity and response are comparable to the results found for arsine. This similarity points to a decomposition of arsine at the Pd surface, with subsequent diffusion of hydrogen to the metal-oxide interface. (Author abstract) 13 refs.

**096137 PARAMETRIC FORMULATION OF CMOS LATCH-UP AS A FUNCTION OF CHIP LAYOUT PARAMETERS.** The relationship between the CMOS latch-up characteristics and the chip layout parameters such as the location and spacing of the well and substrate tie-ups (straps) is studied. By measuring the strap current  $I_s$  at varying distances from the well-substrate boundary, it is found that placing these straps at the boundary is most effective. The holding current  $I_h(x, N)$  at a point in the circuit is quantitatively related to 1) the distance x of the well-substrate strap from this point, and 2) the doping level N of the respective region. An analytical expression of the form  $I_h(x, N) = e^{a-bx} = I_{oc} - bx$  is developed to predict the required frequency of strapping for a particular process technology, where coefficients a and b are functions of the doping. The impact of a strapping scheme on latch-up is explained in terms of a simple engineering model. 12 refs.

**096138 TWO-STAGE CHANNEL ROUTING FOR CMOS GATE ARRAYS.** A two-stage channel routing technique for CMOS gate arrays is proposed. In the first stage, certain nets are routed on two sides of the channel so that channel density is reduced. A single-side O(N) optimum algorithm is presented for this stage. The algorithm can choose one set with maximum weight from among the possible sets of routing nets. The second stage can be general channel routing. An efficient algorithm for a one-and-a-half-layer routing model that is based on one metal mask and a fixed poly-crossunder layer is presented. This router scans the channel in a left-to-right,

zone-by-zone manner, using a multilevel prediction to guide wiring and a greedy approach for nets to contend for limited crossunders. Implementation results are provided to indicate the efficiency of the technique. 16 refs.

**096139 CMOS GATE FOREST: AN EFFICIENT AND FLEXIBLE HIGH-PERFORMANCE ASIC DESIGN ENVIRONMENT.** The basic concepts of the second-generation gate arrays are described. The most important architectures that were used to implement the different concepts are discussed. An overview of the current status of a number of typical sea-of-gates masters is given. A number of quality marks have been defined along which the different architectures can be evaluated. These quality marks range from microarchitecture aspects such as isolation techniques and connectability of the core cells, to macro aspects such as distribution functions. Using these quality marks for reference, the Gate Forest is discussed. The Gate Forest is seen as a major extension of the sea-of-gates principle. It differs from the extant sea-of-gates concept in several important aspects. It is based on a hierarchical concept, both in architecture and design. It combines flexibility and efficiency in one environment by providing transistor-level optimization together with cell library support for different logic design styles. It furthermore supports the efficient implementation of different types of memory in any desired location. The current status of the second generation of the Gate Forest is also briefly described. 28 refs.

**096140 DETERMINISTIC ALGORITHM FOR AUTOMATIC CMOS TRANSISTOR SIZING.** A model which offers a closed-form equation for determining device size, based on speed and load, has been developed. The need for circuit simulation is eliminated in most cases. This model is used in a system for automatically producing performance-tuned cell layouts. 6 refs.

Richman, Bruce A. (Gould Inc, Pocatello, ID, USA); Hansen, James E.; Cameron, Kelly. *IEEE J Solid State Circuits* v 23 n 2 Apr 1988 p 522-526.

**096141 MOSIS - A GATEWAY TO SILICON.** The MOSIS Service, a low-cost prototyping service for standard-cell and full-custom VLSI circuit development, is discussed. MOSIS (an acronym for MOS Implementation System) has developed a methodology that allows the merging of many different projects from various organizations onto one wafer. This cost-sharing gives designers opportunities that might be prohibitive at regular commercial prices. Since designs are combined on a single mask set, MOSIS users pay for only the fraction of the silicon that they use. Runs are scheduled on a regular basis for 3.0-, 2.0-, 1.6-, and 1.2- $\mu$ m double-metal CMOS/bulk technologies. MOSIS quality control and access to MOSIS are described.

**Computer Interfaces**

**096142 TI TO ROLL OUT ITS FIRST FAMILY OF PRODUCTS MADE WITH BICMOS.** A brand new family of interface chips is introduced by Texas Instruments that are notable for two important reasons: These ICs run cooler than any other high-performance interface chips, delivering bipolar speeds at CMOS power levels. The devices are made with a new process based on Impact, TI's mainstream high-performance bipolar technology, which has been modified to accept CMOS on the same substrate. The result is Impact CS. The company has big plans for its biCMOS process: it will use it across the board, building memories, gate arrays, application-specific ICs and even linear circuits.

**Computer Simulation** See Also LOGIC CIRCUITS—Mathematical Models.

**096143 THRESHOLD VOLTAGE PREDICTIONS FROM MICROMOS: A 3-D MOS SIMULATOR.** This paper provides predicted values of threshold voltage for the full recessed MOS structure obtained from the 3-D code called MICROMOS. Uniform and implanted channel cases are considered. Short channel, narrow width and small geometry effects are automatically included. Results for these conditions as well as variable oxide thickness and substrate doping are shown. All results indicate the correct tendency of change for threshold voltage. Values for threshold voltage prediction are obtained from 3-D computer generated drain current vs gate voltage characteristics. (Edited author abstract) 9 refs.

**096145 LATCHUP PERFORMANCE OF RETROGRADE AND CONVENTIONAL N-WELL CMOS TECHNOLOGIES.** The static and transient latchup performance of conventional and retrograde n-well CMOS technologies is compared. Both technologies are optimized for 1- $\mu$ m design-rule circuit applications and have comparable well depths under the active area. The devices are fabricated on both bulk silicon and p-on-p+ epitaxial silicon substrates, allowing the influence of the n-well doping profile and the effect of the interaction between the fabrication schedule and the epitaxial material to be studied. The retrograde n-well structures are shown to have superior latchup immunity, due primarily to reduced n-well sheet resistance and greater tolerance to thin p on p+ epitaxial material. 15 refs.

## Control

**096147 EVOLUTION OF MOS-BIPOLAR POWER SEMICONDUCTOR TECHNOLOGY.** A review of the innovations that have led to the evolution of a power transistor technology based on MOS gate control is provided. This technology offers the advantage of very high input impedance, which allows the control of the devices using low-cost integrated circuits. The physics of operation of the two types of devices in this category,

power MOSFETs and power MOS-bipolar devices, are described. Trends in process technology and device ratings are analyzed. Based on the superior performance of these devices, it is projected that they will completely displace the power bipolar transistor in the future. 29 refs.

**Degradation** See Also SEMICONDUCTING SILICON—Defects.

**096148 MNOS DEGRADATION MECHANISM.** For over 10 years, there has been much research on MNOS structure degradation in connection with developments in energy-independent MOS memory components with stable characteristics. Degradation makes itself felt in metal-silicon nitride (SN)-ultrathin oxide-semiconductor (MNOS) structures in that there are changes in charge-accumulation characteristics for electrons and holes at the trapping centers (TC) as well as in the charge flow characteristics in repeated read-write cycles, as well as on UV irradiation (the accumulated charge is less, as is the storage time). In this paper conductivity changes have been observed in SN MNOS structures as related to the charge passing. The rates of conductivity change in the two materials are determined by the nonequilibrium-carrier concentrations in the bulk and are dependent on the manufacturing conditions. 22 refs.

**096149 TIME-DEPENDENT EVOLUTION OF INTERFACE TRAPS IN HOT-ELECTRON DAMAGED METAL/SiO<sub>2</sub>/SI CAPACITORS.** Results are reported which indicate that the interface traps generated by hot-electron injection undergo significant changes with time at room temperature. Immediately after injection, a peak of the interface trap distribution appears above the midgap energy about 0.75 eV above the valence-band energy level (approx.  $E_v + 0.75$  eV) in all of the samples studied. This peak, along with its background, increases or decreases with time at room temperature, depending on the gate bias polarity during injection, the initial damage level, the gate-induced stress, and the presence of certain chemical impurities in the gate oxide. In the cases where this peak decreases with time, a second peak below midgap (approx.  $E_v + 0.35$  eV) develops, and this peak grows with time at the expense of the first peak. The important factors that affect the time-dependent behavior of the interface traps are discussed. 9 refs.

**096150 NEW HOT-CARRIER-INDUCED DEGRADATION PHENOMENA IN HALF-MICROMETER MOS TRANSISTORS.** The degradation magnitude is one to two orders larger than that of the severest stress condition ever reported, and increases rapidly with decreasing gate length. This phenomenon limits the applicable voltage for 0.5- $\mu$ m MOSFETs. The mechanism of this large degradation has been determined using experimental data and simulation results. The large degradation is due to the highly efficient injection of hot electrons into the gate oxide. The degradation magnitude has a positive strong correlation with gate currents instead of substrate currents over a wide range of bias voltage. From these results and two-dimensional two-carrier device simulations, it has been determined that the large degradation is caused by the large impact ionization just at the Si/SiO<sub>2</sub> interface in the source high-resistivity region (source impact), and by the high electric field enhancing the hot-electron injection of hot electrons into the gate oxide, resulting in the large degradation. Moreover, the magnitude of the new degradation mode increases rapidly with decreasing the gate length to 0.5  $\mu$ m. So, it becomes extremely important to suppress this degradation mode in the design of reliable 0.5- $\mu$ m MOSFETs. Some methods of suppressing this degradation are presented and discussed. 4 refs.

**096151 DRAMATIC IMPROVEMENT OF HOT-ELECTRON-INDUCED INTERFACE DEGRADATION IN MOS STRUCTURES CONTAINING F OR CL IN SiO<sub>2</sub>.** The effects of F and Cl incorporated in SiO<sub>2</sub> on the susceptibility of the metal/SiO<sub>2</sub> (MOS) interface to hot-electron damage have been studied. It has been found that, by introducing a very small amount of F or Cl in the thermal SiO<sub>2</sub>, the generation of interface traps by Fowler-Nordheim tunneled hot electrons can be greatly suppressed. In addition, the gate-size dependence of hot-electron-induced interface traps, which is normally observed in samples made of dry oxides, does not appear in such chlorinated or fluorinated samples. When excess amounts of F or Cl are introduced into SiO<sub>2</sub>, however, the benefits mentioned will diminish. The possible roles that F and Cl play that lead to the experimental observations are discussed. 10 refs.

Nishioka, Yasuhiro (Yale Univ, New Haven, CT, USA); Da Silva, Eronides F. Jr.; Wang, Yu; Ma, Tso-Ping. *IEEE Electron Device Lett* v 9 n 1 Jan 1988 p 38-40.

**096152 CHARGE STORAGE IN MOS STRUCTURES AS AFFECTED BY AVALANCHE- AND PHOTOINJECTION.** Experimental data are presented for charge storage in dry SiO<sub>2</sub> of silicon MOS structures, which accompanies electron avalanche- and photoinjection. Dependencies of the effect on prehistory, temperature and field were investigated. Dominant positive charging of nonhydrated structures at 300 K and a field  $\geq 2$  MV/cm were observed. Its characteristic time was found by means of pulse photoinjection. The results obtained are discussed in terms of indirect energy dissipation of hot electrons in SiO<sub>2</sub>. (Author abstract) 6 refs.

**096153 CMOS LATCHUP MODELLING: A NEW APPROACH.** In this paper, a new lumped element latchup model which includes two extra bipolar transistors is proposed. The divergence between the results of the conventional and the proposed model is explained in terms of the circuit parameters. The output behavior of CMOS latchup and the output latchup mode are discussed in connection with the proposed model and the predictions of the model are compared to the results of the conventional model using SPICE. (Author abstract) 10 refs.

Li, Wei (Univ of Pittsburgh, Pittsburgh, PA, USA); El Nokali, M. *Int J Electron* v 64 n 2 Feb 1988 p 269-282.

**096154 WALLS COME TUMBLING DOWN.** Next year an increasing number of semiconductor firms will begin to introduce standard, semicustom and custom products based on next-generation CMOS processes with 0.8- to 1- $\mu$ m design rules, blurring the demarcation between exotic high-performance technology and standard commercial applications. Also coming soon are the first samples of 4-Mbit dynamic RAMs, and the first

experimental 16-Mbit designs. Merging of logic and bit memory blocks is contemplated that will help boost system performance.

Cole, Bernard C. *Electronics* v 60 n 21 Oct 15 1987 p 95-97.

**096155 OPTIMIZED LAYOUT OF MOS CELLS.** A design method using both logical optimization and optimized topological arrangements is described. Starting from a minimized Boolean function, a synthesis of an optimized well-structured network is obtained. The most original aspect of this approach is a transistor merging procedure leading to a nonseries-parallel network while maintaining a systematic layout. An extension to the synthesis of several functions relies on transistor mergings between functions and allows comparisons to a PLA implementation. Gains in both area and performance are obtained. 16 refs.

**096156 SELF-TERMINATING LOW-VOLTAGE SWING CMOS OUTPUT DRIVER.** A CMOS output pad driver circuit is described that automatically series-terminates a driven line in the line's characteristic impedance. The circuit has advantages in speed, power, and size over conventional designs. The key idea is the use of emitter-coupled logic (ECL)-compatible low-voltage swings for signaling, combined with the use of the driver transistor as both a switch and as a termination resistor. An on-chip measurement circuit dynamically adjusts the impedance of the driver to match the impedance of an external reference impedance standard, allowing the circuit to compensate for both chip and board level fabrication variations. 6 refs.

Knight, Thomas F. Jr. (Symbolics Inc, Cambridge, MA, USA); Krymm, Alexander. *IEEE J Solid State Circuits* v 23 n 2 Apr 1988 p 457-464.

**096157 DESIGN AND IMPLEMENTATION OF A CMOS VCXO FOR FM STEREO DECODERS.** A circuit technique to simulate large variable capacitance of both positive and negative polarities over a given frequency range is discussed. The simulated capacitance can be varied by voltage control from  $-60$  to  $+100$  pF. The capacitor-simulating circuit is connected in parallel with a resonator to tune its parallel resonance. An oscillator with grounded resonator is also developed. Together with the variable capacitor, a voltage-controlled crystal oscillator (VCXO) is realized. The oscillation frequency of the oscillator can be varied  $\pm 1\%$  by voltage control. Detailed analyses to completely characterize the oscillator with simple expression are presented. The prototype of the VCXO has been fabricated in a  $4\text{-}\mu\text{m}$  standard CMOS process. 7 refs.

## Electric Breakdown

**096158 ULTRA-THIN SILICON-DIOXIDE BREAKDOWN CHARACTERISTICS OF MOS DEVICES WITH  $N^+$  AND  $P^+$  POLYSILICON GATES.** The authors investigated the effect of the gate material on the breakdown characteristics of ultrathin silicon dioxide films at low voltages ( $< 6$  V). When MOS capacitors were stressed with a positive gate voltage, the charge-to-breakdown and time-to-breakdown at a fixed oxide-voltage drop were significantly smaller in  $p^+$  polysilicon-gate capacitors than  $n^+$  polysilicon-gate capacitors. The results are interpreted in terms of a simple model of hole tunneling resulting from hot-hole generation in the anode by hot electrons entering from the silicon dioxide. Extrapolation of high-voltage-breakdown life-time measurements for relatively thick-oxide devices to low voltages may be complicated by this mechanism. 12 refs.

**096159 ON THE INFLUENCE OF THE THIN INTERFACIAL OXIDE LAYER ON THE ELECTRICAL AND PHOTOVOLTAIC PROPERTIES OF Au/OXIDE/ $p$ -InP DIODES.** Au/thermal oxide/ $p$ -InP structures were investigated for the oxide layer thickness,  $\delta$ , ranging from 1.8 to 13.5 nm. For increasing  $\delta$ , the forward dark-current mechanism changed from thermionic emission into recombination, and tunneling became dominant in reverse current. Under illumination the short-circuit current remained almost independent of  $\delta$  up to 10 nm and an important increase of the open-circuit voltage occurred at  $\delta \geq 4.5$  nm. Auger spectroscopy revealed that the outer part of the interfacial layer was  $\text{In}_2\text{O}_3$  while the inner part contained In, O and P. An energy band scheme was proposed for this two-layer model, which allowed us to explain the electrical characteristics. (Author abstract) 20 refs.

**096161 PSEUDOCOLLECTOR EFFECT IN A CMOS INVERTER.** The pseudocollector effect in a CMOS inverter is demonstrated by analyzing the current distribution in the latchup state. The decoupling of the current flow from the latchup feedback loop is controlled by the input voltage applied to the gates of  $n$ -channel and  $p$ -channel MOSFETs, which results in a reduction of latchup susceptibility. Latchup in a CMOS inverter is influenced by the effects of input voltage through a pseudocollector and potential modulation. It is shown that a simple SCR structure cannot reflect adequately these phenomena. 5 refs.

**Electronic Properties** See Also TRANSISTORS, FIELD EFFECT—Electric Properties.

**096162 HOT ELECTRON EFFECTS IN NARROW WIDTH MOS DEVICES.** Narrow channel NMOSFET device degradation is explored by measuring the effect of hot-carrier stress on the current-voltage characteristics, the transconductance, field-effect mobility and surface scattering factor. Under conditions of substrate electron injection, the degradation mechanism can be explained as being interface charge generation, resulting in an increase on the surface scattering factor. This effect is more pronounced in narrow channel devices due to an excess hot-electron activity along the edges of the channel where the in-diffusion of field implant creates a region with higher impurity concentration. (Author abstract) 10 refs.

**096163 DEVELOPMENT OF HOT-CARRIER SIMULATOR  $\text{H}_2$ -CAST AND ITS APPLICATION TO LDD.** A hot-carrier simulator ( $\text{H}_2$ -CAST) is developed using the 'effective electron temperature model,' and with

this simulator, the lightly doped drain (LDD) structure is analyzed. This simulator is based on a 3-D device simulator, where the carrier motion in the oxide film is also considered. The model equation for the channel hot electron region and the avalanche hot electron region in the NMOS single-drain structure is evaluated. It is found that the model is valid for an analysis of the hot-carrier injection phenomena in both regions. From the analysis of the LDD structure, it is apparent that the injection of the avalanche hot-holes is responsible for the degradation of the device characteristic. This simulator is considered to be an effective tool in designing a device with an effective channel length  $L_{\text{eff}}$  less than  $0.8\text{ }\mu\text{m}$ . (Edited author abstract) 15 refs.

**096164 REDUCED OXIDE CHARGE TRAPPING AND IMPROVED HOT-ELECTRON RELIABILITY IN SUBMICROMETER MOS DEVICES FABRICATED BY TITANIUM SALICIDE PROCESS.** The effects of the titanium salicide (self-aligned silicide) process on the reliability of very-thin-gate-oxide MOSFETs have been studied. It is shown that the titanium salicide process, as compared to the conventional poly-Si gate process, has reduced electron and hole trapping in the oxide and improved hot-electron reliability. It is shown that these phenomena are related to the reduced hydrogen content in the oxide as revealed by a secondary ion mass spectrometry (SIMS) analysis. 10 refs.

Chang, Shuo-Tung (Hewlett-Packard Lab, Palo Alto, CA, USA); Chiu, Kuang Yi. *IEEE Electron Device Lett* v 9 n 5 May 1988 p 244-246.

**096165 EFFECT OF HYDROGEN ON TRAP GENERATION, POSITIVE CHARGE TRAPPING, AND TIME-DEPENDENT DIELECTRIC BREAKDOWN OF GATE OXIDES.** The effect of high-temperature ( $\approx 900^\circ\text{C}$ ) hydrogen on the gate oxides of MOS devices is studied. Hydrogen is introduced into devices by either high-temperature anneal or conventional process steps such as low-pressure chemical vapor deposition (LPCVD) of  $\text{Si}_3\text{N}_4$ . In all cases, measurements of high-field stress behavior show that high-temperature hydrogen steps reduce time to breakdown and increase bulk and interface trap generation, but do not affect the generation of positive charge. These results indicate that the wear-out mechanism of gate oxides at high fields is related to trap generation rather than to accumulation of positive charge. 10 refs.

Nissan-Cohen, Y. (GE, Schenectady, NY, USA); Gorczyca, T. *IEEE Electron Device Lett* v 9 n 6 Feb 1988, 34th Nucl Sci Symp, San Francisco, CA, USA, Oct 21-23 1987 p 287-289.

**096166 VALENCE BAND ELECTRON TUNNELING IN METAL-OXIDE-SILICON STRUCTURES.** Experimental results are presented for the substrate current appearing in thin oxide metal-oxide-silicon capacitors with a shallow  $n/p$  junction beneath the gate when a positive gate voltage in the tunneling regime is applied. The analysis of the current-voltage characteristics shows that for an oxide voltage drop lower than about 5 V the substrate current is due to electron tunneling from the silicon valence band. The dispersion relation in the energy range extending 3 eV below the oxide conduction band is determined from the voltage dependence of the current in the direct tunneling regime. An effective mass of about  $0.8m_0$  is found near the edge of the oxide conduction band, while for lower energies a strong decrease of the effective mass is observed. (Author abstract) 6 refs.

Modelli, A. (SGS Microelettronica, Agrate, Italy). *Appl Surf Sci* (1985) v 30 n 1-4 Oct II 1987, INFOS 87: Proc of the Fifth Int Conf on Insul Films on Semicond, Louvain, Belg, Apr 13-15 1987 p 298-303.

**096167 MODELS AND EXPERIMENTS ON DEGRADATION OF OXIDIZED SILICON.** The concepts of electronic and protonic traps are introduced to delineate and classify the fundamental mechanisms of charging, generation, annealing and hydrogenation of electronic or electron and hole traps located in the interfacial (gate-conductor/oxide, oxide/nitride and oxide/silicon), insulator (oxide, nitride and oxynitride) and semiconductor surface layers of silicon MOS transistors and integrated circuits. Two matrix tables, one without tunneling ( $3 \times 3$ ) and one with tunneling ( $3 \times 4$ ) are used to classify the trap charging and electronic injection mechanisms according to the initial and final (band or bound) states of the electronic transition and the energy exchange mechanisms (thermal, optical and Auger-impact). The importance of tunneling to and from traps (TTT) as an oxide charge build-up mechanism is discussed. Examples at three DC bias conditions to delineate the dominant degradation mechanisms in silicon MOS transistors are given. (Edited author abstract)

**096168 EVALUATION OF CHANNEL HOT CARRIER EFFECTS IN n-MOS TRANSISTORS AT 77 K WITH THE CHARGE PUMPING TECHNIQUE.** With the charge pumping technique, the role of hot holes in the channel hot carrier degradation of short channel n-MOS transistors is shown to be less pronounced at 77 K than at 300 K. Also fewer fast interface states are generated at 77 K for the same substrate current level in the low gate bias regime. Furthermore, the dominant device degradation is found to be in the high gate bias regime. Furthermore, the dominant device degradation is found to be in the high gate bias regime at 77 K, in contrast to the case of 300 K. This is due to the presence of negative charge in the oxide or in acceptor-type interface states. (Author abstract) 6 refs.

## Etching

**096170 OXIDE BREAKDOWN DUE TO CHARGE ACCUMULATION DURING PLASMA ETCHING.** Charge accumulation on an insulating gate oxide may cause electrostatic breakdown. Exposing a wafer containing MOS devices to a plasma discharge during patterning of poly gate structures may, under certain conditions, cause damage to the device due to such a charge accumulation. At 13.56 MHz the charge that can be transferred to the wafer is so small that it is unlikely that the gate will reach a level where electrical breakdown will occur. If, however, the frequency is low or a dc supply is used, breakdown of the oxides may appear. Samples subjected to a low frequency or dc plasma also exhibit an increase in the density of states at the oxide semiconductor interface. (Edited author abstract) 9 refs.

**Fabrication** See Also DATA PROCESSING—Data Acquisition; INTEGRATED CIRCUITS, LINEAR—Fabrication; INTEGRATED CIRCUITS, LSI—Fabrication; INTEGRATED CIRCUITS, VLSI—Fabrication; SEMICONDUCTOR DEVICES, BIPOLAR—Fabrication; SEMICONDUCTOR DEVICES, MOSFET—Fabrication; TELEPHONE EXCHANGES—Electronic Equipment.

**096173 INTERFACE PROPERTIES OF THERMAL SiO<sub>2</sub> USING 1,1,1,TRICHLOROETHANE(TCA). TRICHLOROETHANE(TCA).** 1,1,1,Trichloroethane (TCA) has been used as a chlorine source in growing gate oxides for MOS devices. These oxides were grown with varying molar concentrations of TCA. Interface trap density ( $D_{it}$ ) was evaluated as a function of molar concentration of TCA. Results were compared with trichloroethylene (TCE) oxides, grown under identical conditions, to assess the feasibility of substituting a TCA source for the TCE. It was found that TCA oxides showed reduced interface trap density,  $D_{it}$ , for an optimum molar concentration of TCA, as compared to TCE oxides. In addition, interface trap density  $D_{it}$  vs. molar concentration of TCA shows a broadened minimum. It was also found that TCA is a better source for p-type silicon, than for n-type silicon. (Author abstract) 12 refs.

**096174 HIGH-PERFORMANCE BICMOS TECHNOLOGY WITH DOUBLE-POLYSILICON SELF-ALIGNED BIPOLAR DEVICES.** A high-performance BiCMOS (bipolar complementary MOS) technology is described which incorporates 12-GHz double-polysilicon self-aligned bipolar, fully silicided CMOS devices and 1- $\mu$ m features. This process is applied to a BiCMOS gate design, called transistor feedback logic, to fabricate a divide-by-16 frequency divider with a maximum operating frequency of 364 MHz. Availability of uncompromised MOS and bipolar transistors allows a free mix of pure CMOS, pure bipolar, or BiCMOS gates on the same chip. 16 refs.

**096175 SI-GATE CMOS DEVICES ON A Si/CaF<sub>2</sub>/Si STRUCTURE.** Si-gate CMOS inverter chains and 1/8 dynamic frequency dividers have been fabricated on a

Si/CaF<sub>2</sub>/Si structure. A high-quality heteroepitaxial Si/CaF<sub>2</sub>/Si structure was formed by successive molecular-beam epitaxy of CaF<sub>2</sub> and Si. Transistors have been fabricated with an improved CMOS process that prevents crystal degradation during the fabrication process as much as possible. The maximum effective mobilities are about 570 and 240 cm<sup>2</sup>/V-s for n-channel and p-channel transistors, respectively. The inverter chain, with an effective channel length of 2.0  $\mu$ m, has a delay time per gate of 360 ps. A maximum operating frequency of 300 MHz is obtained in the divider with an effective channel length of 2.5  $\mu$ m at a supply voltage of 5 V. These results indicate that the Si/CaF<sub>2</sub>/Si structure has potential for the fabrication of high-speed silicon-on-insulator devices. 13 refs.

**096178 UPMOS - A NEW APPROACH TO SUBMICROMETER VLSI.** A self-aligned, raised contact structure, UPMOS, which provides shallow junctions, low series resistance, and minimizes the source/drain (S/D) junction capacitance for MOS circuits is described. In this process, a composite gate structure with a 'reaction layer' and SiO<sub>2</sub> sidewalls is patterned by conventional RSE techniques. A layer of undoped polysilicon  $\approx 0.2 \mu$ m-0.3  $\mu$ m thick is then deposited over the entire wafer. This polysilicon layer is removed from areas other than the S/D in two steps. The S/D junctions are formed by ion implantation into the polysilicon followed by a diffusion anneal. A selective CoSi<sub>2</sub> layer is then formed on the polysilicon to reduce sheet resistance. This produces a MOSFET structure with raised S/D regions that extend over the field oxide for contact to first-level metal. Contacts to the S/D junction made on the polysilicon over the field oxide provide a more reliable contact scheme by avoiding aluminum spiking and relaxing alignment tolerances. This structure greatly reduces the S/D junction area and thus reduces the junction capacitance. In

addition, the formation of shallow junctions without implant damage is made possible with the UPMOS structure. 1 ref.

**096179 PROCESS FOR A CMOS CHANNEL-STOP IMPLANTATION SELF-ALIGNED TO THE P-WELL AND P-WELL ACTIVE AREA.** A simplified isolation process for test CMOS LSI chip fabrication is proposed. In the process, channel-stop implantation is self-aligned to the p-well and the p-well active area. It is shown that a CMOS device with a one-level metallization can be fabricated with only seven photomasks using the process. 5 refs.

Yamauchi, Noriyoshi (NTT, Tokai, Jpn). *IEEE Trans Electron Devices* v ED-34 n 12 Dec 1987, 1987 IEEE Microwave and Millimeter-Wave Monolithic Circuits Symp, Jun 8-9 1987 p 2562-2563.

**096180 PROCESS FOR THE COMBINED FABRICATION OF ION SENSORS AND CMOS CIRCUITS.** A novel process for the fabrication of ion-selective field-effect transistors (ISFETs) together with CMOS circuits on the same chip is reported. The process is based on a standard 2- $\mu$ m, n-well, CMOS process, which is only modified starting at the metal interconnect step. The interconnect layer used is tungsten silicide. ISFETs are fabricated with floating polysilicon gates, which are exposed to photolithographic masking and HF etching before silicon nitride is deposited on the wafer. This layer of  $\text{Si}_3\text{N}_4$  acts both as the pH-sensitive insulator for the ISFETs and as a protection layer for the on-chip circuitry buried beneath it. A source-follower circuit is described that provides an output voltage dependent on the threshold-voltage variations of the sensing transistor. 15 refs.

## Heat Treatment

**096181 EFFECT OF 1300-1380°C ANNEAL TEMPERATURES AND MATERIAL CONTAMINATION ON THE CHARACTERISTICS OF CMOS/SIMOX DEVICES.** The characteristics of CMOS transistors fabricated on silicon implanted with oxygen (SIMOX) materials were measured as a function of the silicon superficial layer contamination levels. In addition, postimplant anneal temperatures of 1300°C, 1350°C, and 1380°C were examined. It is found that the transistor leakage currents as well as the integrity of the gate oxide and implanted SIMOX oxide are functions of the carbon content in the starting material. Leakage currents below  $1.0 \times 10^{-12}$  A/ $\mu$ m of channel width have been measured when the carbon concentration is reduced to  $2 \times 10^{18}$  /cm<sup>2</sup>. In addition, the integrity of the transistor gate dielectric, SIMOX implanted oxide, and oxygen precipitate density are seen to be a function of the postimplant anneal temperature. A gate dielectric breakdown field of 10 MV/cm has been achieved when the postimplant temperature is increased to 1380°C. 8 refs.

## Hysteresis

**096182 HYSTERESIS CYCLE IN THE LATCH-UP CHARACTERISTIC OF WIDE CMOS STRUCTURES.** Experimental results are interpreted in terms of a simple lumped-element model that is also used to reproduce the hysteresis phenomenon with discrete components. The hysteresis is related to a three-dimensional (3-D) nonuniformity in the current distribution. Such hysteresis can lead to an erroneous evaluation of latchup parameters, such as the holding current density. 2 refs.

## Ion Implantation

**096183 EFFECTS OF FIELD IMPLANTS ON SMALL GEOMETRY CMOS DEVICES.** Various aspects of field implants have been studied with reference to a 3  $\mu$ m CMOS p-well process. It has been found that p-field (adjacent to p-channel transistors) implant is not required for a low voltage (1.5 v) process. Both p- and n-field implants are, however, essential for a high voltage (5 v) process. The threshold voltage or a narrow width n-channel transistor is found to be increased from 0.3 v to 2.5 v as compared to that of a large width transistor if the field implant is followed by a long high temperature step. The increase in threshold in the case of a narrow p-channel transistor is observed to be from 0.35 to 1.65 v under the same conditions. Such a large increase in the threshold voltage can be prevented by a proper design of the process. It has also been observed that arsenic is an unsuitable species of p-field implants. (Edited author abstract) 18 refs.

**096184 ADJUSTMENT OF THRESHOLD VOLTAGE OF MOS DEVICES BY ION IMPLANTATION.** We report the effect of oxide thickness, implant energy and dose on threshold voltage shift  $\Delta V_t$ . The implant parameters e.g. stopping power, projected range, straggle and the energy loss per micron for an ion in the substrate lattice are calculated using WKB potential. The junction depth beneath the oxide semiconductor surface is calculated using a two layer model. The parameters are used in theoretical calculation of threshold shift of MOS devices. Experimental threshold voltages for unimplanted and implanted samples were obtained from C-V plots, showing good agreement with theory. (Edited author abstract) 7 refs.

## Junctions

**096185 INTERFACE STATES AND IMPURITIES IN MOS STRUCTURES WITH VERY THIN TUNNELING BARRIERS.** Electron tunneling spectroscopy was used to investigate MOS junctions with very thin silicon oxide or silicon oxynitride layers (2-5 nm) as tunneling barriers. For the tunneling measurements at 4.2 K highly degenerate P-doped ( $3 \times 10^{20}$  cm<sup>-3</sup>) Si substrates, oxidized in dry oxygen at 600°C were used. Silicon oxynitride layers were prepared by plasma nitridation in an  $\text{NH}_3$  discharge. As gate electrodes evaporated films of Al, Au or Pb were utilized. Changes in the tunneling conductivity were attributed to changes in the density of interface states, caused by hydrogen annealing or by high field stress. The results indicate a correlation between the generation of interface states and the removal of Si-H configurations. Vibrational modes of phonons, dopants and impurities were detected by inelastic electron tunneling spectroscopy. (Author abstract) 16 refs.

**096189 TIME PERTURBATION ANALYSIS FOR THE MOS SYSTEM.** The development of a numerical implementation of the small signal response of the MOS (Metal-Oxide-Silicon) capacitor using time perturbation analysis is discussed. The effects of nonconstant doping profiles and interface and bulk traps are included. The model uses Fermi-Dirac statistics to describe the occupancy of the interface and bulk traps. The oxide region is considered to have no mobile carriers and any fixed oxide charge distribution is modeled as a charge sheet at the Si-SiO<sub>2</sub> interface. This technique can be used to find the small signal response of the device from the static solution. (Author abstract) 10 refs.

**096190 EXTRACTION OF TERMINAL CHARGES FROM TWO-DIMENSIONAL DEVICE SIMULATIONS OF MOS TRANSISTORS.** Quasi-static models of n-terminal semiconductor devices usually express terminal currents as the sum of steady-state and transient components. We consider here the formulation where these transient components are assumed to be time derivatives of charges associated with the terminals and these charges are completely specified by the terminal voltages applied to the device. This paper describes a method for extracting these terminal charges from two-dimensional device simulations of MOS transistors. The technique was used to obtain terminal charges for an n-channel MOS transistor and some results are presented. In addition, charge tables were generated and used in a table model for MOS transistors. The transient behavior of a circuit using this table model is compared with a physical time-domain simulation. (Author abstract) 10 refs.

**096191 DESIGN OPTIMIZATION OF JCMOS STRUCTURES.** JCMOS structures are based on merging an MOS capacitance, a JFET, and a bipolar transistor in the area of a single MOS transistor. The structure performs the basic operations of temporary storage, writing, and sensing of stored data and is used in DRAM, serial dynamic memory, and dynamic logic applications.

A JCMOS structure implementation using a retrograde p-well CMOS process is presented. An analytical model relating terminal voltages and currents to device dimensions and doping levels is derived. Simulation results are presented for both reading and writing modes of operation. A test cell was successfully fabricated to verify the principle of operation, and experimental and theoretical results are compared. A simplified lumped component equivalent circuit, to be used in circuit simulators such as SPICE, is presented, and its validity is investigated. The structure design requirements and procedure are presented. The model is used to optimize the design of the structure. 17 refs.

**096192 EFFECT OF CHANNEL IMPLANTS ON MOS TRANSISTOR CHARACTERIZATION.** MOS device characterization involves the extraction of parameters from electrical measurements. A nonuniform channel doping profile can make such characterization ambiguous since device parameters are usually based upon a uniform doping profile model. The authors solve the one-dimensional Poisson's equation for several doping profiles and show the impact of a nonuniform doping profile on the threshold surface potential, threshold voltage, normal field mobility degradation, and transconductance. Five methods - the linear extrapolation, transconductance peak, Fowler and Hartstein, constant current, and split C-V methods - for obtaining the threshold voltage are compared. 22 refs.

**096193 APPLIED FIELD AND TOTAL DOSE DEPENDENCE OF TRAPPED CHARGE BUILDUP IN MOS DEVICES.** A rate equation for charge buildup is developed that includes carrier sweep out, geminate recombination, hole/electron trapping, and effects of internal fields. The first moment of the resulting charge distribution is calculated to yield the midgap voltage shift as a function of irradiation time. The initial midgap voltage shift per dose and the maximum midgap voltage shift are derived. The field dependence of these quantities is shown to be a consequence of the field dependence of the hole/electron capture cross sections and geminate recombination escape probability. The results of this formulation show that the  $E^{-1/2}$  decrease in the midgap shift per dose with field described in the literature is due to the decrease of the hole capture cross section with increasing applied field. The theory is validated by comparison with experimental results obtained on 225-angstrom thermal oxide on p-type silicon test capacitors irradiated under bias at room temperature. 26 refs.

**096195 METHODOLOGY FOR SUBMICRON DEVICE MODEL DEVELOPMENT.** Two-dimensional (2-D) device analysis is coupled into a new model development environment. An improved set of 2-D analytical boundary conditions for submicron MOS technology is developed through using exact information from numerical simulations. In addition to the accurate modeling of 2-D potential boundary conditions, the model provides a framework for further enhancements in the context of technology evolution. Specifically, the methodology is general and can be extended to a variety of technologically complex submicron structures, for example, source/drain tip implants (LDD-type devices) and a variety of other blanket and locally implanted structures. 12 refs.

**096196 COMPUTATION OF STEADY-STATE CMOS LATCHUP CHARACTERISTICS.** Robust computational techniques are presented for steady-state characterization of CMOS latchup via numerical device simulation. Of specific interest are efficient means of accurately evaluating knees in I-V characteristics, corresponding to latchup triggering and holding points. Making use of predictor-corrector continuation procedures and special initial-guess strategies, more than an order of magnitude improvement in computational efficiency is achieved over previous approaches. It is shown that for some latchup problems, these methods are essential due to their unique ability to trace characteristics that are multivalued in both I and V. Simulated results for both triggering and holding characteristics of a VLSI CMOS process are presented, from which primary structural dependencies are identified and new physical insight is obtained. 38 refs.

**096197 MOS TRANSISTOR CHARGE MODEL FOR VLSI DESIGN.** The development of an MOS transistor charge and capacitance model for the analysis and design of VLSI circuits is described. The total stored charge in each of the gate, bulk, and channel regions is obtained by integrating the distributed charge densities over the thin-oxide area. Charge conservation is guaranteed in this model by using the terminal charges as the state variables. The capacitance expressions have the nonreciprocal property. Partition of channel charge into the drain and source components is 40/60 in the saturation region. In the triode region, this partition changes asymptotically to 50/50 as the gate voltage increases. The carrier-velocity saturation effect is incorporated through both the modification of channel quasi-Fermi level and the determination of drain saturation voltage. Implementation of the model in the SPICE circuit simulator has been achieved. Modeled results compare well with experimental data for transistors with channel lengths as small as 0.75  $\mu$ m. 30 refs.

**096202 ACCURACY OF CONVENTIONAL INVERSION CHARGE MODELING IN SCALED DOWN MOS DEVICES.** The density of surface inversion charge in MOS structures is typically calculated using the relation  $Q = \text{cox} (V_G - V_T)$ . We try to quantitatively assess the goodness of this relation in MOS devices scaled down according to constant field scaling and constant voltage scaling principles by comparing the inversion charge given by this relation to the inversion charge obtained by numerically solving the Poisson equation in one dimension. It turns out that while in the case of constant field scaling the conventional relation for inver-

sion charge becomes progressively erroneous, the same is not true for devices scaled down according to constant voltage scaling. (Edited author abstract) 5 refs.

**096203 LOGARITHMIC KINETIC FOR THE ACCUMULATION OF IONIC CHARGE IN  $\text{SiO}_2$  DIELECTRIC FILMS.** Ion drift and accumulation of an ionic charge  $Q$  in dielectric films of  $\text{SiO}_2$ , as a rule, correspond to diffusion theory which gives a time dependence of the form  $Q \propto (t/\tau)^{1/2}$ , where  $t$  is the time of action of the polarizing voltage and  $\tau$  is a constant of the process. Hofstein observed an exponential dependence  $Q \propto 1 - \exp(-t/\tau)$  which was explained by the emission of ions from traps near the dielectric-metal interface. In the present work it was found that charge accumulation in  $\text{SiO}_2$  films can follow a law  $Q \propto \ln(t/\tau)$ . A modification of the existing models is needed for an explanation of such kinetics. 4 refs.

**Noise, Spurious Signal**

**096206 INFLUENCE OF THE INTERFACE AND OF THE CHANNEL VOLUME OF  $1/f$  NOISE OF MOS TRANSISTORS BIASED IN THE LINEAR REGION AT STRONG INVERSION.** The paper is concerned with  $1/f$  noise of MOS transistors operating in the linear region at strong inversion. It is assumed that the  $1/f$  noise can be caused by carrier density fluctuations and/or carrier mobility fluctuations in the channel. A theoretical analysis and experimental investigation indicate that in general the equivalent input noise voltage level  $S_{Vg}$  and the shape of the characteristics of  $S_{Vg}$  vs the effective gate voltage  $V_{GT}$  depend on the transistor geometry, on the surface state density vs energy distribution  $N_t(E_f)$ , and on the scattering centre density vs channel depth  $N_s(x)$ . In the case of larger transistors (long channel and large oxide thickness) carrier density fluctuations determine the  $S_{Vg}$  level and the distribution  $N_t(E_f)$  determines the shape of  $S_{Vg}$  vs  $V_{GT}$ . In the case of smaller transistors, the shape of the characteristics  $S_{Vg}$  vs  $V_{GT}$  can also be determined by carrier mobility fluctuations. (Author abstract) 15 refs.

**Optimization**

**096208 LINEAR ALGORITHMS FOR OPTIMIZING THE LAYOUT OF DYNAMIC CMOS CELLS.** In many CMOS design styles the basic building blocks are complex (static or dynamic) CMOS gates with up to a few dozen transistors. The layout optimization for such gates takes the shape of graph optimization problems. Two such graph problems, corresponding to different layout styles for basic cells composed of dynamic CMOS gates, are considered. Both problems are solved in linear time; the number of gates in the cell is considered. 16 refs.

**096209 OPTIMIZED  $1.0\text{-}\mu\text{m}$  CMOS TECHNOLOGY FOR NEXT-GENERATION CHANNELLESS GATE ARRAYS.** An optimized 5-V  $1.0\text{-}\mu\text{m}$  CMOS technology has been developed to achieve high speed and high packing density for channelless gate arrays. In addition to the downward scaling of CMOS device geometry, reduction of the parasitic resistances is essential for next-generation channelless gate arrays. The technology utilizes sidewalled PMOS and lightly doped drain (LDD) NMOS structures with  $1.0\text{-}\mu\text{m}$  actual physical gate lengths and  $20\text{-nm}$  gate-oxide thickness. Tungsten metal is selectively deposited on the source and drain regions to reduce sheet resistivity, thus gaining extra speed improvement. This technology was applied to a large-scale gate array of over 40K usable gates; high-speed (290-ps) operation has been achieved for a two-input NAND gate with a fan-out of 2 and  $2\text{-mm}$  Al. An advanced graphic processor with over 35K used gates has been successfully demonstrated. 11 refs.

**Physical Properties**

**096212 EFFECTS OF HYDROGEN CHLORIDE ON THE ANNEALING KINETICS OF INTERFACE AND OXIDE TRAPS IN OXIDIZED SILICON STRESSED BY AVALANCHE ELECTRON INJECTION.** Effects of HCl during oxidation on the room temperature annealing kinetics of interface and oxide traps are investigated in aluminum/poly-silicon/oxide/silicon capacitors after avalanche electron injection (AEI) from silicon. A turn-around phenomenon in the interface trap annealing kinetics is observed in the HCl oxides, which may be associated with the activation of a chlorine-related interface trap after the AEI ceases. HCl reduces or retards the anneal of the interface traps but enhance the anneal of the oxide traps. In a  $200\text{ A}$  oxide, an exposure to  $10^{15}\text{ e/cm}^2$  of 8-keV electrons gave much larger annealed densities of oxide and interface traps than in an oxide stressed by avalanche injected electrons of  $10^{18}\text{ e/cm}^2$  of an equivalent amount of energy with initial gate voltage in the 22-25 V range. (Edited author abstract) 18 refs.

**096214 BURIED-OXIDE ISOLATION WITH ETCH-STOP (BOXES).** A buried-oxide (BOX) isolation process which has greatly improved submicrometer MOS manufacturability has been developed. The process, BOXES (BOX with etch-stop) isolation, incorporates an etch-stop layer over active area down to which the field oxide is etched, rather than to the active-area surface as in BOX. Nonuniformities inherent to the BOX process do not then cause the field oxide to be recessed below the active-area surface. Furthermore, by a brief overetch of the etch-stop during its patterning, the field oxide is made to controllably encroach laterally over the active-area edges. Measurements of NMOS devices demonstrate that BOXES isolation with lateral encroachment has greatly reduced sidewall and edge parasitic conduction. 7 refs.

## Radiation Damage

**096215 CORRELATION BETWEEN MECHANICAL STRESS AND HYDROGEN-RELATED EFFECTS ON RADIATION-INDUCED DAMAGE IN MOS STRUCTURES.** Polycide-gate MOS capacitors were investigated as a function of gate-oxide thickness. The compressive stress magnitude was altered by varying the silicide (TiSi<sub>2</sub> or WSi<sub>2</sub>) thickness in the polycide-gate electrode, and hydrogen introduction into gate-SiO<sub>2</sub> film was carried out by diffusion from plasma-deposited silicon-nitride passivation film (SiN-cap). In a MOS capacitor without passivation film (no-cap sample), it was found that compressive stress on gate-SiO<sub>2</sub> reduces both positive charge build-up ( $\Delta Q_p$ ) and interface-trap generation ( $\Delta D_{it}$ ). Radiation induced shift,  $Q_{ox}$  exhibits a smaller stress effect as compared with  $D_{it}$ . As gate-SiO<sub>2</sub> thickness decreases, the stress effect on  $\delta Q_{ot}$  increases, while this effect on  $D_{it}$  remains nearly constant. Both stress effects of  $Q_{ox}$  and  $D_{it}$  in SiN-cap samples show a gate-oxide-thickness dependence similar to that on  $Q_{ox}$  in no-cap samples. The stress effect observed in no-cap samples can be explained on the basis of the bond reformation process at the SiO<sub>2</sub>/Si interface and near the electrode/SiO<sub>2</sub> interface. 22 refs.

**096216 CHARGE COLLECTION EFFICIENCY RELATED TO DAMAGE IN MOS CAPACITORS.** Absolute charge collection efficiencies of undamaged and radiation-damaged MOS capacitors have been measured as a function of applied collection bias and related to device damage. The measurements were performed on devices irradiated to various particle fluences, under different bias conditions, and with both lightly and heavily damaging particles. The measurements allow characterization and separation of damage effects due to flatband voltage shifts and atomic displacements in the substrate, and are sensitive indicators of both kinds of damage. Using this technique in conjunction with a microbeam, possibilities exist for investigating damage at a highly localized level, ion per ion, as the damage occurs. This technique is not limited to MOS devices. 8 refs.

**096218 TOTAL-DOSE EFFECTS OF GAMMA-RAY IRRADIATION ON CMOS/SIMOX DEVICES.** Radiation-hardened CMOS/SIMOX (separation by implanted oxygen) devices have been developed using a combination of vertical isolation structures obtained by SIMOX technology and recently developed lateral isolation structures. The n-channel MOSFET is vertically isolated by multilayers of highly-oxygen-doped polysilicon and buried SiO<sub>2</sub>; it is laterally isolated by multilayers of thin sidewall SiO<sub>2</sub>, sidewall polysilicon, and

thick field SiO<sub>2</sub>. The p-channel MOSFET has the same vertical isolation structure as that of the n-channel MOSFET, but has no sidewall polysilicon layer and uses a thick field SiO<sub>2</sub> layer for lateral isolation. Highly-oxygen-doped polysilicon and sidewall polysilicon layers act to shield radiation-induced positive charges trapped in the buried SiO<sub>2</sub> and field SiO<sub>2</sub> layers, respectively. 9 refs.

**096220 ROLE OF HYDROGEN IN RADIATION-INDUCED DEFECT FORMATION IN POLYSILICON GATE MOS DEVICES.** The role of hydrogen in the generation of radiation-induced interface-trap and oxide-trapped charge in MOS polysilicon gate capacitors has been investigated. The concentration of radiation-induced interface-trap and oxide-trapped charge measured both immediately after irradiation and after postirradiation anneal increases if high-temperature anneals are performed in hydrogen. These results were analyzed in the context of several models of interface-trap and oxide-trapped charge formation. The mutual increase in the concentration of oxide-trapped charge and the early-time (1-ms to 10-sec) component of interface-trap charge with the amount of hydrogen used during processing suggests that the breaking of Si-H or Si-OH bonds may be responsible for much of the defect formation at or near the silicon/silicon dioxide interface. 30 refs.

**096221 CRITICAL EVALUATION OF THE MIDGAP-VOLTAGE-SHIFT METHOD FOR DETERMINING OXIDE TRAPPED CHARGE IN IRRADIATED MOS DEVICES.** The validity of using midgap voltage shifts to determine radiation-induced oxide-trapped charge is examined using thermally stimulated current (TSC), conductance, and C-V techniques. The assumption behind the midgap technique that all interface states are amphoteric P<sub>b</sub> centers is shown to be not generally valid. Conductance measurements revealed a donor interface state in the upper half of the bandgap. Results obtained by combining data from TSC and high-frequency C-V measurements show the existence of three types of radiation-induced interface states: the P<sub>b</sub> center, a donor state in the upper half of the bandgap, and an acceptor state in the lower half. No single surface potential exists that is the neutral point for N<sub>it</sub> for all processes and radiation doses. Midgap voltage shifts do not generally correlate with oxide-trapped charge determined from thermally stimulated current (TSC) measurements. The magnitude of the fractional deviation is typically less than a factor of unity but in some cases is as large as a factor of four. The significance of these errors needs to be determined for each application. Arguments and tests supporting the validity of using TSC measurements for determining oxide-trapped charge are presented. 21 refs.

**096222 RADIATION-INDUCED INTERFACE TRAPS IN MO/SiO<sub>2</sub>/SI CAPACITORS.** The radiation induced interface traps in molybdenum-gate metal/SiO<sub>2</sub>/Si (MOS) capacitors over a wide range of radiation doses have been investigated. It has been found that: (1) high-temperature (900°C) annealing in H<sub>2</sub> after Mo deposition increases the radiation sensitivity significantly, especially for dose levels above 1 Mrad(Si); (2) gate-size dependence of the radiation sensitivity is observed in samples without the hydrogen anneal, but not in samples annealed in hydrogen; (3) a characteristic interface trap peak above midgap appears immediately after irradiation, which, along with its background, decreases with time after irradiation over a long period (over 1000 h) at room temperature; (4) the rate of decrease of this peak is a function of the initial damage level, the gate bias during sample storage, and the storage temperature; (5) while this peak is decreasing, a second peak below midgap will develop and grow with time, and the rate of growth of the second peak is correlatable to the reduction of the first peak, suggesting the possibility of defect transformation process at the interface; (6) the defect transformation process is strongly influenced by the gate bias and sample temperature after irradiation. 11 refs.

**096223 GROWTH AND ANNEALING OF TRAPPED HOLES AND INTERFACE STATES USING TIME-DEPENDENT BIASES.** Defect growth and annealing mechanisms in MOS devices have been studied. Biases were changed during irradiations. Significant radiation-induced annealing of trapped holes was observed. Apparent room-temperature annealing of interface states was also observed. A consistent explanation of this apparent annealing is presented, i.e., an effect of LNUs (lateral nonuniformities) on the results of the sub-threshold analysis technique. A possible physical mechanism for the creation of LNUs due to inhomogeneous energy deposition is explored. 29 refs.

**096224 RADIATION RESPONSE OF MOS CAPACITORS CONTAINING FLUORINATED OXIDES.** By introducing small amounts of fluorine into the gate oxide, the radiation response of metal/SiO<sub>2</sub>/Si(MOS) capacitors and their subsequent time-dependent behavior were altered. It was observed that compared with their control capacitors, which had no fluorine introduced into the oxide, the fluorinated samples exhibit the following major differences: (1) the densities of radiation-induced oxide charge and interface traps are reduced, (2) the gate-size dependence of the radiation-induced interface traps is suppressed, and (3) the overall density of the radiation-induced interface traps continues to decrease with time for many hours after irradiation before a turnaround trend is observed. Possible mechanisms involving the roles that fluorine may play in relieving the oxide strain near the SiO<sub>2</sub>/Si interface and in the postirradiation defect-reaction chemistry are discussed. 17 refs.

**096225 COMPARISON OF POSITIVE CHARGE GENERATION IN HIGH FIELD STRESSING AND IONIZING RADIATION ON MOS STRUCTURES.** The effects of ionizing radiation and high field stressing on metal-oxide-silicon oxides are compared. Using electron spin resonance, the authors compare the point defects responsible for the positive charge generated by ionizing radiation and high field stressing. The two processes have been found to be different in that the positive charge generated by ionizing radiation is almost entirely due to E' centers in the oxide; however, less than half the positive charge generated by high field stressing can be accounted for by E' centers. 17 refs.

(AT&T Bell Lab, Allentown, PA, USA); Desko, John C.; Kohler, Ross A.; Lawrence, Cris W.; Nagy, William J.; Shimer, Julie A.; Steenwyk, Steven D.; Anderson, Richard E.; Fu, Julia S. *IEEE Trans Nucl Sci* v NS-34 n 6 Dec 1987, 1987 Annu Conf on Nucl and Space Radiat Eff, Snowmass Village, CO, USA, Jul 28-31 1987 p 1460-1463.

**096227 MEASUREMENT OF LOW-ENERGY X-RAY DOSE ENHANCEMENT IN MOS DEVICES WITH METAL SILICIDE GATES.** A photocurrent technique was used to accurately measure dose enhancement in the gate oxide of MOS devices with tungsten or titanium silicide over various thicknesses of poly-Si exposed to low-energy X-irradiation. The results show that the dose enhancement is strongly dependent on the type of metal/silicide used and the thickness of the poly-Si layer between the metal/silicide and the SiO<sub>2</sub> gate insulator. A straightforward procedure for calculating the equal damage dose equivalence for metal/silicide over poly-Si gate MOS structures is presented. 10 refs.

**096228 VARIATIONS IN SEMICONDUCTOR DEVICE RESPONSE IN A MEDIUM-ENERGY X-RAY DOSE-ENHANCING ENVIRONMENT.** Experiments were undertaken to investigate the response of semiconductor devices to medium-energy X-ray irradiation under conditions in which dose-enhancement effects are important. It has been found that the response of MOS capacitors to the same dose-enhanced radiation depends not only on the increased dose, but also on the incident radiation spectra, device temperature and processing, and/or oxide thickness and electric field. In many cases, these dependencies cannot be explained simply in terms of existing knowledge of basic mechanisms of radiation effects on MOS devices (for example, electron-hole recombination and hole transport and trapping), or by present Monte Carlo electron/photon transport codes such as the Integrated Tiger Series (ITS). The response of semiconductor diodes to the dose-enhanced radiation appears to be qualitatively different from that of MOS capacitors, and differs markedly in value from the ITS code predictions. These results demonstrate that an improved understanding of semiconductor device response to enhanced irradiation is needed to assure simulation fidelity of tests of devices to be used in dose-enhancing environments. 26 refs.

**096230 EFFECTIVENESS OF CMOS CHARGE REFLECTION BARRIERS IN SPACE RADIATION ENVIRONMENTS.** Single-event upsets in microelectronic circuits follow the collection of more than some critical amount of charge at certain reverse-biased junctions. Reducing charge collection at the junctions lowers the upset rate without requiring performance tradeoff. Three mechanisms for reducing the fraction of charge collected at a junction can be incorporated in the use of CMOS-type wells. For illustration, the CHMOS-III-D process used in Intel's P51C256 is shown to lower the error rate to be expected in deep space by an order of magnitude from that calculated for an equivalent dynamic RAM of standard design. 8 refs.

**096231 RESIDUAL CHARGES EFFECT ON THE ANNEALING BEHAVIOR OF Co-60 IRRADIATED MOS CAPACITORS.** It was experimentally observed that the residual charges of an MOS capacitor after C-V testing can exist for a long time. These charges include a nonzero field at the SiO<sub>2</sub>/Si interface, and subsequently affect the annealing behavior due to a charge-temperature effect if the MOS capacitor is left floating during annealing. This problem is solved by a flat-band condition annealing method based on a charge-temperature technique. The annealing kinetics of a Co-60 irradiated MOS capacitor are then studied. A power-law behavior of the annealing kinetics has been obtained for oxide charges annealed at 300°C. Possible explanations are given for this observation. 20 refs.

## Semiconductor Insulator Boundaries

**096235 OBSERVATION OF FERMIL LEVEL PINNING AT THE GaAs-PLASMA-OXIDE INTERFACE.** Small-signal charge transient spectroscopy (CTS) measurements of GaAs MOS diodes with plasma oxide insulating layers point to two dominant trapping levels responsible for the steady-state Fermi level pinning at the GaAs-oxide interface. The E<sub>c</sub>-0.70 eV discrete surface trap is identified with the defect level observed in fundamental studies of III-V surfaces; this defect is due to missing As. The second level, positioned at E<sub>c</sub>-0.67 eV, has not been reported previously. It is argued that the 0.67 eV defect is characteristic of the transition layer between the moderately doped (N<sub>D</sub> to about 10<sup>15</sup>-10<sup>16</sup> cm<sup>-3</sup>) GaAs substrate and the oxide. (Author abstract) 18 refs.

**096236 STUDY OF ELECTRON TRAPS IN SILICON DIOXIDE DUE TO MOBILE SODIUM IONS AT THE Si-SiO<sub>2</sub> INTERFACE.** We have studied electron trapping due to mobile sodium ions in silicon dioxide near the Si-SiO<sub>2</sub> interface using MOS capacitors. After doing a bias-temperature stress, hot electrons were injected into SiO<sub>2</sub> by avalanche injection. The number of trapped electrons, as measured by shifts in flat-band voltage of high frequency C-V curves, is proportional to the sodium ion density. The depth of these electron traps was found by a thermal detrapping experiment to be about 1.2 eV. A possible model for the origin of the mobile sodium-related electron trap is presented. (Author abstract) 16 refs.

**096237 ELECTRICAL PROPERTIES OF Si-SiO<sub>2</sub> STRUCTURES TREATED IN HELIUM PLASMA.** Experimental data are presented for the influence of helium plasma on the electrical properties of Si-SiO<sub>2</sub> structures with dry thermal oxide (d = 16 - 72 nm). It is found that for strongly damaged structures low temperature helium plasma introduces acceptor-type interface

states near the conduction band edge and has an annealing effect on the deep acceptor-type states. It has also shown that the initial characteristics of the Si-SiO<sub>2</sub> structures and the gas used are critical for the plasma-forming of both the interface and inversion channel properties. (Author abstract) 20 refs.

Kassabov, J. (Bulgarian Acad of Sciences, Sofia, Bulg); Atanasova, E.; Dimitrov, D.; Goranova, E. *Microelectron J* v 18 n 5 Sep-Oct 1987 p 5-12.

**096238 ELECTRONIC PROPERTIES OF A PHOTOCHEMICAL OXIDE-GaAs INTERFACE.** The properties of a GaAs-oxide interface formed by recently proposed photochemical oxidation in water were studied. Remarkable photoluminescence intensity enhancement was observed after oxidation which previously was interpreted as 'unpinning' of the Fermi level. However, the surface current transport and capacitance-voltage measurements consistently indicated a strong Fermi level pinning with an increased surface depletion. These apparently contradictory results can be explained by a new model in which photochemical oxidation does not unpin, but shifts the pinning position of the Fermi level towards the valence band edge. (Author abstract) 17 refs.

**096239 ELECTRICAL SWITCHING AND NOISE SPECTRUM OF Si-SiO<sub>2</sub> INTERFACE DEFECTS GENERATED BY HOT ELECTRONS.** We observe at low temperatures the noise caused by switching the occupancy of individual interface defect states that have been created during electrical stress with high drain voltages. These results are compared with measurements of traps present in undamaged n-channel Si(100) MOSFETs. (Author abstract) 6 refs.

Bollu, M. (Technische Univ Muenchen, Garching, West Ger); Koch, F.; Madenach, A.; Scholz, J. *Appl Surf Sci* (1985) v 30 n 1-4 Oct II 1987, INFOS 87: Proc of the Fifth Int Conf on Insul Films on Semicond, Louvain, Belg, Apr 13-15 1987 p 142-147.

**096240 INDIVIDUAL INTERFACE STATES AND THEIR IMPLICATIONS FOR LOW-FREQUENCY NOISE IN MOSFETs.** We show that the wide distribution of time constants required to explain 1/f noise in MOSFETs arises as a natural consequence of the multi-phonon model of carrier trapping into individual Si-SiO<sub>2</sub> interface states. A new class of random telegraph signal found in the drain current of small-area silicon MOSFETs is described. These signals are a result of defect metastability and are shown to be a source of non-Gaussian noise. (Author abstract) 15 refs.

**096241 IMPROVEMENT OF THE Si-SiO<sub>2</sub> INTERFACE STRESS RESISTANCE OF THIN GATE OXIDES AFTER CHANNEL ION IMPLANTATION.** The effect of phosphorus and boron ion implantation into silicon dioxide films is examined with regard to the resistance of the Si-SiO<sub>2</sub> interface under high field constant current stress conditions. Phosphorus and boron ions of various doses and energies have been implanted through a approx. 35 nm thick oxide. The interface stress resistance is found to decrease with increasing ion dose and increase with implant energy. However, at high energies, the stress resistance of the boron implanted samples is significantly less than the phosphorus equivalents due to the creation of a second interface trap level. Post-implant annealing increases the interface stress resistance but the best performance is observed for the case of sacrificial oxidation. (Author abstract) 6 refs.

**096242 SOME MATERIAL STRUCTURAL PROPERTIES OF SOI SUBSTRATES PRODUCED BY SDB TECHNOLOGY.** SOI substrates have been produced by silicon direct bonding (SDB) technology. Thermal oxides ranging in thickness from native oxide to anjnm or even more, on either or both wafers have been bonded successfully. The fracture strength of the SOI layer is 130-200 kg/cm<sup>2</sup> which is similar to the value of intrinsic bulk silicon. Dislocations have been shown to be concentrated on the backsides of the substrate and no additional defects have been developed within 80 μm of the Si-SiO<sub>2</sub> bonding area. Mobility and minority carrier lifetime similar to that of the original bulk silicon have been obtained after annealing. (Author abstract) 3 refs.

## Semiconductor Metal Boundaries

**096243 DETERMINATION OF Si-SiO<sub>2</sub> INTERFACE TRAP PROPERTIES OF p-MOS STRUCTURES WITH VERY THIN OXIDES BY CONDUCTANCE MEASUREMENT.** The interface traps of as-oxidized p-MOS structures with very thin (88-434 Å) oxides are characterized by conductance technique. The interface trap density is found to increase inversely with the oxide thickness. The hole capture cross sections  $\sigma_p$  show no obvious dependence on the oxide thickness, but decrease exponentially with energy towards the midgap. The dispersion parameters  $\sigma_s$  are compared with the theoretical predictions based on the patchwork model. Both the magnitude and bias dependence of the measured  $\sigma_s$  are much larger than the theory predicts. With numerical simulation, it is shown that the width of the conductance peak can be strongly influenced by the behavior of the capture cross section. By incorporating the energy dependence of  $\sigma_p$  into the patchwork model, good agreement between the experimental values and theoretical estimations of  $\sigma_s$  is obtained. (Author abstract) 5 refs.

## Spectroscopic Analysis

**096245 GATE CHARGE RELAXATION MECHANISM OF MOS STRUCTURE WITH ZERO BIASED SOURCE AND TRANSIENT SPECTROSCOPIC MEASUREMENT OF Si/SiO<sub>2</sub> INTERFACE STATE DISTRIBUTION NEAR MINORITY CARRIER BAND EDGE.** The gate charge relaxation mechanism of MOS structure with zero biased source region is investi-

gated under a small gate square pulse. It is demonstrated that when the Fermi level goes to the surface minority carrier energy band edge, this mechanism will turn from carrier capturing and emitting of interface states to minority carrier diffusing and drifting delayed by interface state trapping. The theoretically predicted behaviors of such a minority carrier transportation are verified by experiments. Based on this theory a new measurement principle for Si/SiO<sub>2</sub> interface state density near minority carrier band edge is proposed and the  $D_{it}(E)$  formula is deduced. The  $D_{it}(E)$  distributions show some important and common features. Even in the energy position 0.05 eV, apart from the minority carrier edge, reasonable  $D_{it}(E)$  measurement is also obtainable by this method. (Author abstract) 8 refs. In Chinese.

**096246 SPECTROSCOPY OF ONE-DIMENSIONAL SUBBANDS ON InSb.** By means of high-resolution optical lithography two-dimensional (2D) electron inversion layers in metal-oxide-semiconductor (MOS) structures on InSb are laterally confined to narrow channels. The widths of the channels ( $w \approx 100$  nm) are comparable to the de-Broglie wavelength of the electrons and formation of one-dimensional (1D) subbands results. This is verified by direct spectroscopy of intersubband transitions between the 1D subbands at far-infrared frequencies. Cyclotron resonance experiments also show the importance of the lateral confining potential. In particular, the transition from 1D to 2D electronic behavior is observed when the magnetic field strength is increased and the cyclotron radius  $l$  becomes much less than the channel width  $w$ . ## Substrates

**096248 CHARACTERISTICS OF CMOS DEVICES IN HIGH-ENERGY BORON-IMPLANTED SUBSTRATES.** CMOS devices on substrates subject to high-energy implantation of boron for buried-layer fabrication are examined. FET device characteristics, threshold voltage, and breakdown characteristics are investigated, along with mobility and minority-carrier lifetime. In addition, well leakage and breakdown are studied in an effort to provide guidelines for well design in a megaelectronvolt-implanted substrate. It is seen that MOSFET transistor characteristics are virtually unaffected by the implant. Latchup behavior improves with the incorporation of the buried layer, and the holding voltage increases as the well and implant depths decrease. 12 refs.

## Surface Properties

**096249 INVESTIGATION OF INTERFACE PECULIARITIES IN ANODIZED p-InSb MOS STRUCTURES.**

**TURES.** C-U measurements are made on p-InSb MOS structures in an extended frequency range (2 Hz to 50 kHz) at temperatures of 4.2 and 77 K. The effect of illumination with different intensities and also of stationary magnetic fields up to 5 T on the C-U characteristic are analyzed. The surface photoelectric electromotive force and its dependence of the illumination intensity are measured. The density of the localized surface states ( $10^{12} \text{ eV}^{-1} \text{ cm}^{-2}$ ) and a state density peak ( $10^{13} \text{ eV}^{-1} \text{ cm}^{-2}$ ) near the conduction band edge are determined from the measured dependences. The effect of magnetic field on the C-U characteristic without illumination is explained qualitatively and quantitatively. The results of the surface photoelectric emf measurements are analyzed qualitatively yielding to a special barrier mechanism for its formation. (Author abstract). 15 Refs.

## Temperature Effect

**096250 CRYOGENIC TEMPERATURE DEPENDENCE OF THE VOLTAGE TRANSFER CHARACTERISTICS OF CMOS INVERTERS.** The voltage transfer characteristics of CMOS inverters have been studied as a function of temperature between 77 and 300 K and supply voltages between 2 and 20 v. The logic levels, maximum gain, unity gain points, noise margins and other parameters, such as ( $V_H - V_L$ ), all showed improvement as the temperature was lowered. For one inverter with a supply of 5 v, the maximum gain increased from 57 to 105, ( $V_{IH} - V_{IL}$ ) decreased from 0.50 to 0.28 v and ( $V_H - V_L$ ) increased from 4.46 to 4.75 v on decreasing the temperature from 300 to 77 K. For all inverters, these and other parameters showed a smooth monotonic improvement as the temperature was lowered. These and other results obtained can be qualitatively explained as due to an increase in the absolute values in the threshold voltages of the PMOS and NMOS transistors and to an increase in the carrier mobility as the temperature was lowered. (Edited author abstract). 31 refs.

**Testing** See Also DATA STORAGE, DIGITAL—Random Access; INTEGRATED CIRCUIT TESTING; INTEGRATED CIRCUIT TESTING—Failure.

**096251 CMOS MOBILITY DEGRADATION COEFFICIENTS AT LOW TEMPERATURES.** An AC measurement technique is applied to NMOS and PMOS devices fabricated using a 1.25  $\mu\text{m}$  CMOS process. The parasitic resistance and mobility degradation coefficients have been extracted for temperatures between 25 K and 300 K. The NMOS parasitic resistance stays flat with temperature while the PMOS resistance rises sharply below 200 K, probably due to the light source/drain diffusion doping. The mobility reduction parameter  $\theta$ , shows a clear 1/T behavior between 100 K and room temperature, with  $\theta$  approaching unity for the PMOS devices. This may have serious implications for the performance of highly scaled devices which operate at high transverse electrical fields. (Author abstract) 12 refs.

**096252 UNIVERSAL TEST SET FOR CMOS CIRCUITS.** A universal test set for CMOS circuits is demonstrated that can be derived from the functional description of the circuit alone. It is shown that for a restricted class of CMOS circuits, the gate-level universal test set (UTS<sub>g</sub>) consisting of maximal false vectors and minimal true vectors can sensitize every detectable stuck-open fault in the circuit. A universal initialization set (UIS) is defined which can also be derived from just

the functional description, and which contains initialization vectors for each of the test vectors. This set consists of maximal true vectors and minimal false vectors. It is shown that a test set on UTS<sub>g</sub> and UIS can be guaranteed to detect every detectable stuck-open fault in both redundant and irredundant CMOS implementation of the function, even in the presence of arbitrary delays and timing-skews. The size of the test set is also investigated. 14 refs.

## Theory

**096253 NEW CAPABILITIES OF THE CMOS INVERTER.** Capabilities of the CMOS inverter are introduced that are based on the theory that for  $V_{Tn} = |V_{Tp}| \approx 2/3V_{SS}$ , a third high-impedance (HI) valid logic state is created between the zero and one states. By the generation of a 'HALF' level ( $= 1/2V_{SS}$ ), the inverter can be used as a tristate inverter. Circuit techniques to propagate the HALF level are given. This enables the general design of tertiary logic circuits and possibly tertiary arithmetic circuits. Two application examples are given. Illustrative experiments based on commercial ICs have been carried out, and results that verify the theory are given. This should open the way for digital circuits and applications. Improvements on the HALF propagation are needed which, in addition to the circuit level, may be thought of on the process and/or the device levels. 4 refs.

## Thermal Properties

**096254 TEMPERATURE DEPENDENCE OF THE MOS MOBILITY DEGRADATION.** The mobility of carriers in a MOS inversion layer appears to decrease as the degree of inversion increases. An investigation using Kelvin contact specimens has separated the extrinsic effect caused by the parasitic contact resistances to the channel and the intrinsic, surface scattering effect. The temperature dependence of the intrinsic effect is reported. The intrinsic effect appears to be process-dependent. (Author abstract). 5 Refs.

## Transport Properties

**096255 NEW METHOD FOR THE SIMULTANEOUS DETERMINATION OF THE SURFACE-CARRIER MOBILITY AND THE METAL-SEMICONDUCTOR WORK-FUNCTION DIFFERENCE IN MOS TRANSISTORS.** The method consists of simple measurements of the drain conductance in the linear region of output characteristics for a series of MOS transistors with gate oxides of different thicknesses. Provided the effective mobility does not depend on oxide thickness, both the mobility and the work-function difference can be determined without the need of determining the threshold voltage. The reduced work-function difference  $\phi^*_{MS}$  can be determined even if substrate impurity concentration is unknown. A practical verification of the method is done by reanalysis of experimental data in the literature. 11 refs.

## Tunneling

**096256 MODIFICATION TO THE FOWLER-NORDHEIM TUNNELING CURRENT CALCULATION FOR THIN MOS STRUCTURES.** This paper presents a new computer modeling of Fowler-Nordheim (F-N) tunneling current from an inverted silicon surface to the metal gate of the thin oxide MOS structures. In this model the tunneling current through the oxide is taken to be proportional to the product of the gate oxide field and the inversion layer carrier concentration. Within the semiconductor the standard semiconductor equations are solved to ensure electron current at the semiconductor surface is equal to the tunneling current through the oxide. The computational results indicate that the current-voltage characteristics of the structure would saturate if it is limited by carrier generation in the space-charge region of the silicon. (Edited author abstract) 9 refs.

Oh, Seog-Ju (Univ of Queensland, St. Lucia, Aust); Yeow, Y.T. *Solid State Electron* v 31 n 6 Jun 1988 p 1113-1118.

**096257 TUNNELING LEAKAGE IN GE-PREAMORPHIZED SHALLOW JUNCTIONS.** CMOS shallow junctions with depths less than 0.2  $\mu\text{m}$  were fabricated using Ge-preamorphization and rapid thermal annealing. A low bulk generation current ( $< 1 \text{ nA/cm}^2$ ) for both poly-gated and Al-gated diodes was obtained by placing the extended end-of-range defects inside the heavily doped junction. However, gated diode characterization shows a large tunneling current component in addition to the bulk generation current when the surface is accumulated by the gate. By comparing preamorphized with nonpreamorphized junctions for both poly-gated and Al-gated diodes, it is concluded that the tunneling effect is due to the presence of the midgap states within or near the depletion region at the surface of the junction edge. These midgap states are a result of the crystal damage associated with Ge preamorphization. PISCES simulations of this tunneling current show good agreement with the experimental results, which show that gate-induced drain leakage in N<sup>+</sup> poly-gate PMOS devices at high drain voltages is strongly dependent on removal of junction implantation damage. 24 refs.

**096258 SELF-CONSISTENT MONTE CARLO SIMULATION FOR TWO-DIMENSIONAL ELECTRON TRANSPORT IN MOS INVERSION LAYER.** Hot electron transport in a MOS inversion layer on a (100) silicon surface was analyzed by using a rigorous Monte Carlo method while taking into account changes in subband structures due to electron repopulation. An iterative procedure of the method consisted of a self-consistent calculation of the Schroedinger and Poisson's equations as well as a Monte Carlo calculation for electron scattering. The calculated relative electron population in each subband significantly differed from the results of a conventional Monte Carlo calculation in a tangential electric field higher than 10 kV/cm, above which carrier heating effects greatly influence the subband structures.

The calculated electron drift velocity is in reasonable agreement with the experimental data. (Author abstract) 16 refs.

**096259 THIS SMART POWER CHIP BREAKS THE 100-V BARRIER.** Smart power MOSFET devices were sought that can be rated at more than 400 volts. By putting low-power control logic and a high-voltage power device on a single chip, much of the processing that would otherwise have to be done by an external microprocessor is offloaded onto the chip. Thus the sensitive control circuitry is isolated from the high voltages in the power circuit. A first silicon chip that can operate at 500 volts is introduced, with the logic circuitry implemented in CMOS.

Anon. *Electronics* v 59 n 32 Oct 2 1986 p 89-91.

**096260 COMPARISON OF MINIMUM PROPAGATION DELAY AND UNITY POWER TRANSFER FREQUENCY OF SUBMICRON MOSFETS.** The object of this communication is to demonstrate a relationship between the maximum small-signal frequency of operation and the large-signal propagation delay of a submicron MOSFET. A figure of merit for the MOSFET is derived as the frequency for which the ratio of power transferred between stages of identical amplifiers equals unity. This frequency (unity power transfer frequency) is determined for submicron MOSFETs with resistive loads and is compared with the propagation delay of a ring oscillator comprising identical devices. 6 refs.

Simmons, J.G. (AT&T Bell Lab, Murray Hill, NJ, USA); Taylor, G.W. *Solid State Electron* v 31 n 2 Feb 1988 p 314-316.

**096261 OUTPUT CHARACTERISTIC STABILIZATION OF POWER MOSFETS.** The saturation current of a biased MOS transistor decreases as the temperature is raised. Thus self-heating results in a negative equilibrium output conductance and the possibility of instability in the circuit. Experiments are reported to show that this effect can be relieved over a wide range of bias conditions using a controlled substrate bias driven from an integrated MOS sensor. (Author abstract). 3 Refs.

**096262 PUNCHTHROUGH CURRENT FOR SUBMICROMETER MOSFETS IN CMOS VLSI.** Simulated and measured data show that drain-induced barrier lowering (DIBL) in buried-channel MOSFETs is different from that in surface channel (SC) MOSFETs. This is explained by the differences between channel current paths and channel potential distribution. A new parameter, defined as the incremental voltage that the drain can sustain before the punchthrough current increases by an order of magnitude, is used to indicate the rate of increase of punchthrough current and is a measure of DIBL. 9 refs.

**096267 SIMPLE EXPLICIT EXPRESSIONS FOR THE MODERATE INVERSION LIMITS IN LONG CHANNEL MOSFETS FOR ANALOG APPLICATIONS.** For the long-channel MOSFET, which is extensively employed in analog integrated circuits, explicit expressions are proposed for the weak/moderate inversion and moderate/strong inversion limit points. Empirical expressions are suggested that describe the variation of these limits with temperature for a variety of process parameters and bias conditions. A way of modeling the drain current in the moderate inversion region is suggested. 7 refs.

Bagheri, Mehran (Bell Communications Research Inc, Red Bank, NJ, USA). *Solid State Electron* v 30 n 12 Dec 1987 p 1357-1359.

**096268 THRESHOLD VOLTAGE OF SHORT-CHANNEL BC-MOSFET IN THE ENHANCEMENT MODE.** The buried-channel MOSFET (BC-MOSFET) has received considerable interest because the carrier mobility in a buried channel is higher than the surface mobility. A BC-MOSFET normally operates in the depletion mode, i.e. a remaining channel exists in the bulk after the top and bottom of the implant region are depleted by the gate voltage and the substrate-channel junction. The threshold voltage of a short-channel BC-MOSFET in the depletion mode has been studied in the past. However in devices where the channel-implant concentrations are low or the reverse bias at the substrate is high enough, the depletion region due to the sub-

strate-channel junction can reach the semiconductor surface, and conduction is due to the accumulation of majority carriers at the surface induced by the gate electric field. This is defined as the enhancement mode. We derive the threshold voltage of a short-channel BC-MOSFET considering both the depletion and enhancement modes. 7 refs.

Tong, K.Y. (Hong Kong Polytechnic, Hung Hom, Hong Kong). *Solid State Electron* v 30 n 12 Dec 1987 p 1359-1361.

**096269 HOT-CARRIER ANALYSIS OF SUBMICROMETER MOSFETS.** Based on Monte Carlo (MC) device simulations, an analysis of hot-carrier effects in submicrometer n-MOSFETs is presented that provides detailed insight because the high-energy electrons are treated directly. The dc stress characteristics of both lightly-doped drain (LDD) and conventional As source/-drain devices are found to correlate with the surface hot-electron concentration, and agreement with experimental data shows that the electron flux above 3 eV, integrated along the channel, can be used to predict device degradation. The simulations indicate that the whole dc stress characteristic can be attributed to hot electrons, while the holes generated by impact ionization have a very small probability of gaining enough energy to be injected over the oxide barrier. 15 refs.

**096270 THREE-DIMENSIONAL ANALYSIS OF SUBTHRESHOLD SWING AND TRANSCONDUCTANCE FOR FULLY-RECESSED-OXIDE (TRENCH) ISOLATED 1/4-μm-WIDTH MOSFETS.** The dependence of MOSFET gate controllability on the field-isolation scheme is investigated using three-dimensional simulation. It is found that a fully-recessed-oxide (trench) isolated MOSFET has a steep subthreshold characteristic and high transconductance in comparison with a non-recessed device. These features result from the small depletion capacitance due to the crowding of the gate's fringing field at the channel edge. It is also found that the gate and diffused line capacitances in the case of fully-recessed-oxide isolation are small, so that high-switching-speed operation can be expected. These features are enhanced with a reduction in the channel width, especially for lower-submicrometer-width MOSFETs. A drawback of a fully-recessed-oxide MOSFETs is its low threshold voltage. However, the leakage current is not as large as that inferred from the inverse narrow-channel effect because of its steep subthreshold characteristic. Several countermeasures for this low threshold voltage are discussed. 17 refs.

**096271 SEMI-ANALYTICAL APPROACH TO THE EVALUATION OF THRESHOLD VOLTAGE IN DEPLETION MOS'S WITH NONUNIFORMLY DOPED SUBSTRATES.** D.A. Antoniadis' algorithm (1984) is extended to cover the computation of threshold voltage for depletion or buried-channel MOSFETs. It is shown that a key factor in its evaluation, of the derivative of the integral charge of the mobile minority carriers in the substrate with respect to the gate-source bias, can easily be calculated using the concept of flat-band capacitance. The threshold voltage is thus computed without requiring strict numerical solution of Poisson's equation, yet the accuracy is very good. This modified algorithm has been

implemented in SUPREM III, and good agreement between simulation and experimental results has been achieved. 5 refs.

**096272 TWO-DIMENSIONAL NUMERICAL ANALYSIS OF THE FLOATING REGION IN SOI MOSFETS.** Results of simulating SOI/MOSFET (silicon-on-insulator/ metal-oxide-semiconductor field-effect-transistor) devices using the full two-dimensional numerical solution of the classical semiconductor equations are presented. Particular attention has been paid to the role of the floating region, and it is demonstrated that removal of this phenomenon is important for the improvement of the performance of SOI/MOSFET devices. Several methods, such as applying a back gate bias or using thinner (100-nm) films, are investigated as a means of controlling this undesirable feature. It is shown that the use of thin films has major advantages. It is concluded from a study of the effect of lifetime on device performance that improved film quality can have an adverse effect on the  $I_d-V_d$  characteristics, giving an enhanced kink and earlier breakdown on 0.3- $\mu$ m silicon films. 11 refs.

**096273 INFLUENCE OF THE EPITAXIAL LAYER ON THE CURRENT-VOLTAGE CHARACTERISTICS IN HIGH VOLTAGE VDMOS DEVICES. ANALYSIS OF THE QUASI-SATURATION POINT.** In this paper, the influence of the epitaxial layer on the current-voltage characteristics,  $I_D(V_D)$ , for high voltage VDMOS (vertical double-diffused MOS transistor devices) is analyzed. The quasi-saturation point of the  $I_D(V_D)$  curve and its evolution with the drain bias are studied. The epitaxial layer resistance is considered in the saturation and quasi-saturation operation modes. (Author abstract) 8 refs.

## Automatic Testing

**096274 CURVE TRACERS ADVANCE MOSFET TECHNOLOGY.** In a typical curve tracer application, the device-under-test (DUT) can range from a two-, three-, or four-terminal device (i.e., diodes, transistors, and thyristors) to multipin optoelectronic devices and ICs. Rather than testing singlepoint parameters, the curve tracer shows what actually happens in a device over its full range of operation. By exercising each pin of the device, the curve tracer can provide a family of output curves representing the dc (static) parameters that characterize the entire operational range of the DUT. This makes curve tracers ideal for checking the success of a particular stage of processing, or for characterizing the device after it has been completed. It is reported how the curve tracer has accelerated development of a revolutionary MOSFET power device.

## Calculations

**096275 MODELLING DC CHARACTERISTICS OF MOSFET.** An empirical formula is presented for the current-voltage characteristics of the metal oxide semiconductor field effect transistor (MOSFET). The three parameters of the formula can be calculated easily from separate regions in the device dc characteristics without recourse to special electrical measurements or global curve-fitting

techniques. By using this formula, the implementation of a new MOSFET model into the source code of Spice is feasible. (Author abstract) 17 refs.

## Charge Carriers

**096276 STRESS-BIAS DEPENDENCE OF HOT-CARRIER-INDUCED DEGRADATION IN MOSFETS.** The stress-bias dependence of hot-carrier-induced degradation in short N-channel MOSFETs is examined. A positive stress electric field ( $V_{gs} > V_{ds}$ ) across the gate oxide results in a characteristic  $g_m$  shift to the positive  $V_{gs}$  direction and a large  $V_t$  degradation with a low rate of shift. In contrast, a negative stress field ( $V_{gs} < V_{ds}$ ) causes a reduction in magnitude in  $g_m$  with a negligible peak shift and a small initial  $V_t$  degradation with a fast shift rate. The effect of stress-bias on the turn-on characteristics has also been investigated. It is proposed that the degradation observed in the case of positive electric-field stress is essentially due to the localized electron trapping in the oxide near the drain, whereas the case of negative E-field stress is mainly due to interface-trap generation localized near the drain. (Author abstract) 11 refs.

## Computer Simulation

**096280 AUTOMATIC EXTRACTION SYSTEM FOR MOSFET MODEL PARAMETERS IN CIRCUIT SIMULATION.** The MOSFET model of SPICE2 circuit simulator is studied. This model requires about thirty parameters, and the accuracy of the simulation

depends on these parameters. Therefore, in order to make a MOSFET model available, these parameters must be precisely and efficiently extracted. For this reason, a simple and useful computer-controlled extraction system for MOSFET model parameters has been developed. This system measures I-V characteristics required for parameter extraction automatically and calculates each parameter with small error. The validity of the extracted parameters produced by this system was verified by comparing simulated MOSFET characteristics with the measured ones. Good agreement has been obtained, and the system has been proved very useful and practical. This paper describes the system and discusses the extraction method used. 4 refs.

**096281 CMOS DEVICE MODEL FOR ACCURATE CIRCUIT SIMULATION APPLICATION.** This paper proposes a submicron CMOS device model which is used in the charge oriented circuit simulation to achieve higher-accuracy circuit analysis. The features of this model are: (1) continuity of drain conductance at the pinch-off voltage ensures accurate expression of the drain conductance which is especially important in designing analog circuits; (2) minority carriers in the pinch-off region are considered to express accurately the current and capacitance characteristics in the saturation region. (Edited author abstract) 16 refs.

**096282 MODIFIED SPICE II MODELS MODERN POWER MOSFETS.** The SPICE II simulation software package is a widely available, well understood design tool for i.c. modeling and analysis; however, it has its limitations. Since SPICE II's internal device models can't be easily changed for all existing copies, the authors updated the capabilities of this simulation package by adding a 'subcircuit' of external components that complement the devices within the SPICE II software, so as to form a true, equivalent circuit of a power MOSFET. The subcircuit works with the standard SPICE II software, providing a model with all the terminal characteristics of a power MOSFET. Parameters of the subcircuit model can be determined from simple terminal measurements or from standard data sheets, using the algorithm and empirical approach described in the article. 3 refs.

## Defects

**096284 TWO-DIMENSIONAL MODELING AND PARAMETER EXTRACTION OF AGED MOSFETS.** The effect of stress induced defects on the ohmic region characteristics of short channel MOSFETs is analyzed by means of a two dimensional device simulator. The device aging is summarized in the formation of a narrow defective interface region whose nature, length and position above the channel are the parameters of our investigation. The channel conductance and transconductance degradations were found to be greatly influenced by the position of the defective region and its length. Also, fundamental differences were observed between the effects of interface states and fixed oxide charges. The interaction between the

defective and defect-free channel regions was found to produce a transconductance overshoot which attenuates the aging effects. Finally, a parameter extraction method based on a two-piece analytical model of locally damaged MOSFETs is elaborated and validated by means of a 2-D simulation. (Author abstract) 8 refs.

## Degradation

**096285 DEGRADATION OF SUBMICRON MOSFETs AFTER AGING.** The degradation was investigated after electrical stress. New methods for the aging investigation based on field effect mobility measurements are presented. The correlations between the different degradation parameters are analysed by one-dimensional modelling that takes into account the potential fluctuations induced by the surface state and charge generation. The degradations increase with the bias parameter  $K = U_g/U_d$  applied during stress. In addition, the partial reversibility of degradations shows that electron trapping is the main cause of aging. (Edited author abstract) 21 Refs.

Cabon, B. (CNRS, Grenoble, Fr); Ghibaudo, G. *Phys Status Solidi A* v 107 n 1 May 1988 p 393-404.

**096286 HOT-ELECTRON EFFECTS IN SILICON-ON-INSULATOR N-CHANNEL MOSFETs.** Hot-electron degradation has been measured in short-channel bulk and SOI MOSFETs. The presence of a floating substrate in the SOI devices appears to increase the drain-saturation voltage and therefore to reduce the drain electric field. This effect is further enhanced when thin fully depleted films are considered. Electrical stress measurements and device modeling suggest that hot-electron degradation will be smaller in SOI MOSFETs than in their bulk counterparts. 8 refs.

Coline, Jean-Pierre (Hewlett-Packard Lab, Palo Alto, CA, USA). *IEEE Trans Electron Devices* v ED-34 n 10 Oct 1987 p 2173-2177.

**096287 TRAPPED-ELECTRON AND GENERATED INTERFACE-TRAP EFFECTS IN HOT-ELECTRON-INDUCED MOSFET DEGRADATION.** An experimental method is proposed to distinguish the electron-trapping effect in the gate oxide from the interface-trap generation effect in hot-electron-induced MOSFET degradation. In this method, by selecting the appropriate bias conditions, hot electrons and/or hot holes are intentionally injected into the oxide region above the channel outside the drain layer, which affects MOSFET characteristics such as threshold voltage and transconductance. The negative charges of electrons trapped in the oxide during hot-electron injection are completely compensated for by the positive charges of subsequently injected and trapped holes, and the trapped electron effect in the degradation is eliminated. Using this method, the causes for hot-electron-induced transconductance degradation ( $\Delta g_m/g_m$ ) are analyzed. As the degradation increases, the trapped-electron effect decreases, and the generated interface-trap effect increases. A relationship between  $g_m$  degradation due to generated interface-traps and  $\Delta g_m/g_m$  is established. 15 refs.

Tsuchiya, Toshiaki (NTT, Atsugi, Jpn). *IEEE Trans Electron Devices* v ED-34 n 11 Nov 1987, 45th Annu Device Res Conf, Santa Barbara, CA, USA, Jun 22-24 1987 p 2291-2296.

**096288 HOT-CARRIER-INDUCED DEGRADATION IN MOSFETs STUDIED BY RECOVERY TEMPERATURE SPECTROSCOPY (RTS).** After electrical stress, the MOSFET was quickly heated up to the first temperature of the RTS, kept for a constant time (e.g., 3 min.), and quenched. Then the device characteristics, for example, transconductance, were measured. The procedure is repeated with the temperature raised step by step by a constant value. The temperature derivative of the measured characteristics, i.e., the recovery temperature spectrum, yields information on the activation energy ( $E_a$ )

) and frequency factor ( $f$ ) of the thermal recovery reaction. The authors used an ALDD n-channel MOSFET which is essentially the same structure as the ITLDD, the LDD MOSFET free from spacer-induced degradation. Two hot-electron-related peaks and one hot-hole-related peak were identified in the recovery temperature spectra. As a result, the usefulness of the RTS in hot-carrier-induced degradation studies has been confirmed.

**096290 INTERFACE TRAP EFFECTS ON THE HOT-CARRIER INDUCED DEGRADATION OF MOSFETs DURING DYNAMIC STRESS.** Foundry and hardened n-channel MOSFETs were stressed with dynamic ac pulses and with static dc voltages. The preradiation hot-carrier induced degradation is identical for devices from both processes when subjected to static stress, but when subjected to dynamic stress, the degradation is much more severe for the hardened devices. The data suggest that the degradation is strongly influenced by the pulse structure. It is proposed that the initial density of interface traps may be responsible for the enhancement in degradation exhibited by the hardened devices following dynamic stress. 16 refs.

Suehle, J.S. (NBS, Gaithersburg, MD, USA); Russell, T.J.; Galloway, K.F. *IEEE Trans Nucl Sci* v NS-34 n 6 Dec 1987, 1987 Annu Conf on Nucl and Space Radiat Eff, Snowmass Village, CO, USA, Jul 28-31 1987 p 1359-1365.

**096291 HOT-ELECTRON DEGRADATION OF N-CHANNEL POLYSILICON MOSFETs.** The stability of the hydrogen passivation in hydrogenated n-channel polysilicon MOSFETs has been studied under thermal stress and hot-electron stress at elevated temperatures. Although the hydrogen passivation is stable at 150°C, channel hot-electron stress at high temperatures appears to create additional grain boundary traps, presumably by breaking the Si-H bonds at the grain boundaries. This mechanism is in addition to the creation of acceptor-type fast interface states that occur in bulk MOSFETs. 11 refs.

Banerjee, Sanjay (Texas Instruments Inc, Dallas, TX, USA); Sundaresan, Ravishankar; Shichijo, Hisashi; Malhi, Satwinder. *IEEE Trans Electron Devices* v 35 n 2 Feb 1988 p 152-157.

**096292 GATE OXIDE CHARGE-TO-BREAKDOWN CORRELATION TO MOSFET HOT-ELECTRON DEGRADATION.** Substrate current by itself is found not to be a sufficient indicator of degradation. Experiments using active-area test capacitors with and without poly edges confirm that the gate-oxide trap density beneath the poly edges is equally important in determining the degradation. Certain processing steps have been identified as being responsible for gate-oxide degradation. An optimization of these steps has resulted in improved hot-electron degradation behavior. 11 refs.

Davis, Marshall (Natl Semiconductor Corp, Puyallup, WA, USA); Lahri, Rajeeva. *IEEE Electron Device Lett* v 9 n 4 Apr 1988 p 183-185.

**096293 HOT-CARRIER-INDUCED DEGRADATION IN P-MOSFETs UNDER AC STRESS.** Lifetimes under AC stress are calculated with a quasistatic model using parameters extracted from DC stress data. For inverter-like waveforms, the measurement data show reasonable agreement with the simulation results. For waveforms with turnoff transient occurring in the presence of high drain voltage, more degradation than the model predicts is found if the transient is short ( $\leq 10$  ns) and gate voltage is high. 9 refs.

Ong, T.-C. (Univ of California, Berkeley, CA, USA); Seki, Kouichi; Ko, P.K.; Hu, Chenming. *IEEE Electron Device Lett* v 9 n 5 May 1988 p 211-213.

**096294 HOT-ELECTRON-INDUCED DEGRADATION OF CONVENTIONAL, MINIMUM OVERLAP, LDD AND DDD N-CHANNEL MOSFETs.** Substrate current characteristics of conventional minimum overlap, DDD (double-diffused drain), and LDD (lightly doped drain) (n-channel MOSFETs with various LDD n<sup>+</sup> doses have been studied. Threshold voltage shift, transconductance degradation, and change of substrate current for these devices after stressing were also investigated. The minimum gate/drain overlap devices had the highest substrate current and the worst hot-electron-induced degradation. The amount of gate-to-n<sup>+</sup> drain overlap in LDD devices was an important factor for hot-electron effects, especially for devices with low LDD n<sup>+</sup> doses. The injection of hot holes into gate oxide in these devices at small stressed gate voltages was observed and was clearly reflected in the change of substrate current. The device degradation of low-doped LDD n-channel MOSFETs induced by AC stress was rather severe. 18 refs.

Liou, Tian-I (Natl Semiconductor Corp, Santa Clara, CA, USA); Teng, Chih-Sieh; Merrill, Richard B. *IEEE Circuits Devices Mag* v 4 n 2 Mar 1988 p 9-15.

**096295 SIMULATION OF MOSFET LIFETIME UNDER AC HOT-ELECTRON STRESS.** A substrate current model and a quasistatic hot-electron-induced MOSFET degradation model have been implemented using the Substrate Current And Lifetime Evaluator (SCALE) package. It is shown that quasistatic simulation is valid for a class of waveforms that includes those encountered in inverter-based logic circuits. The validity and limitations of the model are illustrated with experimental results. SCALE is linked to SPICE externally in a pre- and postprocessor fashion to form an independent simulator. The preprocessor interprets the input deck and requests SPICE to output the transient node voltages of the user-selected devices. The postprocessor then calculates the transient substrate current and makes a lifetime prediction. 11 refs.

**096296 SUPPRESSION OF HOT-CARRIER EFFECTS IN SUBMICROMETER SURFACE-CHANNEL PMOSFETs.** Hot-carrier-induced degradation in surface-channel (p-type polysilicon gate) PMOSFETs is investigated. Hot-electron-induced punchthrough is found to limit the lifetime of these devices. Although these surface-channel devices are observed to be more reliable than conventional buried-channel transistors, a lightly doped drain design is found to be necessary to provide adequate suppression of hot-carrier generation in 0.8- $\mu$ m-gate-length ( $L_{eff} = 0.5 \mu$ m) transistors operated at 5 V. 7 refs.

Brassington, Michael P. (Natl Semiconductor, Palo Alto, CA, USA); Poulter, Mark W.; El-Diwan, Monir. *IEEE Trans Electron Devices* v 35 n 7 Jul 1988 p 1149-1151.

**096297 MECHANISM OF DEGRADATION OF LDD MOSFET'S DUE TO HOT-ELECTRON STRESS.** The dominant degradation mechanism in n-channel lightly doped drain (LDD) MOSFETs following hot-electron injection is identified. While there is no shift in the threshold voltage or any change in the subthreshold slope (implying no significant interface state generation), the peak value of the transconductance is found to degrade with stress time. This degradation is attributed to the increase in the source-drain series resistance, which is measured as a function of stress time. In addition, it is found that for any stress time, the measured series resistance is a strong function of the gate voltage, implying a modulation of the depletion width in the lightly doped region with change in the gate voltage. 8 refs.

## Electric Conductivity

**096300 CONDUCTANCE FLUCTUATIONS IN ULTRA-SHORT-CHANNEL SI MOSFETS.** Conductance fluctuations with gate voltage near threshold are observed at temperatures up to 10 K in metal-oxide-semiconductor field-effect transistors (MOSFETs) with wide (44  $\mu\text{m}$ ) but short ( $\leq 0.15 \mu\text{m}$ ) channels. The reproducible variations are consistent with the universal conductance fluctuations predicted by Lee and Stone. (Author abstract) 9 refs.

Chou, S.Y. (MIT, Cambridge, MA, USA); Antoniadis, D.A.; Smith, H.I.; Kastner, M.A. *Solid State Commun* v 61 n 9 Mar 1987 p 571-572.

**096301 LOCALIZED INTERFACE TRAP GENERATION IN SILO-ISOLATED MOSFET'S DURING PECVD NITRIDE PASSIVATION.** The authors report the generation of interface traps during the plasma-enhanced chemical vapor deposition of silicon nitride passivation in MOS structures that utilize a sealed-interface local oxidation scheme (SILO) for device isolation. These traps are highly localized at the boundaries between gate and field oxides, causing enhanced subthreshold conduction. Localized interface traps of this type were not observed in identical MOS structures that use conventional LOCOS (local oxidation of silicon) isolation and

were eliminated by thermal anneals at 450°C. Anneals in hydrogen ambients resulted in enhanced rates of hot-carrier-induced degradation. The high densities and localized nature of these anomalous traps make possible a novel mode of device operation in which source-drain conduction is strongly modulated by substrate bias. 12 refs.

Brassington, Michael P. (Fairchild Research Cent, Palo Alto, CA, USA); Razouk, Reda R.; Hu, Chenming. *IEEE Trans Electron Devices* v 35 n 1 Jan 1988 p 96-100.

**096302 NOVEL TRENCH-INJECTOR POWER DEVICE WITH LOW ON RESISTANCE AND HIGH SWITCHING SPEED.** A power MOSFET device structure that has been developed to optimize the tradeoff between ON resistance and switching speed is discussed. The device structure features a trench injector that injects a controlled quantity of minority carriers into the drift path of the MOSFET current to modulate the conductivity of the device during the ON state. This conductivity-modulated MOSFET device (CMDMOS) has been fabricated and characterized. The device structure has demonstrated low ON resistance and high switching speed. It can be implemented along with logic circuitry to allow programmable electrical control of the switching-speed/ON-resistance tradeoff. 7 refs.

## Electric Properties

**096303 SUBTHRESHOLD TRANSCONDUCTANCE IN THE LONG-CHANNEL MOSFET.** The transconductance-current ratio of the long-channel MOSFET approaches the ideal value of  $q/kT$  under subthreshold conditions. This behavior has previously been explained using a BJT-like model. It is shown that such a model is inappropriate, and that this phenomenon can be explained by the diffusive nature of the subthreshold current, the law governing the density gradient, and the existence of a quasi high-low junction between the source region and channel. A general expression for subthreshold transconductance is developed. It is also demonstrated analytically that the bulk and inversion-layer capacitances that enter into this expression are equal at the threshold of strong inversion, a demonstration that avoids approximations employed in a previous treatment of the matter. (Author abstract) 23 refs.

Schrimpf, R.D. (Univ of Minnesota, Minneapolis, MN, USA); Ju, D.-H.; Warner, R.M. Jr. *Solid State Electron* v 30 n 10 Oct 1987 p 1043-1048.

**096304 INFLUENCE OF HOT-ELECTRON-INDUCED AGING ON THE DYNAMIC CONDUCTANCE OF SHORT-CHANNEL MOSFETS.** An analysis of the dynamic conductance of a nonuniform MOSFET operating in weak inversion is presented. A new method for the determination of the interface state density accounting for nonuniformity and of DIBL effects is proposed. This method is suitable for the study of hot-electron-induced aging in submicron MOS transistors. It is demonstrated that the interface state density near the drain increases drastically with stress duration whereas the interface state density near the source remains almost unchanged after aging. (Edited author abstract) 15 refs.

Ghibaudo, G. (ENSERG, Grenoble, Fr); Cabon, B. *Solid State Electron* v 30 n 10 Oct 1987 p 1049-1052.

**096305 NEW METHOD FOR THE EXTRACTION OF MOSFET PARAMETERS.** A new method for the extraction of the MOSFET parameters is presented. The method, which relies on combining drain current and transconductance transfer characteristics, enables reliable values of the threshold voltage  $V_t$ , the low field mobility  $\mu_0$  and the mobility attenuation coefficient  $\theta$  to be obtained. (Author abstract) 8 refs.

Ghibaudo, G. (Sachs & Freeman Associates Inc, Landover, MD, USA). *Electron Lett* v 24 n 9 Apr 28 1988 p 543-545.

**096306 ELECTRON ENERGY DISTRIBUTION FOR CALCULATION OF GATE LEAKAGE CURRENT IN MOSFETS.** A new equation, which does not require any fitting parameters, has been developed to predict gate leakage current density in MOSFETs. The equation is based upon a non-Maxwellian hot-electron distribution function derived from the Boltzman transport equation, and utilizes a physically calculated local electron temperature. The model predicts gate currents for a sample submicron MOSFET that are in good agreement with experiment. (Author abstract) 14 refs.

Goldsman, N. (Univ of Maryland, College Park, MD, USA); Frey, J. *Solid State Electron* v 31 n 6 Jun 1988 p 1089-1092.

**096307 MODELLING THE LOCAL DAMAGE OF SHORT-CHANNEL MOSFETS DUE TO HOT ELECTRON INJECTION USING RESULTS FROM PHOTOINJECTION MEASUREMENTS ON MOS CAPACITORS.** As dimensions of MOS transistors are reduced higher lateral and transverse electric fields lead to carrier heating in the channel of the transistor. The injection of hot carriers into the insulator of a MOS device causes a change in the electrical properties due to generation of fast surface states and generation or filling of oxide traps. To obtain the kinetics of charge building up at the Si-SiO<sub>2</sub> interface and in the bulk of the insulator after electron injection, photoinjection investigations on semitransparent MOS capacitors were carried out at a field of  $1 \times 10^6$  V/cm (injection from the semiconductor). A xenon arc lamp was used for irradiation of the samples. The change of the mid-gap voltage and the increase of the concentration of fast surface states after photoinjection were determined by applying high frequency C-U measurements. 3 refs.

**096308 CONDUCTANCE TECHNIQUE IN MOSFETS: STUDY OF INTERFACE TRAP PROPERTIES IN THE DEPLETION AND WEAK INVERSION REGIMES.** A new and accurate approach to a.c. conductance measurements on MOSFETs is presented. It is shown that the conductance technique can be used to study interface trap properties in most of the silicon band-gap by direct measurement on a single MOSFET. The equivalent circuit is analyzed and the influence of the channel length on the inversion layer response is discussed. It is shown that the channel time constant is mainly determined by the channel length. For small channel lengths  $L < 5 \mu\text{m}$  the channel time constant is generally smaller than  $10^{-8}$  s. As a result rapid response, the interface traps can easily interact with the minority carrier band in inversion. Therefore, such traps can be studied in a similar way as those interacting with the majority carrier band in depletion. (Edited author abstract) 15 refs.

**096309 ELECTRICAL CHARACTERISTICS OF MOSFET'S UTILIZING OXYGEN-ARGON SPUTTER-DEPOSITED GATE OXIDE FILMS.** A study is presented of the electrical characteristics of MOSFETs utilizing oxygen-argon. The gate-oxide films deposited at low temperature (200°C) by oxygen-argon sputtering of an SiO<sub>2</sub> target. The MOSFETs formed are confirmed to have triode characteristics. Oxygen mixing makes it possible to improve considerably the MOSFET field-effect mobility and subthreshold slope over those of argon-only sputter-deposited film to 700 cm/V-s and 170 mV/decade. These improvements are the result of a large reduction in

surface-state density. The results confirm the usefulness of oxygen-argon sputter-deposited gate-oxide films for fabrication at low temperature. 11 refs.

**096310 SUBBREAKDOWN DRAIN LEAKAGE CURRENT IN MOSFET.** Significant drain leakage current can be detected at drain voltages much lower than the breakdown voltage. This subbreakdown leakage can dominate the drain leakage current at zero  $V_G$  in thin-oxide MOSFETs. The mechanism is shown to be band-to-band tunneling in Si in the drain/gate overlap region. In order to limit the leakage current to 0.1 pA/ $\mu\text{m}$ , the oxide field in the gate-to-drain overlap region must be limited to 2.2 MV/cm, which may set another constraint for oxide thickness or power supply voltage. 5 refs.

Chen, J. (Univ of California, Berkeley, CA, USA); Chan, T.Y.; Chen, I.C.; Ko, P.K.; Hu, Chenming. *IEEE Electron Device Lett* v EDL-8 n 11 Nov 1987 p 515-517.

**096311 ANOMALOUS SUBTHRESHOLD CURRENT-VOLTAGE CHARACTERISTICS OF N-CHANNEL SOI MOSFET'S.** The abnormally high slopes of the subthreshold current-voltage characteristics exhibited by n-channel silicon-on-insulator (SOI) MOSFETs are experimentally related to defect density (off-state leakage current) as well as drain voltage and channel length, and a theoretical physical description of the measured relations is presented and supported. The anomalous subthreshold behavior is attributed analytically to the (floating) body effect due to charging (biasing) by impact ionization at the drain. 6 refs.

Fossum, Jerry G. (Univ of Florida, Gainesville, FL, USA); Sundaresan, Ravishankar; Matloubian, Mshel. *IEEE Electron Device Lett* v EDL-8 n 11 Nov 1987 p 544-546.

**096312 HIGH-QUALITY CMOS IN THIN (100 NM) SILICON ON SAPPHIRE.** Electrical characteristics of enhancement-mode n-channel and p-channel MOSFETs in 100-nm-thick silicon-on-sapphire (SOS) are reported. Channel mobilities (linear operation) of 500 and 200  $\text{cm}^2/\text{V}\cdot\text{s}$ , respectively, have been measured in double solid-phase epitaxially (DSPE) improved material. Deep trap levels associated with the Si-sapphire interface were measured in concentrations as low as  $1 \times 10^{11} \text{ cm}^{-2}$ . These results indicate that DSPE-improved SOS films thinned to 100 nm are suitable for application to high-performance down-scaled CMOS circuitry. 15 refs.

Garcia, G.A. (US Naval Ocean Systems Cent, San Diego, CA, USA); Reedy, Ronald E.; Burgener, M.L. *IEEE Electron Device Lett* v 9 n 1 Jan 1988 p 32-34.

**096313 ELECTRICAL CHARACTERISTICS OF MOSFET'S USING LOW-PRESSURE CHEMICAL-VAPOR-DEPOSITED OXIDE.** The electrical characteristics of MOSFETs and MOS capacitors utilizing thin (80-230 angstrom) low-pressure chemical-vapor-deposited (LPCVD) oxide films deposited at 12 angstrom/min are presented. MOSFETs using CVD oxides show good electrical characteristics with 70-90% of the surface mobility of conventional MOSFETs. The CVD oxides exhibit the same low leakage current and high breakdown fields as the thermal oxides, and significantly lower trapping and trap generation rates than thermally grown oxides. Interface state densities of  $\leq 3 \times 10^{10} \text{ cm}^{-2}\text{eV}^{-1}$  are obtained from CVD devices by using a short annealing in oxygen ambient following the deposition. These results indicate that these LPCVD oxide films may be promising dielectrics for MOS device application. 13 refs.

**096314 RECOVERY OF THRESHOLD VOLTAGE AFTER HOT-CARRIER STRESSING.** The recovery of threshold voltage due to high drain or gate voltage and the

effects of hot-carrier stressing on the drain breakdown voltage of MOSFETs have been studied. A high oxide field causes slow recovery through tunneling detrapping of electrons in both p- and n-MOSFETs. For n-MOSFETs the mechanism of fast recovery is low-level hole injection at high  $V_D$ . Hot-carrier stressing at high  $V_G$  causes the drain breakdown voltage to decrease (walk-in). This results in enhanced hole injection, thus increasing the rate of subsequent recovery of  $V_t$ . The breakdown voltage increases and then decreases when stressed at low gate voltages. 20 refs.

**096315 TECHNIQUE FOR THE OBSERVATION OF INTERFACE TRAP DENSITIES IN MOSFET DEVICES.** An experimental technique is described that permits the direct measurement of interface trap densities. The measurements may be carried out at fixed, controlled values of the surface potential or surface electric field. Results obtained by this technique are compared with those found by conventional methods. (Author abstract) 8 refs.

Heasell, E.L. (Univ of Waterloo, Waterloo, Ont, Can). *Semicond Sci Technol* v 3 n Jan 1988 p 35-39.

**Fabrication** See Also SEMICONDUCTING SILICON—Doping; TRANSISTORS, FIELD EFFECT—Junctions.

**096316 NOVEL SELF-ALIGNED POLYSILICON-GATE MOSFETS WITH POLYSILICON SOURCE AND DRAIN.** A novel self-aligned technique is described for self-aligning a polysilicon gate in devices with polysilicon source and drain regions. The technique is demonstrated for two types of polysilicon source and drain devices. In one type of device, the polysilicon serves as the source of dopant for diffused source and drain junctions. In the second type, the polysilicon, together with an underlying interfacial oxide, forms a tunneling CIS (conductor-thin-insulator-semiconductor) structure. The characteristics of devices of both types fabricated under almost identical conditions using the new self-alignment technique are compared. (Author abstract) 11 refs.

**096317 SILICON-ON-INSULATOR MOS DEVICES FOR INTEGRATED CIRCUIT APPLICATIONS.** Several techniques for fabricating regions of crystalline silicon on insulating (SOI) substrates are available. These methods are described briefly and device design considerations introduced by the use of SOI are discussed. The advantages of SOI devices are described; these are absence of latch-up, process simplicity, radiation resistance, and reduction of parasitic capacitance. The physics of an SOI MOS transistor are presented. 7 refs.

Coline, Jean-Pierre. *Hewlett Packard J* v 39 n 1 Feb 1988 p 87-93.

**096318 SELF-ALIGNED UMOSFET'S WITH A SPECIFIC ON-RESISTANCE OF  $1 \text{ m}\Omega \times \text{cm}^2$ .** An improved UMOSFET with an ultralow specific on-resistance is described. This device utilizes a self-aligned process that permits closely spaced vertical trench gates with a unit cell of 6  $\mu\text{m}$ . This allows for a large increase of channel density and, therefore, reduces the on-resistance per unit area significantly. Experimental devices have been fabricated, and a specific on-resistance of  $1.0 \text{ m}\Omega \text{ cm}^2$  with a breakdown voltage of 30 V has been achieved. This specific on-resistance is the lowest value ever reported for FETs. 10 refs.

USA, Jun 22-24 1987 p 2329-2334.

**096319 FABRICATION OF THIN GATE OXIDE MOSFET'S USING LOW-TEMPERATURE PLASMA-ENHANCED CHEMICAL-VAPOR-DEPOSITED  $\text{SiO}_2$ .** The fabrication and device performance of large-area ( $9.7 \times 10^{-4} \text{ cm}^2$ ), thin-gate-oxide ( $t_{ox} \leq 200 \text{ angstrom}$ ) n-channel MOSFETs using this PECVD (plasma-enhanced chemical vapor deposition) gate oxide process are discussed. Measurements made on these MOSFETs show that they compare well to equivalently prepared thermally oxidized devices. For example, the transconductance of a 100-angstrom PECVD MOSFET was  $215 \times 10^{-9} \text{ S}$ , compared to  $275 \times 10^{-9} \text{ S}$  for a 100-angstrom thermally oxidized sample. The field effect mobilities were 352 and 460  $\text{cm}^2/\text{V}\cdot\text{s}$ , respectively; thresholds were 0.04 V for the PECVD device and  $-0.08 \text{ V}$  for the thermal device. These results were obtained from devices which received only a  $400^\circ\text{C}$  (postmetal) anneal after gate oxide deposition. This demonstrates that PECVD can be a viable candidate for reducing the number of high-temperature steps in VLSI processing. 2 refs.

**096320 FLOATING-GATE CURRENT SENSOR.** The theory and experimental results for a concept for sensing wideband currents by utilizing a MOS floating-gate device structure are described. The experimental device structure consists of a dual-gate n-channel MOSFET with the gate next to the source controlling the current injection into the channel and the gate next to the drain acting as the floating gate. The sensing of the current results from the capacitive coupling of mobile carriers in the channel to the input gate of an on-chip MOS electrometer amplifier as they pass beneath the floating gate. A difference between the floating gate current sensing concept and the more conventional resistor sensing approach is that the floating-gate current sensor is ac coupled so that dc components of the current are filtered out. Also, the floating gate current sensor has a current-to-voltage transfer function with a linear characteristic at low signal currents and a square-root characteristic at high signal currents. In addition, the floating gate frequency response is determined by the carrier transport time in the region beneath the floating gate rather than an RC time constant, as in the resistor sensing approach. The latter feature allows long current integration times without the use of high-value resistors.

Kub, F.J. (Westinghouse Electric Corp, Baltimore, MD, USA); Lin, H.C. *IEEE Trans Electron Devices* v ED-34 n 11 Nov 1987, 45th Annu Device Res Conf, Santa Barbara, CA, USA, Jun 22-24 1987 p 2383.

**096321 DEEP-SUBMICROMETER MOS DEVICE FABRICATION USING A PHOTORESIST-ASHING TECHNIQUE.** A photoresist-ashing process has been developed which, when used in conjunction with conventional g-line optical lithography, permits the controlled definition of deep-submicrometer features. The ultrafine lines were obtained by calibrated ashing of the lithographically defined features in oxygen plasma. The technique has been successfully used to fabricate MOSFETs with effective channel length as small as  $0.15 \mu\text{m}$  that show excellent characteristics. An NMOS ring oscillator with  $0.2\text{-}\mu\text{m}$  devices has been fabricated with a room-temperature propagation delay of 22 ps/stage. Studies indicate that the thinning is both reproducible and uniform so that it should be usable in circuit as well as device fabrication. Since most polymer-based resist materials are etchable with an oxygen plasma, the basic technique could be

extended to supplement other lithographic processes, including e-beam and X-ray processes, for fabricating both silicon and nonsilicon devices and circuits. 5 refs.

**096322 LDD MOSFET'S USING DISPOSABLE SIDEWALL SPACER TECHNOLOGY.** A technology for fabricating lightly doped drain (LDD) MOSFET devices based on disposable sidewall spacers is presented. Using a thin polysilicon buffer layer between the low-temperature oxide (LTO) sidewall spacers and the oxidized polysilicon gate, a single masking step can be used to form the n<sup>+</sup> and n<sup>+</sup> or p<sup>+</sup> and p<sup>+</sup> source/drain implants for the NMOS and PMOS devices, respectively. In addition, the LTO sidewall spacers may be removed by a wet HF strip, thus minimizing additional damage to the gate oxide that may be caused by reactive ion etch removal. The disposable sidewall spacer technology is easily adaptable to a CMOS process as demonstrated by the fabrication of a 4K × 4 SRAM circuit using a conventional 1.5-μm CMOS technology. 4 refs.

Pfister, James R. (Motorola, Austin, TX, USA). *IEEE Electron Device Lett* v 9 n 4 Apr 1988 p 189-192.

**096323 EFFECTS OF ION-BEAM MIXING ON THE PERFORMANCE AND RELIABILITY OF DEVICES WITH SELF-ALIGNED SILICIDE STRUCTURE.** The uniformity of Ti silicide resistance has been greatly improved by using an ion-beam mixing technique. The integrity of both MOS capacitors and p-n junction diodes has been improved. N-channel MOS field-effect transistors fabricated with this technique show better electrical characteristics, less electron trapping in the gate oxide, and better hot-carrier resistance than with devices made without the use of ion-beam mixing. 10 refs.

Ku, Y.H. (Univ of Texas, Austin, TX, USA); Lee, S.K.; Kwong, Dim-Lee; Lee, C.-O.; Yeagain, John R. *IEEE Electron Device Lett* v 9 n 6 Feb 1988, 34th Nucl Sci Symp, San Francisco, CA, USA, Oct 21-23 1987 p 293-295.

**096324 NEW MOSFET WITH LARGE-TILT-ANGLE IMPLANTED DRAIN (LATID) STRUCTURE.** The LATID device features the elimination of the sidewall spacer and self-alignment of n<sup>+</sup> large tilt angle (LAT) and n<sup>+</sup> implants to the same gate edge. Even without a spacer and a heavy drive-in, the LATID can achieve both a sufficiently long L<sub>eff</sub> and an n<sup>+</sup> gate overlap. The LATID achieves improved current drive by more than 50% and improved hot-carrier lifetime by more than three orders of magnitude as compared with a conventional lightly doped drain. The LATID technique is most promising for applications to submicrometer ULSI under 5-V operation. 11 refs.

Hori, Takashi (Matsushita Electric Industrial Co, Moriguchi, Jpn); Kurimoto, Kazumi. *IEEE Electron Device Lett* v 9 n 6 Feb 1988, 34th Nucl Sci Symp, San Francisco, CA, USA, Oct 21-23 1987 p 300-302.

**096325 COMPLEMENTARY METAL OXIDE SEMICONDUCTOR COMPATIBLE HIGH-VOLTAGE TRANSISTORS.** The purpose of this work was to study the implementation of high-voltage transistors using standard 3-5 μm complementary metal oxide semiconductor (CMOS) technology with a minimum of additional photolithographic or implant steps. A fabrication process was designed to accommodate a variety of high-voltage transistors with greater than 450 V breakdown voltage and low-voltage CMOS. Extensive use was made of a two-dimensional device model and a one-dimensional process model to determine suitable process parameters. The necessary conditions to produce a high-voltage double-diffused metal oxide semiconductor (DMOS) structure, as well as both n-well and p-well regions for CMOS transistors, and a thick gate oxide required to sustain the full blocking voltage were the main determinants of the process flow. Lateral DMOS (LDMOS),

vertical DMOS (VDMOS), conductivity modulated FET (COMFET), and MOS triac (TRIMOS) devices were fabricated on the same chip as standard CMOS transistors using the developed fabrication sequence. (Edited author abstract) 10 refs.

## Ionization

**096326 ACCURATE ANALYSIS OF IMPACT IONIZATION EFFECTS IN SUBMICROMETER MOSFET DEVICES.** The substrate current due to electron initiated impact ionization in submicrometer n-channel MOSFETs is calculated using a Monte Carlo (MC) simulation which uses the electrical field and current density distributions given by the PISCES conventional 2-D device modeling program. This method couples the physical precision of the MC technique with a conventional device modeling program based on the drift-diffusion approach. The MC simulation is therefore computationally efficient while still treating the details of high field transport correctly, and leads to an efficient and precise method for modeling submicrometer MOSFETs. 5 refs.

**Junctions** See Also ELECTRIC SWITCHES, SEMICONDUCTOR—Electric Power.

**096327 PLANAR p-n JUNCTION WITH NEAR IDEAL BREAKDOWN VOLTAGE.** MOSFETs are increasingly used as power devices and an important requirement of such a device is its ability to withstand high voltage. Since many MOS transistors have planar configuration, it is essential that the actual breakdown voltage of a planar junction is made to reach the bulk breakdown voltage. By using concentration profiling, a breakdown voltage of 91% of the bulk breakdown value is achieved. Numerical techniques were adopted to evaluate the field and the multiplication factor in the junction. The superiority of the method lies in its simplicity. (Edited author abstract) 9 refs.

Jog, Sujata (Indian Inst of Technology, Bombay, India); Sundar Singh, V.P. *Microelectron J* v 19 n 1 Jan-Feb 1988 p 41-47.

**096328 IMPROVING PN JUNCTION REVERSE RECOVERY MEASUREMENTS. PART 1.** Significant errors occur in measurement of the reverse recovery time of ultrafast rectifiers and Power MOSFETs. A primary cause is the inductance of the current-sampling resistor. A pertinent analysis is presented.

Leinfelder, Bernard A. (Bernar Corp). *Powerconverters Intell Motion* v 14 n 1 Jan 1988 p 41-44.

**096329 FORMATION OF SHALLOW p<sup>+</sup>-n JUNCTIONS USING BORON-NITRIDE SOLID DIFFUSION SOURCE.** The authors describe how shallow p<sup>+</sup>-n junctions on the order of 0.1 μm deep were fabricated using boron-nitride solid diffusion sources. The process used combines the hydrogen-injection method and rapid thermal processing. Sheet resistivities, in ranges from 50 to 130 Ω/sq with junction depths from 0.1 to 0.19 μm, are possible with this technique. Diode characteristics of 0.11-μm junctions show low reverse leakage current (of the order of 10 nA/cm<sup>2</sup>) indicating the possibility of this method's use to form PMOS source-drain contacts. 10 refs.

**096330 OPTIMIZATION OF THE GERMANIUM PREAMORPHIZATION CONDITIONS FOR SHAL-**

**LOW-JUNCTION FORMATION.** Shallow p<sup>+</sup>-n and n<sup>+</sup>-p junctions were formed in germanium preamorphized Si substrates. Germanium implantation was carried out over the energy range of 50-125 keV and at doses from 3 × 10<sup>14</sup> to 1 × 10<sup>15</sup> cm<sup>-2</sup>. p<sup>+</sup>-n junctions were formed by 10-keV boron implantation at a dose of 1 × 10<sup>15</sup> cm<sup>-2</sup>. Arsenic was implanted at 50 keV at a dose of 5 × 10<sup>15</sup> cm<sup>-2</sup> to form the n<sup>+</sup>-p junctions. Rapid thermal annealing was used for dopant activation and damage removal. Rutherford backscattering spectrometry was used to study the dependence of the amorphous layer formation on the energy and dose of germanium ion implantation. Cross-sectional transmission electron microscopy was used to study the residual defects formed due to preamorphization. Complete elimination of the residual end-of-range damage was achieved in samples preamorphized by 50-keV/1 × 10<sup>15</sup> cm<sup>-2</sup> germanium implantation. Areal and peripheral leakage current densities of the junctions were studied as a function of germanium implantation parameters. The results show that high-quality p<sup>+</sup>-n and n<sup>+</sup>-p junctions can be formed in germanium preamorphized substrates if the preamorphization conditions are optimized. 40 refs.

## Low Temperature Effects

**096331 50-ANGSTROM GATE-OXIDE MOSFET'S AT 77 K.** The mobility degradation and hot-carrier-induced degradation at 77 and 300 K in MOSFETs with very thin gate oxides are studied. Four oxide thicknesses, 52 angstrom, 92 angstrom, 152 angstrom, and 254 angstrom, are investigated, with an emphasis on 52 angstrom and 152 angstrom. All the devices are conventional n-channel MOSFETs without threshold adjustment implants. It is found that hot-carrier-induced degradation may not be the limiting factor in choosing the power-supply voltage, and special drain structures may be necessary for very thin gate MOSFETs even at 77 K. However, mobility reduction at high V<sub>G</sub> is more severe both at lower temperatures and for thinner oxides. Electron mobility appears to be oxide-thickness-dependent at 77 K. The dependence of the electron mobility on the normal field is so strong that it results in unusual I-V characteristics such as negative transconductance at 77 K for an oxide field above 3 MV/cm. The I-V characteristics have been modeled for 52 angstrom devices. 25 refs.

## Magnetic Field Effects

**096332 PHONON EMISSION BY A HOT TWO-DIMENSIONAL ELECTRON GAS IN A QUANTIZING MAGNETIC FIELD.** A detailed analysis is made of the acoustic phonon emission spectrum of a heated 2DEG in (0 0 1) n-Si inversion layer, when a quantizing magnetic field B is applied perpendicular to the layer. Particular attention is given to the case of high magnetic fields when only a few Landau levels are occupied. The emitted power is then quasimonochromatic at the cyclotron frequency. Both longitudinal and transverse modes are considered and the transition to zero field is discussed. (Edited author abstract) 19 refs.

Toombs, G.A. (Univ of Nottingham, Nottingham, Engl); Sheard, F.W.; Neilson, D.; Challis, L.J. *Solid State Commun* v 64 n 4 Oct 1987 p 577-581.

## Manufacture

**096333 MOSFET'S IN POLYCRYSTALLINE Si RECRYSTALLIZED WITH THE PROCESS OF SSIC - SEED SELECTION THROUGH ION CHANNELING.** This letter demonstrates the optimization for large grain poly-Si formation by Si ion implantation and subsequent recrystallization. When SSIC (seed selection

through ion channeling) occurs, the grain size becomes largest. A high quality poly-Si MOSFET was fabricated using SSIC process. (Author abstract) 5 refs.

Mizushima, Ichiro (Keio Univ, Yokohama, Jpn); Ohori, Kiyoshi; Itoh, Kenichi; Kuwano, Hiroshi. *Trans Inst Electron Inf Commun Eng Sect E (Engl)* v E70 n 11 Nov 1987, Pap from the 1987 Natl Conf on Semicond Devices and Mater IEICE, Kumamoto, Jpn, Nov 1-4 1987 p 1062-1064.

## Materials

**096334 VERTICAL-TYPE AMORPHOUS-SILICON MOSFET IC'S.** The performance of vertical-type amorphous-silicon (a-Si) MOSFETs has been improved significantly by using native silicon dioxide as the gate insulator. The maximum field-effect mobility was  $1.2 \text{ cm}^2/\text{V}\cdot\text{s}$ . An E/E-type inverter and a seven-stage ring oscillator have been fabricated by integrating the vertical-type a-Si MOSFET. The minimum propagation delay time was 95 ns/stage. The characteristics of a flip-flop circuit are also described. 10 refs.

Okada, Hiroyuki (Tokyo Inst of Technology, Tokyo, Jpn); Uchida, Yasutaka; Arai, Kazumasa; Oda, Shunji; Matsumura, Masakiyo. *IEEE Trans Electron Devices* v 35 n 7 Jul 1988 p 919-922.

**096335 CHARACTERISTICS OF MOSFET'S ON LARGE-GRAIN POLYSILICON FILMS.** Polysilicon transistors with improved characteristics are reported. Solid-phase crystallization of evaporated amorphous silicon is used to grow grains in the film up to  $3.5 \mu\text{m}$ . MOSFETs fabricated on this poly-Si film exhibit a carrier mobility of  $165 \text{ cm}^2/\text{V}\cdot\text{s}$  for electrons and  $69 \text{ cm}^2/\text{V}\cdot\text{cm}$  for holes. CMOS 100-stage inverter chains with propagation delay times of 400 ps/stage are demonstrated. The dependence of electrical characteristics on channel length is found and explained by the number of grain boundaries in the channel region. The results indicate that the characteristics of MOSFETs are improved if the grain size of the poly-Si film is as large as the device dimensions. All the devices fabricated are applicable to high-density VLSIs. 15 refs.

## Mathematical Models See Also ELECTRONS—Electric Field Effects.

**096336 OPTIMUM DESIGN OF VERTICAL POWER MOSFET WITH THICK DRAIN OXIDE.** The optimum design of a vertical power MOSFET with thick drain oxide is described, taking into account such characteristics as the on-resistance and breakdown voltage. Introducing the empirical ideality of the edge-termination which determines the breakdown voltage of the device, the optimum doping density and thickness of the epitaxial layer have been determined to minimize the on-resistance. Using two-dimensional simulation to evaluate the optimum design of the device, the thickness of the drain oxide and the relationship between the layout pitch and the product of on-resistance and active area have been determined. (Edited author abstract) 18 refs.

**096337 MODELING OF OHMIC MOSFET OPERATION AT VERY LOW TEMPERATURE.** A model for the ohmic operation of a MOS transistor at very low temperature (4-40 K) is presented. The model is based on a quantum treatment of the inversion layer and on a specific low temperature mobility law. It enables a good description of the MOSFET transfer characteristics (field effect mobility, drain current) as a function of gate voltage and predicts the temperature dependence of the maximum field effect mobility and of the threshold voltage. (Author abstract) 14 refs.

**096338 COMPARISON OF SOME METHODS FOR THE SOLUTION OF THE NONLINEAR POISSON EQUATION IN SEMICONDUCTOR DEVICE MODELLING.** This paper examines several modifications to Newton's method for the numerical solution of the nonlinear Poisson equation which describes the electrostatic potential distribution in a semiconductor device. Two methods for a more efficient solution of the equation when the device is a Metal-Oxide-Semiconductor Field Effect Transistor are proposed. Their extension to the solution of the fully coupled system of equations is also discussed. The modifications to Newton's method are also compared numerically. (Author abstract) 14 refs.

**096340 PSEUDO-TWO-DIMENSIONAL ANALYSIS OF SHORT CHANNEL MOSFETS.** A new version of a pseudo-two-dimensional analysis for the drain region of short channel MOSFETs is proposed. Second order effects such as mobility degradation, velocity saturation, and short channel effects are included in the analysis and the dependence on the processing parameters is taken into consideration. The model proposed in this paper guarantees the continuity of the output conductance and its derivative with respect to the drain voltage at the point of transition from the linear to the saturation region. The predictions of the model are confirmed by a comparison with the experimental data available in the literature. (Author abstract) 10 refs.

**096342 MOSFET MODEL WITH SUBSTRATE BIAS FOR CAD.** A simplified three-terminal MOSFET model for CAD is obtained by incorporating the black box method into the physical model of MOSFET, and then expanded to be a four-terminal MOSFET model by taking into account the effects of substrate bias, the modeling of which is also simplified. A computer program with optimization algorithms and least-square curve fitting technique has been used to determine the model parameters automatically. Only simple experimental measurements are required for parameter extraction. Simulated results obtained from the model with experimental data. (Edited author abstract) 9 refs. In Chinese.

**096343 THRESHOLD VOLTAGE MODELS OF THE NARROW-GATE EFFECT IN MICRON AND SUBMICRON MOSFETS.** Modeling of the narrow gate

effect on the threshold voltage shift ( $\Delta V_T$ ) and the effective channel width ( $W_{CE}$ ) by Ji and Sah, based on the solution of the Poisson equation for the two-dimensional (2-D) potential distribution using the depletion approximation, has been improved by removing the depletion approximation. A simple two-parameter analytical formula for predicting the threshold voltage shift of a narrow gate MOSFET with gate width ( $W_G$ ) in the micron and submicron ranges, was proposed and tested against 2-D numerical results. Both parameters can be extracted easily from the theoretical 2-D computed or experimental drain conductance-gate voltage characteristics. The new model shows that the threshold voltage shift of any given MOSFET with a known  $W_{CE}$  can be determined based only on one test device. Therefore, in applications, computation time can be reduced considerably by using the proposed analytical formula to compute the threshold voltage of any given MOSFET. (Edited author abstract) 25 refs.

**096344 THREE-PIECE MODEL OF CHANNEL LENGTH MODULATION IN SUBMICROMETER MOSFETS.** A simple model for the linear region of submicrometer n-channel MOSFETs is proposed in which the effective channel length of the device is considered as a function of applied gate and drain voltages, channel doping and temperature. The MOSFET channel is supposed to have three regions with different values of surface state density and oxide charge to take into account the processing-induced damages at its edges. The model is compared with the experimental results of device transconductance at room and low temperatures. It allows understanding of various results unaccounted for by standard models and offers a physical basis for more sophisticated modelling. (Edited author abstract) 23 refs.

**096345 ANALYTICAL MODELING OF TRANSFER ADMITTANCE IN SMALL MOSFETS AND APPLICATION TO INTERFACE STATE CHARACTERISATION.** A simple analytical model for the transfer admittance (dynamic transconductance) of MOS transistors is presented. This model establishes a direct correlation between the transfer admittance and the interface state admittance in an explicit analytical form. Experimental measurements have been performed and the obtained results with our theory. We present a new method for characterising interface states in MOS transistors of channel lengths less than  $10 \mu\text{m}$  from the measurement of the imaginary part of the inverse of the transfer admittance. (Edited author abstract) 11 refs.

**096346 THRESHOLD-VOLTAGE VARIATIONS IN VLSI MOSFETS DUE TO SHORT CHANNEL LENGTHS.** A simple model is derived for the threshold voltage of a MOSFET in a CMOS n-well or p-well process. The model includes the short-channel effects and considers a Gaussian distribution of the n-type implant in the n-well. An expression is derived based on the charge conservation principle for a case of low drain-source voltage  $V_{DS}$ , which geometrically takes into account the two-dimensional edge effects. The model is in agreement with the measured threshold voltages of typical CMOS (p-channel) transistors. The model is also in agreement with L.D. Yau's model (1974) in the limiting case of uniform channel doping. 4 refs.

**096347 SUBTHRESHOLD MODEL OF THE NARROW-GATE EFFECT IN MOSFETS.** The subthreshold softening characteristic of MOSFETs due to the narrow-gate effect has been investigated based on device physics and the two-dimensional (2-D) numerical solution of the Poisson equation. Numerical results taken on stepped-oxide MOSFETs with different gate widths show that a narrower-gate-width device tends to give higher cutoff voltage. Two parameters account for the softening of the subthreshold characteristics: the subthreshold slope of the drain conductance-gate voltage characteristic and the effective channel width. Both parameters can be extracted easily from the theoretical 2-D computed or experimental drain conductance-gate voltage characteristics. A two-parameter analytical approximation formula for narrow-gate MOSFETs operating in the subthreshold range is proposed and tested against exact 2-D numerical results, showing good accuracy. 20 refs.

**096350 NEW DISCRETIZATION STRATEGY OF THE SEMICONDUCTOR EQUATIONS COMPRISING MOMENTUM AND ENERGY BALANCE.** A discretization scheme is applied to the hydrodynamic model for semiconductor devices that generalizes the Scharfetter-Gummel method to both the momentum-conservation and the energy-conservation equations. The major advantages of the scheme are: (1) the discretization is carried out without neglecting any terms, thus providing a satisfactory description of such effects as velocity overshoot and carrier heating; and (2) the resulting equations lend themselves to a self-consistent solution procedure similar to those currently used to solve the simpler drift-diffusion equations. Two-dimensional steady-state simulations of an n-channel MOSFET and of an n-p-n BJT (bipolar junction transistor) have been carried out by means of an improved version of the program HFIELDS. Carrier-temperature plots have been obtained with a reasonable computational effort, demonstrating the efficiency of this technique. The results have been compared with those obtained with the standard drift-diffusion model and significant differences in the electron concentration have been found, especially at the drain end of the MOSFET channel. 29 refs.

**096351 ADAM: A TWO-DIMENSIONAL, TWO-CARRIER MOSFET SIMULATOR BASED ON GENERALIZED STREAM FUNCTIONS.** ADAM, a static MOSFET simulator based on a generalized stream function approach which automatically satisfies the continuity equations for full two-carrier transport, is described. This approach introduces a stream potential to account for source/sink terms in the continuity equations. The coupled, nonlinear equations are solved sequentially using H.K. Gummel's (1964) algorithm while the individual linear systems are solved using H.L. Stone's (1968) SIP method. Rectangular MOSFET geometries, which can include substrate insulation (SOS/SOI), can be simulated. Impurity profiles can be input from the SUPREM-3 (1-D) or ROMANS (2-D) process simulators. A multicomponent stream vector approach is used to treat the multiterminal current flow. Convergence of terminal currents occurs rapidly and leads to an efficient simulator in spite of the extra equations to be solved. The generalized stream function approach is described, along with boundary conditions and discretization. Simulation results are presented and the interpretation of the calculated stream functions discussed. 13 refs.

**096352 NONSTATIONARY CARRIER DYNAMICS IN QUARTER-MICRON SI MOSFETS.** An application of Monte Carlo particle and relaxation time approximation modeling to quarter-micron Si MOSFETs is presented. Through a comparison between these two nonstatic models and a conventional model, nonstationary carrier transport is shown to dominate in  $0.4 \mu\text{m}$  or less channel devices, with peak velocities exceeding  $1.0 \times 10^7 \text{ cm/s}$ . It is shown that the relaxation time approximation model tends to overestimate nonstationary carrier dynamics, especially the energy distribution. 10 refs.

**096353 VOLTAGE-DOPING TRANSFORMATION: A NEW APPROACH TO THE MODELING OF MOSFET SHORT-CHANNEL EFFECTS.** It is shown that the influence of the drain-source field on the potential barrier height is physically equivalent to and can be replaced by a reduction in channel doping concentration according to a formula derived from the two-dimensional Poisson equation. The actual barrier height for any drain bias and channel length, on which the derived equation depends, can be calculated easily using well-known one-dimensional (long-channel) solutions. This simple but general procedure, called the voltage-doping transformation (VDT), is shown to lead to analytically calculated potential distributions in fairly good agreement with two-dimensional numerical simulation. An application of the VDT to threshold voltage ( $V_{th}$ ) calculations also is shown. The  $V_{th}$  model is compared with measurements taken on implanted n-MOSFETs with various channel lengths. Good agreement demonstrates the accuracy of both the VDT and the new  $V_{th}$  model. 9 refs.

**096354 INVERSE-NARROW-WIDTH EFFECTS AND SMALL-GEOMETRY MOSFET THRESHOLD VOLTAGE MODEL.** An analytical threshold voltage model is developed based on the results from a three-dimensional MOSFET simulator, called MICROMOS. The model is derived by solving Poisson's equation analytically and is used to predict the threshold voltage of MOSFETs with fully recessed oxide isolation (the trench structure). Coupling was observed between the short-channel effect and the inverse-narrow-width effect. The coupling results from the mutual modulation of the depletion depth and is used to extend the analytical

inverse narrow-width model to small-geometry devices. The model is compared with experimental data obtained from the literature as well as with the three-dimensional simulator. Satisfactory agreement for channel lengths down to  $1.5 \mu\text{m}$  and channel widths down to  $1 \mu\text{m}$  has been obtained. 16 refs.

**096356 AUTOMATED PARAMETER EXTRACTION AND MODELING OF THE MOSFET BELOW THRESHOLD.** A subthreshold model for use in circuit simulation software is described. The model includes representation of nonuniform substrate impurity concentrations and short-channel and narrow-channel effects, while being simple in form. It has been developed in concert with an automated parameter-extraction methodology. The model adds only one parameter to the existing strong inversion model with which it is fully integrated. The accuracy and computational efficiency are suitable for circuit simulation. The results of an extraction carried out on nMOS transistors with channel widths from  $70$  to  $0.9 \mu\text{m}$  and channel lengths from  $35$  to  $1.25 \mu\text{m}$  over a wide range of bias conditions are described. 10 refs.

**096358 SEMI-EMPIRICAL MODEL FOR THE FIELD-EFFECT MOBILITY OF HYDROGENATED POLYCRYSTALLINE-SILICON MOSFETS.** The quantitative relationship between field-effect mobility ( $\mu_{FE}$ ) and grain-boundary trap-state density ( $N_t$ ) in hydrogenated polycrystalline-silicon (poly-Si) MOSFETs is investigated. The focus is on the field-effect mobility in MOSFETs with  $N_t$   $1 \times 10^{12} \text{ cm}^{-2}$ . It is found that reducing  $N_t$  to as low as  $5 \times 10^{11} \text{ cm}^{-2}$  has a great impact on  $\mu_{FE}$ . MOSFETs with  $N_t$  of  $4.2 \times 10^{11} \text{ cm}^{-2}$  show an electron mobility of  $185 \text{ cm}^2/\text{V}\cdot\text{s}$ , despite a mean grain size of  $0.5 \mu\text{m}$ . The three principal factors that determine  $\mu_{FE}$ , namely, the low-field mobility, the mobility degradation factor, and the trap-state density  $N_t$  are clarified. 15 refs.

**096359 POLYNOMIAL SPLINES FOR MOSFET MODEL APPROXIMATION.** The approximation of MOSFET nonlinearities by use of polynomial splines was investigated for reducing both circuit model development time and model simulation cost. After a brief tutorial on spline functions, it is shown how the number of independent variables for the MOSFET simulation models in digital circuits is reduced by their use. A tableau formulation for generating splines is presented along with a storage-reduction technique for polynomial spline coefficients. Mathematical programming problems for one-, two-, and three-dimensional splines are given that result in accurate monotonic splines using few segments. Two spline segments are shown to provide sufficient accuracy in the one-dimensional case, while  $4 \times 4$  and  $2 \times 5 \times 5$  segments provide sufficient accuracy in the two- and three-dimensional cases, respectively. 38 refs.

**096360 STATIC CHARACTERISTICS OF 2.3-NM GATE-OXIDE MOSFETS.** The static characteristics of experimentally fabricated 2.3-nm gate-oxide MOSFETs were reasonably fitted from the subthreshold to postthreshold region by a Pao-Sah double-integral MOSFET model modified with field-dependent mobility. Gate leakage current was negligibly small compared to drain current at the threshold voltage. 12 refs.

Nagai, Kiyoko (Electrotechnical Lab, Tsukuba, Jpn); Hayashi, Yutaka. *IEEE Trans Electron Devices* v 35 n 7 Jul 1988 p 1145-1147.

**096361 CONSIDERATION OF DOPING PROFILES IN MOSFET MOBILITY MODELING.** The channel mobility of a MOSFET in the strongly inverted, linear regime is an important parameter in this modeling process and depends on the effective normal electric field. It is shown that the general form of this field is  $E_{eff} = (\eta Q_c + \zeta Q_b)/\epsilon_{Si}$ , where  $Q_c$  and  $Q_b$  are the inversion- and bulk-charge area densities, respectively, and the coefficient  $\eta$  and  $\zeta$  determine the weighting of these charge densities. A recent study of p-channel MOSFET transistors indicates that  $\eta \approx 1/3$  and  $\zeta = 1$ , which implies that the inversion charge contribution is different for electrons and holes in MOSFETs. It is shown theoretically, by quantum mechanical arguments, that  $\zeta = 1/2$  for both n- and p-channel MOSFETs and the coefficient of the bulk-charge contribution  $\zeta$  depends on the doping profile in the near-surface region. A uniform doping profile produces a value of  $\zeta = 1$ , while a nonuniform profile near the interface leads to  $\zeta > 1$  (accumulation) or  $\zeta < 1$  (depletion). Experimental results to support these conclusions are reported. 8 refs.

**096363 IMPROVING THE ACCURACY OF THE CHARGE-SHEET MODEL FOR THE LONG-CHANNEL METAL-OXIDE SEMICONDUCTOR FIELD-EFFECT TRANSISTOR.** It is shown that the accuracy of the charge-sheet model for the long-channel metal-oxide-semiconductor field-effect transistor can be improved by allowing for the small potential drop across the inversion layer, and by using a more accurate analytic approximation for the charge stored in the depletion

region. These changes bring charge-sheet model to better than 1% agreement with the Pao-Sah model for typical devices and operating conditions. The proposed modifications do not significantly increase the computational complexity of the charge-sheet model. 9 refs.

## Measurements

**096364 DIRECT DEPLETION CAPACITANCE MEASUREMENT TECHNIQUE TO DETERMINE THE DOPING PROFILE UNDER THE GATE OF A MOSFET.** A technique to measure directly the depletion capacitance between the inversion layer and the substrate in the determination of the doping profile under the gate of a MOS device is described. The measurement technique is less sensitive to stray capacitance and can be carried out under steady-state conditions. The technique therefore lends itself to direct measurement on small-area devices, avoiding the need for large-area devices as in other techniques. Doping profiles obtained using this method on MOS transistors as small as  $W \times L = 18.8 \times 3.1 \mu m^2$  are compared with profiles obtained by the pulse method on large-area MOS capacitors. The comparison shows good agreement in the range where the technique is applicable. 11 refs.

Wikstrom, J.A. (Univ of California, Los Angeles, CA, USA); Viswanathan, C.R. *IEEE Trans Electron Devices* v ED-34 n 10 Oct 1987 p 2217-2219.

**096365 INVESTIGATION OF ELECTRON DRIFT VELOCITY IN MOSFETS USING A GRATING GATE ELECTRODE.** A technique was developed for measuring electron drift velocity versus lateral electric field in MOSFET inversion layers with normal electric field as an adjustable parameter. This technique uses MOS transistors whose gates consist of an aluminum grating with period (pitch)  $< 1.75 \mu m$ , spanning the width of the device. Each of the electrodes of the grating is independently accessible, allowing arbitrary voltages to be applied to them. In this manner, any gate voltage as a function of distance along the channel can be approximated discretely. A thick gate dielectric facilitates the smearing of the surface potentials due to each of the gate electrodes at the semiconductor surface making the potential variation smooth. With the ability to apply any arbitrary gate potential as a function of position, the surface potential and thus the inversion layer can be modulated so as to create a nearly uniform inversion charge for any given drain-to-source voltage, implying a nearly uniform tangential electric field. The normal field is then adjustable by adjusting the common offset voltage applied to all electrodes.

**096366 GATE-VOLTAGE-DEPENDENT EFFECTIVE CHANNEL LENGTH AND SERIES RESISTANCE OF LDD MOSFETS.** A measurement algorithm to extract the effective channel length and source-drain series resistance of MOSFETs is presented. This extraction algorithm is applicable to both conventional and LDD (lightly doped drain-source) MOSFETs. It is shown that the effective channel length and the source-drain series resistance of an LDD device are gate-voltage dependent. The effective channel length of an LDD device is not necessarily the metallurgical junction separation between the source and drain, as it is in a conventional device. A more generalized interpretation of effective channel length is introduced to understand the physical meaning of this gate-voltage dependence. The result also indicates that the effective channel length and source-drain resistance are two inseparable device parameters regardless of whether the devices in question are LDD or conventional FETs. 16 refs.

USA); Chang, Chi; Chia, Yu-Tai. *IEEE Trans Electron Devices* v ED-34 n 12 Dec 1987, 1987 IEEE Microwave and Millimeter-Wave Monolithic Circuits Symp, Jun 8-9 1987 p 2469-2475.

**096367 CHARACTERIZATION OF THE INVERSE-NARROW-WIDTH EFFECT.** The inverse-narrow-width effect - the reduction in the threshold voltage with decreasing device width - is modeled and experimentally measured. A fringing gate capacitance model is extended to include the effects of the sidewall interface charge. Two-dimensional and three-dimensional simulations are used to illustrate the enhanced sidewall potential and current, and also the effect of sidewall interface charge on the electrical behavior of MOSFETs with fully recessed isolation oxides. The authors compare the closed-form analytical threshold voltage expression developed with experimental data from small-geometry NMOS devices and find very good agreement. 13 refs.

**096369 EFFECTS OF ARSENIC DRAIN PROFILE ON SUBMICROMETER SALICIDE MOSFETS.** The performance and reliability tradeoffs with source-drain implant energy were examined on n-channel MOSFETs with 0.5- $\mu m$  physical gate lengths and fully silicided sources, drains, and gates. Platinum silicide was used over structures with self-aligned arsenic source-drain implants with energies ranging from 40 to 220 keV at a constant dose of  $1 \times 10^{14} cm^{-2}$ . Shallow implants showed low diode reverse breakdowns due to depletion layer interactions, but yielded low series resistance and underdiffusion ( $\Delta L$ ) values, and high device gains. Deeper implants ( $> 70 keV$ ) showed improved diode characteristics, but devices exhibited increased series resistance,  $\Delta L$ , and reduced gains. Only minor short-channel effects were noted on threshold voltage and subthreshold swings for channel devices with  $L = 0.5 \mu m$  over the range of implants examined, although the higher-energy implants did show more severe drain modulation effects. Significantly improved immunity to hot-carrier degradation was noted with the deeper implants. The drains implanted at 145 keV showed the best immunity to hot-electron degradation, small gain, and short-channel effects, giving a good balance between device performance and reliability. 23 refs.

**096370 RELATIONSHIP BETWEEN GATE BIAS AND HOT-CARRIER-INDUCED INSTABILITIES IN BURIED- AND SURFACE-CHANNEL MOSFETS.** For accurate predictions of device reliability with respect to hot-carrier effects, it is necessary to establish worst-case stress bias conditions. Detailed measurements of hot-carrier-induced instabilities in short-channel pMOSFETs have revealed that stress gate bias conditions corresponding to peak gate currents result in maximum

shifts in device parameters. However, for some parameters, notably those measured at low drain bias, comparable shifts are observed for stress gate bias conditions that correspond to peak substrate currents. These observations are valid for both buried-channel (n-type polysilicon gate) and surface-channel (p-type polysilicon gate) pMOSFETs. An interpretation of these results based on the generation of trapped oxide charge and interface traps is proposed. 6 refs.

**096371 ON THE EFFECT OF HOT-CARRIER STRESSING ON MOSFET TERMINAL CAPACITANCES.** The hot-carrier effect on the MOSFET is studied by measuring the terminal capacitances of a MOSFET before and after bias voltage stressing. It is concluded that under DC bias stressing, hot electrons are trapped near the drain end of the device. Capacitance observations can be understood in terms of a model in which the trapped-electron distribution peaks very close to the drain-channel metallurgical junction. 6 refs.

## Microwaves

**096372 EXPLOIT ADVANTAGES OF POWER FETs FOR L-BAND USE.** A double diffused MOSFET (DMOSFET) fabricated in silicon has been developed that brings real power to L-band frequencies for the first time. The DMOSFET's linear common-source operation makes simple control of gain and power output possible since the device can deliver linear broadband amplification of waveforms with complex modulation schemes. Ease of bias and resistance to thermal runaway make the DMOSFET a superior building block for complex military system applications. (Edited author abstract)

## Modeling

**096373 MOSFET MODEL CONTINUOUS FROM WEAK TO STRONG INVERSION.** A simple analytical model is proposed for long-channel MOSFETs. The model describes MOSFET operation in all regions from weak to strong inversion by a single exponential equation. This makes its implementation in CAD easy and time-saving. Predicted and experimental data are in good agreement. (Author abstract) 4 refs.

**096374 NEW BORON IMPLANTATION MODEL SUITABLE FOR ANALYTICAL MODELING OF THRESHOLD VOLTAGE OF MOSFETS.** The boron implantation profile in silicon is usually simulated by the Pearson-IV distribution function with some modifications, as in SUPREM. But this function is complex from the point of view of analytical modeling. New functions which fit well with SUPREM simulated implantation profiles for boron in silicon have been proposed. These functions, being analytically integrable, allow us to formulate accurate analytical models of threshold voltages of MOSFETs with implanted channels. Models for the threshold voltages of both long channel and short channel NMOSFETs have been presented. For the long channel case, the results agree with those obtained from numerical computations with considerable saving of computation time. The results of the short channel model also show good agreement with available experimental data. (Edited author abstract) 10 refs.

## Noise

**096376 DETERMINATION OF INTERFACE STATE DENSITY ESPECIALLY AT THE BAND EDGES BY NOISE MEASUREMENTS ON MOSFETS.** There are several experimental methods of measuring interface state densities on Si/SiO<sub>2</sub> interfaces. Up to now none of them has been able to provide information about the states within 0.1 eV near the band edges. However measurements of flicker or 1/f noise on MOSFETs allow interface state densities to be determined not only in the whole band gap but also within the bands. (Author abstract) 18 refs.

Jaentsch, O. (Siemens AG, Munich, West Ger); Borchert, B. *Solid State Electron* v 30 n 10 Oct 1987 p 1013-1015.

**096377 SIMPLE DERIVATION OF REIMBOLD'S DRAIN CURRENT SPECTRUM FORMULA FOR FLICKER NOISE IN MOSFETS.** A simple derivation of Reimbold's drain current spectrum formula is obtained from the usual input voltage spectral density for flicker noise in MOS transistors. The demonstration relies on a general expression of the MOSFET transconductance. Complete equivalence between approaches based on drain current or input voltage noise spectral densities is emphasized. (Author abstract) 7 refs.

**096378 EXCESS NOISE IN BURIED-CHANNEL MOS TRANSISTORS.** A definitive experiment is described on the excess noise in a buried-channel MOS transistor. The specimen was biased with a uniform, Ohmic, channel. With the surface enhanced 1/f noise is produced. With the surface depleted or inverted the noise drops by more than two orders of magnitude and takes on the character of the 1/f noise observed in JFETs. Also seen is a large generation-recombination noise peak involving the fast surface states. The implications for excess noise theory and device design are discussed. (Author abstract) 8 refs.

**096379 THERMAL ACTIVATION MODEL FOR 1/f NOISE IN SI-MOSFETS.** Measurements of the temperature dependence of noise power spectra in a series of commercial p-channel MOSFETs are presented. It was found that both the magnitude and the functional form of the voltage noise power spectral density varied greatly in the range between 60 and 260 K. The experimental results were compared to first-principle calculations which showed that the noise was due to the capture and emission of carriers by oxide traps through thermal activation. The process caused fluctuations in both the density and the surface mobility of the channel carriers through the modulation of the surface potential and the scattering rate, respectively. (Author abstract) 18 refs.

Surya, Charles (Univ of Rochester, Rochester, NY, USA); Hsiang, Thomas Y. *Solid State Electron* v 31 n 5 May 1988 p 959-964.

**096380 1/f NOISE IN (100) n-CHANNEL SI-MOSFETS FROM T=4.2 K TO T=295 K.** We have measured the 1/f-noise in the drain current of n-channel (100)

Si-MOSFET in the temperature range 4.2 K-295 K as a function of drain voltage. At T=4.2 K the 1/f-noise has also been measured as a function of gate voltage. At temperatures above T=130 K two noise sources contribute to the 1/f-noise: a McWhorter-like number fluctuations noise source and a mobility fluctuations noise source. We distinguished between the two sources on the basis of the different dependences of the noises on the electric field. Between 4.2 and 130 K the 1/f-noise is interpreted as number fluctuations noise. A maximum is observed between 50 and 70 K. At T=4.2 K we could not distinguish between the two sources. At low drain voltages there is a linear relationship between the gate voltage and the ratio of the square of the drain current to the 1/f-noise. The 1/f-noise as a function of drain voltage at T=4.2 K could be analyzed with the same two-valley model as that used for the analysis of the drain current-drain voltage characteristics. (Author abstract) 22 refs.

## Noise, Spurious Signal

**096381 DIFFUSION AND INTER-VALLEY NOISE IN (100) n-CHANNEL SI-MOSFETS FROM T=4.2 TO 295 K.** Noise in the drain current of (100) n-channel Si-MOSFETs was investigated as a function of both source-drain voltage and gate voltage, from T=4.2 to 295 K. The frequency range covered was from 1 to 250 kHz. Three contributions to the noise could be distinguished: 1/f-noise, generation-recombination noise and white noise. This paper deals mainly with the white noise component. The current-voltage characteristics at T=295 K can be described by simple MOSFET-theory, but at T=4.2 K hot carrier effects and field-induced transitions occur, and theory has to be amended accordingly. The white noise was measured at room temperature in diffusion noise. We also observed extra white noise at intermediate temperatures but it was less pronounced. We have developed a model which interprets this extra noise as the frequency-independent part of generation-recombination noise caused by inter-valley transitions between three groups of valleys. There is good agreement between the model and our experimental results. (Author abstract) 27 refs.

## Nondestructive Examination

**096382 NON-DESTRUCT TESTER DETERMINES POWER MOSFETS UIS LIMITS. PART 2.** A UIS non-destruct test fixture is described whose new crowbar response time is much faster than the previous design, 50 nsec relative to 200 nsec. Preliminary testing shows that the UIS failure mode for older high voltage power MOSFETs is apparently due to an instantaneous, critical drain current phenomenon independent of the size of the unclamped inductance. (Author abstract) 4 refs.

Pshaenich, Al (Motorola). *Powerconverters Intell Motion* v 13 n 10 Oct 1987 p 35-36, 38, 40-41.

**096383 ANALYSIS OF NONPLANAR DSA MOS (V-MOS) TRANSISTOR BY CAPACITANCE MEASUREMENTS.** A nondestructive method to determine the parameter of the DSA transistor by capacitance measurement is proposed. Determined parameters are the gate oxide thickness the drain impurity density, the drain area, the drain flat-band voltage, and the lateral profile along the channel which is one of the features of the DSA MOS transistor. In this method, both depletion and inversion characteristics of gate-drain capacitance are analyzed mainly by fitting them to the measured characteristics. (Edited author abstract) 7 refs.

## Optimization

**096384 OPTIMIZATION OF THE DRIFT REGION OF POWER MOSFET'S WITH LATERAL STRUCTURES AND DEEP JUNCTIONS.** The electric field profile in the drift region of power MOSFETs with lateral structures and deep junctions has been found analytically. From the analysis, the best uniform surface doping density and depth of the drift region in offset-gate power MOSFETs that introduces the minimum series resistance and sustains a given junction breakdown voltage is derived. Design guidelines for such MOSFETs are proposed. Comparison with computer simulation results has shown that it is reasonable for some practical structures. 12 refs.

**096385 OPTIMIZATION OF LDD MOSFET'S USING COUPLED 2-D SIMULATIONS.** During the design of p-channel LDD (lightly doped drain) devices for a CMOS technology, it was discovered that conventional LDD spacer design used for n-devices fails to give LDD structure to p-devices. Much wider spacers are required to create LDD p-channel devices. Detailed study of anisotropic etching of oxide used to define the LDD spacers showed that the spacers are not completely vertical and boron implant used in p+ source-drain region of p-devices scatters underneath the spacers. A complete two-dimensional computer simulation of the process and resulting device structure was done using SAMPLE (etching and lithography simulator), MEMBRE (two-dimensional process simulator) and PISCES (two-dimensional device simulator) in coupled form. Implant doses, temperature cycles, and spacer widths were optimized for breakdown voltage, Miller capacitance, and  $ID_{SAT}$  for both n- and p-devices simultaneously. Experimental data agreed well with the simulations. 2 refs.

## Performance

**096386 INSTRUMENTATION AMP IS FAST AND VERY ACCURATE.** Finding an instrumentation amplifier that can handle fast millivolt-level signals accurately, especially when the signals are floating on high common-mode voltages at high impedances, usually leaves system designers feeling exasperated. They have to resort either to in-house designs or to hybrid, modular, or even rack-mounted devices. A JFET-input instrumentation amplifier chip is reported.

**096390 SIPMOS DEPLETION TRANSISTORS CONDUCT WITHOUT GATE SIGNALS.** SIPMOS depletion-type transistors, also called normally on transistors, conduct without a gate signal applied. The relatively abrupt transition from the resistive to the pentode region allows many circuit designs to be greatly simplified by use of this transistor type. The device is ideal for use as a current limiter, constant power source or dc and ac current switch. (Author abstract)

Kaifler, Erich (Siemens AG, Munich, West Ger). *Siemens Compon* v 22 n 3 Jun 1987 p 104-107.

**096391 CRITERIA FOR ESTIMATING THE IMPACT OF SERIES RESISTANCE ON MOSFET PERFORMANCE.** We derive simple engineering criteria which may be used as a guideline in MOSFET design. In particular, with respect to series resistance it is clear that a too high  $R_S$  value is detrimental to device performance. On the other hand, pressing for a value which is lower than necessary may call for other unwelcome features (e.g. too deep junctions). Hence, a means for estimating the allowed  $R_S$  values is of prime importance. We show how such criteria may be obtained and used for estimating the necessary quantities. (Author abstract) 12 refs.

**096392 POWER MOSFETs IMPROVE BRUSHLESS DC MOTOR DRIVES.** Improvements in the drain-source diode of fourth-generation Power MOSFETs have enhanced the use of these devices in brushless DC motor drives. The drain-source diode's reverse-recovery time is now reduced to that of discrete diodes. Better ruggedness now virtually eliminates Commutating SOA limitations. Accompanying the diode improvements are ON-resistances below 40m $\Omega$  in TO-220 packages, which will significantly influence the use of power transistors in motor-drive output stages. In low-voltage brushless drives, the new device characteristics tip the balance of tradeoffs for power-device selection. As opposed to PNP bipolars or P-channel MOSFETs, N-channel MOSFETs are now the best choice for upper half-bridge positions. Similarly, SENSEFETs are the devices of choice for lower half-bridge positions.

Schultz, Warren (Motorola Inc). *Powerconverters Intell Motion* v 14 n 1 Jan 1988 p 52-54, 56.

**096393 POWER MOSFETs UNDERGO 60V GATE-RUPTURE TEST.** A markedly increased gate-rupture voltage capability is the result of a process improvement that Motorola applies to its TMOS Series products. It is also a major technological achievement in the power MOSFET realm. The process has been dubbed 'Bullet-Proof' to indicate the added ruggedness and to induce an inherently higher user confidence in the reliability of power MOSFET components. The gate-voltage improvements result in more reliable devices, because their gate-rupture voltage is higher.

Schulz, Werner (PCIM, Ventura, CA, USA). *Powerconverters Intell Motion* v 14 n 1 Jan 1988 p 58.

**096394 DYNAMIC PERFORMANCE OF CURRENT-SENSING POWER MOSFETs.** Errors in the output of current-sensing MOSFETs during switching are either perceived, due to measurement difficulties, or real, due to a change in sense ratio as the device passes from the linear to the fully enhanced region. Transformer action within the device package also produces transients and limits bandwidth. (Author abstract). 1 Ref.

**096395 POWER MOSFET PACKAGES TAKE NEW DIRECTIONS.** Higher voltages, lower on-resistances and new fabrication processes have captured most of the spotlight in power MOSFETs the past few years. It is pointed out that in the last year, developments in packages for these semiconductors have also come to share center stage. The packages have become smaller, more amenable to modern assembly processes, more thermally efficient, and better able to maximize the parts' performance potential for many applications. User demands for switching more power at higher frequencies - such as in the military - call for even better heat dissipation and control of factors like parasitic inductance than traditional power MOSFETs can handle. To squeeze out the higher speed and power, MOSFET makers are now turning to the package.

Chin, Spencer (Electronic Products, Garden City, NY, USA). *Electron Prod (Garden City NY)* v 31 n 8 Sep 15 1988 p 35-38.

**096396 ON THE PERFORMANCE LIMIT FOR SI MOSFET'S: EXPERIMENTAL STUDY.** Short-channel MOSFETs fabricated by direct-write electron-beam lithography have been examined with regard to parameters such as channel length, oxide thickness, and substrate doping concentration. A simple relationship between channel length and transconductance in the saturated region has been derived from the experimental results, and the performance of MOSFETs with zero channel lengths has been evaluated as a function of oxide thickness. The ultimate performance of MOSFETs with both zero channel length and zero oxide thickness has been estimated to be about 3000 mS/mm. This limitation is attributed to the saturation velocity and the finite inversion layer thickness. The electron saturation velocity in the inversion layer has been confirmed experimentally to be  $1.0 \times 10^7$  cm/s. 12 refs.

## Radiation Damage

**096397 RADIATION DAMAGE IN MOS TRANSISTORS AS A FUNCTION OF THE ANGLE BETWEEN AN APPLIED ELECTRIC FIELD AND VARIOUS INCIDENT RADIATIONS (PROTONS, ELECTRONS, AND CO-60 GAMMA RAYS).** Data are presented that show that ionizing radiation damage produced by 2-to-16-MeV protons in MOS transistors, with applied electrical fields across the gate oxides, is dependent on the angle between the fields and the incident protons. This angular dependency can be explained by the columnar recombination mode. For <sup>60</sup>Co photons and 5-to-20-MeV electrons, the data show no angular dependency. 8 refs.

Tallon, R.W. (US Air Force Weapons Lab, Kirtland AFB, NM, USA); Kemp, W.T.; Ackermann, M.R.; Owen, M.H.; Hoffland, A.H. *IEEE Trans Nucl Sci* v NS-34 n 6 Dec 1987, 1987 Annu Conf on Nucl and Space Radiat Eff, Snowmass Village, CO, USA, Jul 28-31 1987 p 1208-1213.

**Radiation Effects** See Also MICROELECTRONICS—Radiation Effects; SEMICONDUCTOR DEVICES—Radiation Effects.

**096398 COMPARISON OF PROTON AND NEUTRON CARRIER REMOVAL RATES.** Displacement-damage-induced carrier removal rates for proton irradiations in the energy range 10-175 MeV were compared to 1-MeV-equivalent neutrons using power MOSFETs as a test vehicle. The results showed that, within experimental error, the degradation mechanisms were qualitatively similar and that the ratio of proton-to-neutron carrier removal rates as a function of proton energy correlate with a calculation based on nonionization energy loss in silicon. For exposures under junction bias, p-type silicon was found to have a smaller carrier removal rate for both proton and neutron irradiations, whereas, for n-type silicon, junction bias had little effect on the carrier removal rate. 8 refs.

Pease, R.L. (Mission Research Corp, Albuquerque, NM, USA); Enlow, E.W.; Dinger, G.L.; Marshall, Paul. *IEEE Trans Nucl Sci* v NS-34 n 6 Dec 1987, 1987 Annu Conf on Nucl and Space Radiat Eff, Snowmass Village, CO, USA, Jul 28-31 1987 p 1140-1146.

**096399 REEVALUATION OF WORST-CASE POSTIRRADIATION RESPONSE FOR HARDENED MOS TRANSISTORS.** The worst-case postirradiation response of hardened n-channel transistors following Co-60 exposure to total dose levels of system interest is demonstrated to occur for 0-V bias during radiation, and positive bias during a subsequent anneal. This observation is explained in terms of oxide-trapped and interface-state charge buildup and anneal. Additional results are presented which suggest that, for future technologies with very thin gate oxides, worst-case device leakage during irradiation may well occur for 0-V irradiations. The authors discuss the importance of periodically reevaluating the response of MOS devices during and after irradiation to determine worst-case test conditions, particularly as technologies advance and gate insulators become thinner. 33 refs.

Fleetwood, D.M. (Sandia Natl Lab, Albuquerque, NM, USA); Dressendorfer, P.V.; Turpin, D.C. *IEEE Trans Nucl Sci* v NS-34 n 6 Dec 1987, 1987 Annu Conf on Nucl and Space Radiat Eff, Snowmass Village, CO, USA, Jul 28-31 1987 p 1178-1183.

**096400 POST-IRRADIATION EFFECTS IN FIELD-OXIDE ISOLATION STRUCTURES.** The authors have studied experimentally the time dependence of leakage currents in six CMOS (complementary metal-oxide semiconductor) processes using LOCOS (local oxidation of silicon) isolation structures. These six process lines represent six different US semiconductor companies. In their radiation response, these processes range from very hard to very soft. In the softer processes, the radiation-induced leakage currents are due to the turning on of a leakage path either under the thick field oxide or along the transistor edge (bird's beak) region. In the hardest process, the field oxide did not turn on, and the leakage was entirely due to subthreshold current in the gate region. These different mechanisms have qualitatively different time dependences, which are discussed along with the implications of the results for hardness assurance testing. 17 refs.

Oldham, T.R. (US Army Lab Command, Adelphi, MD, USA); Lelis, A.J.; Boesch, H.E.; Benedetto, J.M.; McLean, F.B.; McGarrity, J.M. *IEEE Trans Nucl Sci* v NS-34 n 6 Dec 1987, 1987 Annu Conf on Nucl and Space Radiat Eff, Snowmass Village, CO, USA, Jul 28-31 1987 p 1184-1189.

**096401 ANALYTICAL MODEL FOR THE SINGLE EVENT BURNOUT OF POWER MOSFETS.** The processes causing single-event burnout in power MOSFETs are modeled analytically, describing the evolution of the plasma filament from an ion traversing the structure and the processes constituting the triggering mechanism of second breakdown. Analytically tractable models are achieved by using simplifying approximations in common use in established semiconductor device theory, and by using initial conditions and parameters typical for simulations of single-event upset phenomena. Comparative simplicity and tractability is favored over accuracy to gain

lucid relationships between pertinent parameters, which can guide device design and optimization, aid the interpretation of results from simulation and experiment, and help in the development of simulation software. 12 refs.

**096402 GENERATION OF INTERFACE STATES BY IONIZING RADIATION AT 80K MEASURED BY CHARGE PUMPING AND SUBTHRESHOLD SLOPE TECHNIQUES.** Generation of fast interface states  $D_i$  by ionizing radiation has been measured in MOS transistors at 80K and 295K using charge pumping and subthreshold slope techniques. Using charge pumping, the more sensitive and reliable technique, it has been found that  $D_i$  are not formed by radiation at 80K. In contrast, subthreshold slope measurements appear to show an increase in  $D_i$  in MOSFETs irradiated at 80K. This is shown to be an artifact caused by lateral nonuniformities (LNU) in the radiation-induced fixed charge. 27 refs.

**096403 TEMPERATURE-INDUCED REBOUND IN POWER MOSFETS.** Enhancement-mode n-channel power MOSFETs were investigated for rebound. They received a 300 krad(Si) dose of gamma radiation under positive gate bias with source and drain grounded. The irradiated transistors were thermally annealed with all terminals shorted or under positive gate bias with drain and source shorted, at temperatures from 60°C to 150°C. Threshold-voltage rebound was observed for some transistor types under certain experimental conditions. 19 refs.

Singh, Gurbax (NBS, Gaithersburg, MD, USA); Galloway, Kenneth F.; Russell, Thomas J. *IEEE Trans Nucl Sci* v NS-34 n 6 Dec 1987, 1987 Annu Conf on Nucl and Space Radiat Eff, Snowmass Village, CO, USA, Jul 28-31 1987 p 1366-1371.

**096404 MODELING TRANSIENT RADIATION EFFECTS IN POWER MOSFETS.** Using standard device specifications and simple assumptions, the transient radiation response of vertical-conduction double-diffused metal-oxide-semiconductor (VDMOS) MOSFETs can be modeled in a standard circuit analysis program. The device model consists of a body diode, a parasitic bipolar transistor, and elements to simulate high-current reduced breakdown. The proposed photocurrent model emulates response to any pulse shape and accounts for bias-dependent depletion regions. The model can be optimized to best fit available test data. 8 refs.

Hoffman, J. Russell (Martin Marietta Aerospace, Denver, CO, USA); Hall, Wallace E.; Dunn, Douglas E. *IEEE Trans Nucl Sci* v NS-34 n 6 Dec 1987, 1987 Annu Conf on Nucl and Space Radiat Eff, Snowmass Village, CO, USA, Jul 28-31 1987 p 1381-1385.

**096405 PROPAGATION DELAY MEASUREMENTS FROM A TIMING SAMPLER INTENDED FOR USE IN SPACE.** A 3- $\mu$ m CMOS timing sampler is described which is a test circuit designed into the Jet Propulsion Labs' CRRES chip to be flown on the Combined Release and Radiation Effects Satellite (CRRES). The timing sampler consists of 64 inverter-pair stages with sampling latches and decoder circuitry. The sampler is used to measure inverter-pair propagation delays, which are nominally 2.5 ns, with a resolution of 100 ps. A simple model was developed to explain the radiation-induced inverter-pair delay shifts in terms of radiation-induced MOSFET threshold-voltage shifts and effective modal capacitances. The magnitude of the shift in pair delay with radiation was estimated at the point where the n-MOSFET threshold voltage became zero. For a 0.7-V-threshold shift, the pair delay increased from its preradiation value by 360 ps for a rising step input and

decreased by 190 ps for a falling step input. 11 refs.

Blaes, B.R. (JPL, Pasadena, CA, USA); Buehler, M.G.; Lin, Y.-S. *IEEE Trans Nucl Sci* v NS-34 n 6 Dec 1987, 1987 Annu Conf on Nucl and Space Radiat Eff, Snowmass Village, CO, USA, Jul 28-31 1987 p 1470-1473.

**096406 EVALUATION OF LOW-ENERGY X-RAY AND COBALT-60 IRRADIATIONS OF MOS TRANSISTORS.** An evaluation of methodologies for irradiating MOS transistors with low-energy X-ray and  $^{60}\text{Co}$  sources has been performed. It has been found that comparisons of voltage shifts produced by bulk trapped-charge and interface states in MOS transistors irradiated using two different low-energy X-ray sources (an ARACOR 10-keV W source and an 8-keV Cu source) agree to within better than 30%. This quality of agreement is similar in magnitude to that between MOS devices irradiated by different  $^{60}\text{Co}$  sources. In contrast, the measurements indicate that interlaboratory comparisons of ratios of shifts produced by X-ray and  $^{60}\text{Co}$  sources can lead to differences in ratios as large as a factor of approximately 1.7. Improved electron-hole recombination data for oxides is presented. This recombination correction, in conjunction with a correction for interface dose enhancement, is used to predict the ratios of shifts produced by X-ray and  $^{60}\text{Co}$  sources. However, the results show that corrections for electron-hole recombination and interface dose enhancement do not, by themselves, adequately predict the field-dependent behavior of these transistors. 20 refs.

**096407 RADIATION EFFECTS IN LDD MOS DEVICES.** The purpose of this work is to investigate the response of lightly doped drain (LDD) n-channel transistors to ionizing radiation. Transistors were fabricated with conventional (non-LDD) and LDD structures using both standard (nonhardened) and radiation-hardened gate oxides. Characterization of the transistors began with a correlation of the total-dose effects due to 10-keV X-rays and  $^{60}\text{Co}$  gamma rays. It was determined that the radiation response of LDD transistors is similar to that of conventional transistors. Both standard and radiation-hardened transistors subjected to hot-carrier stress before irradiation show a similar radiation response. After exposure to  $1.0 \times 10^6$  rads(Si), nonhardened transistors show increased susceptibility to hot-carrier degradation, while the radiation-hardened transistors exhibit similar hot-carrier degradation to nonirradiated devices. The authors demonstrated a fully-integrated radiation hardened process that is solid to  $1.0 \times 10^6$  rads(Si), and shows promise for achieving  $1.0 \times 10^7$  rad(Si) total-dose capability. 11 refs.

**096408 MODEL DESCRIBING HOT-CARRIER AND RADIATION EFFECTS IN MOS TRANSISTORS.** Data that describe the magnitude and type of damage created in MOS transistors by hot-carrier and ionizing-radiation environments are presented. The interaction of the effects of these types of damage is described by a qualitative model that divides the damage into two damage regions. 6 refs.

McBrayer, J.D. (Sandia Natl Lab, Albuquerque, NM, USA); Pastorek, R.A.; Jones, R.V.; Ochoa, A. Jr. *IEEE Trans Nucl Sci* v NS-34 n 6 Dec 1987, 1987 Annu Conf on Nucl and Space Radiat Eff, Snowmass Village, CO, USA, Jul 28-31 1987 p 1647-1651.

**096409 RADIATION-TOLERANT, SIDEWALL-HARDENED SOI/MOS TRANSISTORS.** Total dose radiation effects were measured for sidewall-hardened n-channel silicon-on-insulator (SOI)/MOS transistors, fabricated in zone-melt-recrystallized (ZMR) and oxygen-implanted (SIMOX) SOI materials. The radiation responses of transistors are compared with three types of sidewall or edge configurations: island transistors with passivated edges, island transistors without passivated edges, and edgeless (enclosed-gate) transistors. Data from these three test devices allow clear separation of front-, back-, and edge-channel conduction. Passivated edge channels were hard to  $^{60}\text{Co}$  doses in excess of 24 Mrad(Si). The overall hardness of the passivated-edge transistors is limited only by the radiation-induced threshold voltage shifts (about  $-1\text{ V}$  at  $1.0\text{ Mrad}$ ) of the top channel. No significant differences in total-dose response of ZMR and SIMOX devices were observed under the radiation conditions used. 21 refs.

**096410 TOTAL DOSE HARDENING OF BURIED INSULATOR IN IMPLANTED SILICON-ON-INSULATOR STRUCTURES.** Total dose characteristics of the buried insulator in implanted silicon-on-insulator (SOI) substrates have been studied using MOS transistors. The threshold-voltage shift of the parasitic back-channel transistor, which is controlled by charge trapping in the buried insulator, is reduced by lowering the oxygen dose as well as by an additional nitrogen implant, without degrading the front-channel transistor characteristics. The improvements in the radiation characteristics of the buried insulator are attributed to the decrease in the buried oxide thickness or to the presence of the interfacial oxynitride layer formed by the oxygen and nitrogen implants. 12 refs.

**096412 PROGRAMMABLE TEST SYSTEM FOR TRANSIENT ANNEALING CHARACTERIZATION OF IRRADIATED MOSFETS.** A current-programmable, computer-controlled transient annealing test system (TATS) for making complete MOSFET I-V measurements is described. The system forces source currents from  $100\text{ pA}$  to  $10\text{ mA}$  and measures corresponding gate voltages starting at times as early as  $100\text{ }\mu\text{s}$  after a radiation pulse. Features of the system include multiple independent test channels, temperature control over the full military range, and completely programmable test/bias sequences. Applications of the system include: a) transient-failure-mechanism studies, b) in-source testing, and c) high-throughput wafer-level hardness-assurance testing. 5 refs.

**096413 HEAVY-ION-INDUCED, GATE-RUPTURE IN POWER MOSFETS.** A heavy-ion-induced burnout mechanism has been experimentally observed in power metal-oxide-semiconductor field-effect transistors (MOSFETs). This mechanism occurs when a heavy charged particle passes through the gate oxide region of n-channel or p-channel devices having sufficient gate-to-source or gate-to-drain bias. The gate rupture leads to significant permanent degradation of the device. A proposed failure mechanism is discussed and experimentally verified. The absolute immunity of p-channel devices to heavy-ion-induced semiconductor burnout is demonstrated and discussed along with nondestructive burnout testing methods. 3 refs.

**096414 SEU SENSITIVITY OF POWER CONVERTERS WITH MOSFETS IN SPACE.** Results of an investigation into the survivability of power MOSFETs in space are reported. 72 of these devices are presently in geosynchronous orbit aboard six communications spacecraft, and operating at  $70\text{ V}$ , which is 70% of the nominal breakdown voltage. No failures have occurred after 94536 device-days in space. The irradiation of discrete parts as well as the prototype flight power converter, containing the same part types, by iron particles with a LET (linear energy transfer) of  $10\text{ MeV-cm}^2\text{mg}$ , and an iron spectrum with a maximum LET of 26 showed these high-reliability flight parts to be relatively harder than the same type of devices previously ground tested. This appears to be the explanation for the lack of failures in space. 4 refs.

#### Semiconductor Insulator Boundaries

**096417 THERMIONIC EMISSION PROBABILITY FOR SEMICONDUCTOR-INSULATOR INTERFACES.** Simulation of hot-carrier gate-current effects in either MOSFET or MODFET devices requires knowledge of the carrier-emission probability over the semiconductor-insulator barrier. Several recent studies have relied on a limiting form for this probability that can lead to significant errors for large fields in the Si-SiO<sub>2</sub> system. It

is shown that the result for emission probability can be expressed as an error function, leading to simple implementation in the numerical 2-D simulators commonly used in device analysis. The result is compared to the commonly used limiting form for both large and small values of the normalized barrier height. 9 refs.

Henning, Albert K. (Stanford Univ, CA, USA); Plummer, James D. *IEEE Trans Electron Devices* v ED-34 n 10 Oct 1987 p 2211-2212.

#### Simulation

**096418 TWO-DIMENSIONAL SHORT CHANNEL MOSFET STEADY STATE AND SUBSTRATE CURRENT SIMULATION.** Using total quantity of carrier analysis method, a new numerical model for two-dimensional short channel steady state MOSFET is presented. The Poisson equation, the continuity equations for electrons and holes are solved via two-dimensional MOSFETs simulator LADES1-A (Lishan Advance Device Simulation Version no. 1-A). The LADES1-A can be used to design and predict the effect of different process conditions and geometric structures of the devices. This simulator is very useful for device designer to study the phenomena inside the device aiming at decreasing the short channel effect by the optimum method. In order to illustrate the application of the simulator, some of our simulation results of short channel MOSFET are presented. The substrate current produced by hot carriers and the generation-recombination rate of nonequilibrium carriers are discussed in detail. (Author abstract) 11 refs. In Chinese.

#### Spectroscopic Analysis

**096419 LOW FREQUENCY NOISE AND DLTS AS SEMICONDUCTOR DEVICE CHARACTERIZATION TOOLS.** The technique of low-frequency noise vs temperature measurements is shown to be a powerful diagnostic technique for determining Generation Recombination (GR) trapping parameters in MOSFETs. From computer controlled measurements of low frequency noise vs temperature, the trapping parameters are extracted in a manner similar to that of Deep Level Transient Spectroscopy (DLTS). The trapping parameters are also extracted by curve fitting of the low frequency noise vs temperature curves. These noise-determined trapping parameters are compared with those measured by DLTS. The agreement between parameters determined by the spot frequency noise Arrhenius plot with those determined by DLTS is close, while the agreement between those determined by noise curve fitting is reasonable for noise peaks near room temperature, but becomes poor for low temperature noise peaks. By the use of PECVD silicon nitride as a passivation material, the sensitivity to measure GR traps by the low frequency noise vs temperature technique can be increased. (Edited author abstract) 7 refs.

#### Stability

**096420 INCOMPATIBILITY OF REQUIREMENTS FOR OPTIMIZING SHORT CHANNEL BEHAVIOUR AND LONG TERM STABILITY IN MOSFETS.** An analytical approach is presented which predicts that the requirements for minimizing short channel effects and long term degradation due to hot carrier trapping lead to incompatible requirements on the design of short channel MOSFETs. Model predictions are compared with experimental data and with the results of 2-D simulations. An asymmetrical MOSFET structure is proposed to circumvent this design problem. (Author

abstract) 14 refs.

## Switching

**096421 HIGH FREQUENCY SWITCHING OF POWER MOSFETS.** A great deal of attention has focused on optimizing the switching performance of the power MOSFET. Recent developments in the use of distributed power conditioning for logic circuits, pulse power applications and high frequency power conversion have resulted in an increase in switching frequencies. A series of tests on a 'topless' power MOSFET investigate high frequency switching performance, in particular the effect of source terminal parasitic inductance. (Edited author abstract) 5 refs.

**096423 ADVANCED 50-V HIGH-SIDE SWITCH TECHNOLOGY.** The advanced high-side switch (AHSS) technology integrates a high-density 50-V DMOSFET as a power switch and 5-V dense CMOS for digital ICs and up to 50-V CMOS output drivers. The 50-V DMOSFET has half the specific on-resistance of commercially available devices due to aggressive cell design and short channel approach. With this technology 3 million cell/sq in DMOSFET has also been demonstrated. The high-voltage CMOS utilizes a special lightly doped drain (LDD) structure. The doping profile and geometry layout of this LDD region has been highly optimized through field simulation and intensive experiments. The peak electric field under and around the gate oxide was drastically reduced to enhance gate strength and reliability. Study and attention were also paid to the layout and doping profiles to expand the CMOS safe operating area without running into latching problem before exceeding the rated blocking voltage, even at high temperature (150°C). By taking advantage of various diffusions associated with the DMOSFET, this complicated but high-performance AHSS was able to be realized through only 10 mask steps. The nature of this process allows the low-voltage CMOS portion to be shrinkable without changing the process. 3 refs.

## Theory

**096424 SUBSTRATE BIAS DEPENDENCE OF SHORT-CHANNEL MOSFET THRESHOLD VOLTAGE - A NOVEL APPROACH.** A simple theory to predict the threshold voltage variation of short-channel MOS transistors with substrate bias is proposed. While the basis of the model is vertical field perturbations due to the source-drain, its uniqueness depends on a definition of threshold voltage based on the amount of total free charge in the channel rather than inversion of the entire channel. The theory has been verified for transistors of three channel lengths, namely, 2.70, 1.70, and 0.70  $\mu\text{m}$ , fabricated with a p-well CMOS process. A comparison is made with an earlier model based on field perturbation. The

validity of the arguments underlying the theory has been demonstrated by 2-D device simulations with MINIMOS. 16 refs.

**096425 HOT-ELECTRON EFFECTS ON SHORT-CHANNEL MOSFET'S DETERMINED BY THE PIEZORESISTANCE EFFECT.** The piezoresistance effect of n-inversion layers in the hot-electron regime is discussed. The measurements were performed on short-channel n-MOSFETs at both 77 and 300 K. From the data at 77 K, clear evidence is obtained for different saturation velocities of electrons in Si depending on the occupation of the subbands. By application of this effect to 300 K, good agreement between theory and experiment is achieved. Furthermore, the mechanical prestress inside the transistor has been estimated to reach values of up to 150 N/mm<sup>2</sup>. 14 refs.

## Thin Films

**096426 THIN-FILM, ACCUMULATION-MODE p-CHANNEL SOI MOSFETS.** Electrical characteristics of thin-film (100 nm), accumulation-mode SOI p-channel MOSFETs are reported and compared to simulation. In the OFF regime, the p-type channel is fully depleted. As a result, low values of leakage current are obtained. Good threshold voltage control is obtained. (Author abstract) 5 refs.

Coline, J.P. (Hewlett Packard Ct R&D, Palo Alto, CA, USA). *Electron Lett* v 24 n 5 Mar 3 1988 p 257-258.

**096427 GATE COUPLING AND FLOATING-BODY EFFECTS IN THIN-FILM SOI MOSFETS.** Thin-film, silicon-on-insulator (SOI) MOSFETs exhibit bias-dependent suppression of the kink effect. For zero or positive back gate bias, the kink effect is suppressed but the threshold reports depends strongly on back gate bias. For sufficiently negative back gate bias (as might be the for total-dose radiation-hard applications), the kink effect re-emerges and the threshold voltage depends instead on the applied drain voltage. (Edited author abstract) 9 refs.

Tsao, S.S. (Sandia Natl Lab, Albuquerque, NM, USA); Myers, D.R.; Eller, G.K. *Electron Lett* v 24 n 4 Feb 18 1988 p 238-239.

**096428 SOME PROPERTIES OF THIN-FILM SOI MOSFETS.** The properties that can be expected from thin-film silicon-on-insulator transistors are described. Simple qualitative modeling shows that improvements of different parameters, such as subthreshold slope, hot-electron effects, and short-channel effects, can be obtained when thin, fully depleted films are used. The potential advantages of using these devices for future small-geometry CMOS applications are highlighted. 11 refs.

Coline, Jean-Pierre (Hewlett Packard Lab, Palo Alto, CA, USA). *IEEE Circuits Devices Mag* v 3 n 6 Nov 1987 p 16-20.

**096429 INVERSION-MODE MOSFET'S IN POLY-CRYSTALLINE SILICON THIN FILMS: CHARACTERIZATION AND MODELING.** The performance of MOSFETs in LPCVD (liquid-phase chemical vapor deposited) polysilicon is characterized. Specifically, the transistor I-V behavior, transconductance, channel mobility, and leakage current are discussed in detail. These observed device characteristics are quantitatively analyzed, based on a polysilicon MOSFET theory that is presented. The model utilizes the concept of the effective doping level and is analytic, tractable, and analogous to conventional bulk silicon MOSFET theory. Additionally, the adverse role of the grain boundary for device performance and the effect of grain-boundary hydrogenation in increasing the ON/OFF current ratio are described. 24 refs.

**096430 REDUCTION OF KINK EFFECT IN THIN-FILM SOI MOSFET'S.** Numerical simulation is used to show that potential and electric field distribution within thin, fully depleted SOI devices is quite different from that observed within thicker, partially depleted devices. Reduction of drain electric field and of source potential barrier brings about a dramatic decrease of kink effect. 7 refs.

Coline, Jean-Pierre (Hewlett-Packard Co, Palo Alto, CA, USA). *IEEE Electron Device Lett* v 9 n 2 Feb 1988 p 97-99.

## Transport Properties

**096431 ELECTRON VELOCITY OVERSHOOT AT ROOM AND LIQUID NITROGEN TEMPERATURES IN SILICON INVERSION LAYERS.** Effective electron velocities in silicon MOSFETs exceeding the bulk saturation values of  $10^7$  cm/s at room temperature and  $1.3 \times 10^7$  cm/s at liquid-nitrogen temperature are inferred. This conclusion suggests that electron velocity overshoot occurs over a large portion of the device channel length. To infer this phenomenon, submicrometer-channel-length Si MOSFETs with lightly doped inversion layers were fabricated. These devices have low field mobility of 450 cm<sup>2</sup>/V-s and showed only slight short-channel effects. Effective carrier velocities are calculated from the saturated transconductance  $g_m$  at  $V_{DS} = 1.5$  V after correction for parasitic resistances of source and drain. 11 refs.

**096432 INVESTIGATION AND MODELING THE SURFACE MOBILITY OF MOSFET'S FROM -25 TO +150°C.** The surface mobility of n- and p-channel MOS transistors with varying densities of oxide charge and interface states has been investigated at low drain voltage in the temperature range from -25 to 150°C. Mobility values were extracted from DC transfer characteristics using the Pao-Sah drain current model and taking into account interface-state charge and short-channel effects. The dependence of the surface mobility is calculated using a partly diffuse scattering model. The influence of oxide and interface state charges on current transport is modeled by screened Coulomb potential scattering and by surface potential fluctuation, which saturates for charge densities larger than  $6.25 \times 10^{10}$  cm<sup>-2</sup>. 30 refs.

**096436 ADVANCED SCHOTTKY TTL PROCESS EXTENDED.** Fast is a family of TTL circuits, manufactured using the Isoplanar process. They are designed to offer the switching speed and output drive capability of Schottky TTL, with superior noise margins and only one-fourth the power consumption. There are now 120 FAST device types. The latest development is FAST LSI. This extension of the process allows for higher density, higher performance functions. The article is a short review of the FAST family products.

Pusey, Ernie (Fairchild). *New Electron* v 20 n 4 Feb 17 1987 p 40.

**096437 ANOMALOUS BEHAVIOUR IN THE CAPACITANCE OF SELENIUM SCHOTTKY DIODES.** Measurements on Se-Tl, Se-Bi, and Se-Au Schottky diodes, fabricated by evaporation of thallium, bismuth, or gold respectively, on a layer of crystallized selenium have shown an anomalous minimum of incremental capacitance with variation of applied voltage at a frequency below about 1 kHz. The voltage of the minimum varies consistently with the estimated barrier height of the junctions and suggests that it arises from a deep level located some 0.4 eV above the valence band of trigonal selenium. The disappearance of the effect with increasing frequency, while qualitatively consistent with this interpretation, indicates the level to be at 0.6 eV. (Author abstract) 9 refs.

Champness, C.H. (McGill Univ, Montreal, Que, Can); Pan, J. *Can J Phys* v 66 n 2 Feb 1988 p 168-174.

**096438 REDUCTION OF SCHOTTKY BARRIER HEIGHTS BY SURFACE OXIDATION OF GaAs AND ITS INFLUENCE ON DLTS SIGNALS FOR THE MIDGAP LEVEL EL2.** The barrier heights of Al-Schottky diodes formed on surface oxidized GaAs have been found to be smaller than those on as-etched GaAs. They recovered to the as-etched value when the samples were annealed, probably due to reduction of the surface oxide layer by Al. The barrier height of Au-Schottky diodes formed on surface oxidized GaAs depend on the oxidation conditions. These variations of the barrier height can be explained by differences of the oxide compositions and bonding strengths of the metal oxides (Al<sub>2</sub>O<sub>3</sub>, Ga<sub>2</sub>O<sub>3</sub> etc.). In accordance with decrease of the barrier height, the DLTS (Deep Level Transient Spectroscopy) signal of the midgap level EL2 decreased and the signal peak shifted to a lower temperature even for

the Au-GaAs Schottky barrier. The decrease of the DLTS signal can be explained by a change of the occupation factor due to change of the reverse saturation current density. (Author abstract) 14 refs.

**096441 GaAs SCHOTTKY DIODE'S LATERAL SURFACE POTENTIAL DISTRIBUTION.** A high resolution scanning Auger microprobe was used to determine the potential on the GaAs surface as a function of the lateral distance from the Schottky electrode edge. The voltage varies nearly linearly with distance. For a hard breakdown case, the surface field is approximately 1.2E5 V/cm, similar to that in a computer simulated JTE case with bound charges approximately 1.2E12 cm<sup>-2</sup> extending laterally to twice the space charge layer thickness. For a leaky junction, the surface field is in 1E4 V/cm range, with small variations as a function of the current, similar to a SIPOS case. (Author abstract) 7 refs.

**096442 ELECTRICAL AND PHOTOVOLTAIC PROPERTIES OF Au/n-CuInSe<sub>2</sub> SCHOTTKY BARRIER DIODES.** The results of electrical and photovoltaic measurements taken with Au/n-CuInSe<sub>2</sub> contacts are presented and discussed. The electron conductivity of the samples was about 10<sup>-1</sup> Ω<sup>-1</sup> cm<sup>-1</sup>, and the electron mobility was 260 cm<sup>2</sup>V<sup>-1</sup> s<sup>-1</sup> at room temperature. The rectifying Au and the ohmic In contacts were prepared by vacuum evaporation on the opposite surfaces of the n-CuInSe<sub>2</sub> plate. The dark and light current-voltage characteristics at T = 298 K are shown. 14 Refs.

**096443 BORON IMPLANTATION EFFECTS ON Au-GaAs SCHOTTKY BARRIER.** In this work, we analyse the use of boron implantation in order to change the barrier height of GaAs Schottky contacts. The dependence on the annealing temperature and implantation dose of the barrier height variation, as well as of the diode quality factor are also reported. In both cases, the observed behavior is related to the presence of defects created by implantation in the surface layer, and their annealing kinetics. (Author abstract) 12 refs.

**096444 GaAs SCHOTTKY DEVICES FOR SUB-MILLIMETER WAVELENGTHS.** The objective of this paper is to determine the extent of Schottky barrier diode operation as a mixer element at submillimeter wavelengths. To this end, the most recent theoretical treatments are surveyed in order to determine: (a) the maximum frequency of device operation from basic physical principles, (b) intrinsic conversion loss limitations to the minimum anode size, (c) total conversion loss limits, and (d) projected mixer noise temperature values as a function of specific device parameters. The equivalent circuit considered throughout this analysis is presented. Minimum conversion loss in the THz range occurs for mixer diode with the smallest possible junction capacitance. This capacitance can be reduced along with the R<sub>s</sub>, C<sub>j</sub>(0) product by decreasing the device area and increasing the active layer impurity concentration. It is concluded on the basis of the four analyses of device mixer noise temperature and conversion loss that reasonable Schottky barrier mixer diode operation can be expected to at least 10 THz. 12 refs.

## Analysis

**096445 PHOTOEMISSION SPECTROSCOPY STUDIES OF Cu-GaAs (110) INTERFACE USING SYNCHROTRON RADIATION.** The Cu-GaAs (110) interface and Schottky barrier formation have been studied with synchrotron radiation photoemission spectroscopy for Cu overlayers deposited at room temperature. The evolution of the Ga3d and As3d spectra shows that strong interactions occur between Cu and GaAs substrate during the interface formation. For less than 0.5 monolayer (ML) Cu only rigid band bending was observed, but no interfacial reaction could be appreciated; for Cu more than 1 ML apparent interfacial reaction appeared, by which metallic Ga formed at the interface, and some As segregated on the metal; there were evidences of clustering or island growth of the Cu overlayers observed. Using deconvolution technique it has been found that the interfacial Fermi level lies at about 0.9 eV below the conduction band maximum. The mechanism of the Cu-GaAs (110) interface and Schottky barrier formation is discussed. (Author abstract) 19 refs. In Chinese.

## Contacts

**096446 CHARACTERISTICS OF WSi<sub>x</sub> FILMS AND ITS CONTACT TO GaAs.** The resistances and stresses of MSi<sub>x</sub> and WSi<sub>x</sub>/n-GaAs Schottky contacts using rf sputtered films with a variety of compositions have been investigated before and after annealing. Experimental results show that the characteristics of the films and Schottky contacts depend significantly on X. When X=0.62, WSi<sub>0.62</sub>/n-GaAs Schottky contact exhibits a high temperature stability after annealing at 800°C. (φ<sub>B</sub>=0.8 eV, n=1.1). A self-aligned GaAs MESFET has been fabricated using rf sputtered WSi<sub>x</sub>-gate. (Author abstract). 7 Refs. In Chinese.

## Electric Properties

**096447 SCHOTTKY DIODES WITH HIGH SERIES RESISTANCE: A SIMPLE METHOD OF DETERMINING THE BARRIER HEIGHTS.** The forward I-V characteristic of a Schottky diode is strongly affected by the series resistance. At low barriers and high resistances it is difficult to determine the diode param-

ters. I-V measurements at extremely low voltages enable the barrier height to be derived. In the case of indium tin oxide or palladium on a-Si:H, consistent results were obtained. (Author abstract) 18 refs.

**096448 INTERPRETATION OF NON-LINEAR SCHOTTKY BARRIER  $C^{-2}$ -V CHARACTERISTICS.** An analysis has been made of the non-linear  $C^{-2}$ -V characteristics exhibited by n-CdTe Schottky barriers. The empirical data are shown to be explained satisfactorily assuming the existence of deep traps at 0.8 eV below the conduction band. The shallow donor concentration inferred from this analysis is close to that calculated by a simpler method which treats the real junction as an equivalent ideal Schottky diode in parallel with a voltage independent capacitance. The latter procedure is shown to be invalid in this instance and an explanation is given for its apparent success. (Author abstract) 8 refs.

**096449 STUDY OF THE ELECTRICAL AND INTERFACIAL PROPERTIES OF SPUTTERED Ti/Si AND SPUTTERED  $TiSi_2$ /Si SCHOTTKY BARRIERS.** Schottky diodes were made by sputtering of Ti or  $TiSi_2$  on a hot Si substrate at a temperature  $T_s$  between room temperature and 760°C. For the  $TiSi_2$  sputtered samples I-V characteristics were obtained, which could be attributed to the abrupt metal-semiconductor interface (confirmed by Auger measurements). Due to the unreactive nature of the  $TiSi_2$  the native  $SiO_x$  layer is not converted. Therefore the barrier height  $\Phi_B$  hardly depends on  $T_s$  and is always larger than the corresponding  $TiSi_2$ /Si value. We also found that sputter deposition of Ti and  $TiSi_2$  creates donor-type defects into the Si substrate with concentrations depending on surface pretreatment, sputter power and substrate temperature. Most of these defects could be annealed at 200°C. For the sputtered Ti/Si diodes the sputter-induced defects together with the conversion of the native  $SiO_x$  layer (by Ti into  $TiO_x$  and  $Ti_2Si_3$ ) determines the  $\Phi_B$ - $T_s$  behavior. For  $T_s > 550^\circ\text{C}$  a  $\Phi_B$  value typical for a titanium disilicide/Si contact was measured. (Author abstract) 21 refs.

**096450 CHARGE TRANSPORT STUDY IN THIN FILM Au-CdTe SCHOTTKY DIODES.** Au-CdTe diodes were prepared on CdTe thin layers deposited electrochemically. Measurements of dark I-V characteristics at several temperatures and C-U characteristics at room temperature in darkness were used for the study of charge transport in the diodes. The results can be explained by a model consisting of the series connection of an Au-CdTe Schottky barrier, several intergranular (IG) barriers in the CdTe layer, and a relatively small series resistance of bulk of the grains. Some parameters of transport such as the quality factor of the diode and barrier heights of Schottky, and IG barriers are obtained and the impurity concentration and number of grain boundaries are estimated by comparison of theory with experiment. (Author abstract) 5 refs.

**096451 INTERFACE ANALYSIS AND ELECTRIC CHARACTERISTICS OF PALLADIUM SILICIDE-P-TYPE SILICON SCHOTTKY BARRIER DIODE.** The interface property of palladium silicide-silicon (P-type) Schottky Barrier Diode (SBD) has been studied by AES spectrum and EBIC image. The thickness of  $Pd_xSi_y$  layer and the deepness of schottky 'junction' are estimated. At room temperature, the response time ( $< 1\text{ns}$ ) of SBD to 1.06  $\mu\text{m}$  laser is roughly read out from

an oscillograph. By using DLTS, the position of the deep level in SBD surface space charge region  $E_T - E_v = 0.33\text{ eV}$ , the capture cross section  $\sigma_p$  ( $248\text{ K}$ )  $= 4.4 \times 10^{-18}\text{ cm}^2$  and the average impurity concentration of deep level  $N_T = 0.085(N_A - N_D)$  are made out. A 'lagging edge' of the pulsed response to laser resulting from the deep level is discussed. (Author abstract) 2 refs. In Chinese.

**096452 ELECTRICAL CHARACTERIZATION OF SCHOTTKY DIODES ON VERY LOW ENERGY ION-ETCHED GaAs SURFACES.** A study of the electrical behavior of Al and Au-GaAs Schottky diodes on ion-etched n- and p-type material in the energy range 0-200 eV is reported. The main results are: (i) the Schottky barrier height deduced from I-V characteristics decreases on n-type and increases on p-type material as the ion energy increases. (ii) The barrier becomes independent of the nature of the metal. (iii) The recovery of the initial barrier height by thermal annealing is more imperfect as the ion energy increases. (iv) A 50 eV ion etching followed by a 400°C annealing step is a good way to obtain quasi-ideal diodes. (v) Unlike previous explanations attributing electrical degradations of Schottky diodes on ion-etched semiconductors to the creation of donor-like defects, the observation of the C-V results shows that, in this low energy range, acceptor-like defect levels must be taken into account. (Edited author abstract). 38 refs.

**096453 DEPENDENCE OF PtSi SCHOTTKY DIODE ELECTRICAL BEHAVIOUR ON THE PLATINUM FILM THICKNESS AND ON THE ANNEALING PROCESS.** The current-voltage characteristics were measured in Schottky diodes prepared by the deposition of 30 and 60 nm platinum films onto Si  $< 111 >$  wafers and annealing of 520°C for 1/2 h. The current density in the thin platinum diodes is nearly an order of magnitude higher than that in the thick platinum diodes. In the former the current density also increases with increasing perimeter-to-area ratio. This behavior has been associated with the formation of a narrow cylindrical silicidic region penetrating inside the silicon substrates deeper than that flat internal interface and caused by the vertical diffusion of platinum at the  $SiO_2$  sidewalls. The experimental I-V characteristics are fitted by accounting for the effects of the deep silicidic both on the tunnelling contribution and on the lowering of the Schottky barrier height. (Author abstract). 22 Refs.

**096454 NEW RICHARDSON PLOT FOR NON-IDEAL SCHOTTKY DIODES.** The influence of operating temperature on the I-V and C-V characteristics of Al/n-GaAs Schottky diodes was studied. Diode parameters such as the ideality factor n and barrier height  $\Phi_{Ba}$  were found to be dependent on the temperature. For these diodes the usual Richardson plot  $\log(I_s/ST^2)$  as well as the modified plot  $I_s/ST^2$  vs.  $1/n(T)$  did not yield the true value for the effective Richardson constant  $A^*$  and barrier height  $\Phi_{Ba}$ . A new Richardson plot  $n(T)\log(I_s/ST^2)$  vs.  $1/T$  presented here results in a better estimation of  $A^*$  and  $\Phi_{Ba}$ . (Author abstract). 18 Refs.

## Electronic Properties

**096455 SPECTROSCOPY OF DELAYED ELECTRONIC TRANSITIONS IN GaAs SCHOTTKY DIODES.** Dielectric spectroscopy of semiconductors (DSS) reveals in frequency spectra of delayed electronic transitions in semi-insulating systems and it may be used to study the trapping/de-trapping processes in the space charge regions of Schottky diodes and at the metal-semi-

conductor interfaces. We report measurements for two types of diodes with different bulk doping, in the frequency range 0.01 Hz to 10 kHz, with the temperature and bias as variable parameters. The trapping processes in the space charge region are shown to have non-exponential time dependence, and the interfacial processes give strong deviations from the classically expected behavior at very low frequencies and high temperatures, with a strong dependence on external bias. Certain phenomena appear to point to many-body interactions having a role in determining the rate processes in these Schottky diodes. (Author abstract) 18 refs.

## Impurities

**096456 INVESTIGATION OF DEEP IMPURITIES IN SCHOTTKY DIODES ON HIGH-RESISTIVITY SILICON.** It is shown that in a Schottky Au-Si diode formed on high-resistivity n-type silicon the quasi-Fermi levels are not flat in the greater part of the space charge region. A procedure is given to determine the parameters of the space charge distribution and the energy levels of deep impurities from C-U and C-f characteristics. A model with a single deep impurity level and with uniform distribution of shallow and deep impurity concentrations is assumed. The method is demonstrated for an Au-Si diode used as a nuclear radiation detector. 14 refs.

Dabrowski, W. (Univ of Mining & Metallurgy, Cracow, Pol). *Phys Status Solidi A* v 105 n 2 Feb 1988 p 511-520.

**096457 CHARACTERIZATION OF ENHANCED BARRIER SCHOTTKY DIODES IMPURITY PROFILING IN THE PUNCH-THROUGH REGION.** We have established a theoretical basis for impurity profiling of the punch-through p-layer in metal-p<sup>+</sup>-n structures and have successfully applied this to Au/n-GaAs enhanced barrier diodes having a shallow Be implant under the metal. The theory uses the thermionic emission model for electron conduction over the barrier. Use of our model to interpret Schottky diode current-voltage characteristics and capacitance-voltage data yields the spatial dependence of the activated Be implant. Normal capacitance-voltage analysis can profile only part of the n-region and not the p-region in punch-through. Our results scale with the SIMS profile of the annealed 5 keV Be implant. (Edited author abstract) 12 refs.

## Junctions

**096458 ANALYSIS OF THE PHOTOCURRENT INDUCED IN A SEMI-INFINITE SCHOTTKY BARRIER BY A TIME VARYING FOCUSED LASER BEAM.** General expressions are derived for the photocurrent induced in a semi-infinite Schottky barrier diode due to excitation by a focussed convergent light beam. A simple repeated transform technique using the Hankel and Laplace transformations is used to solve the diffusion equation. Special cases are considered where the excitation can be described by  $\delta$  functions, step functions, and harmonic modulation of the beam. The effects of beam focusing and cases where a simpler treatment may be used are discussed. (Author abstract) 15 refs.

**096459**  $n$ - $V_{oc}$  DIAGRAM AND THE PHYSICS OF NATIVE INTERFACIAL LAYER OF THE SCHOTTKY BARRIER. A method of investigating an interface of the Schottky barrier by a photovoltaic effect is examined in a complex analysis of the interfacial layer effects in Cu/Cu<sub>2</sub>O junctions. This approach assumes construction of the  $n$ - $V_{oc}$  (nonideality factor vs open circuit voltage) diagram for the devices studied and its analysis in terms of theoretical model of the tunnel MIS Schottky diode. Two interesting cases from a tutorial viewpoint are considered: the case of native interfacial layer (A) and that of intentionally modified native interfacial layer (B). (Edited author abstract) 12 refs.

Iwanowski, R.J. (Polish Acad of Sciences, Warsaw, Pol). *Phys Scr* v 37 n 5 May 1988 p 790-794.

**096460** NEW METHOD FOR MEASURING CARRIER CONCENTRATION PROFILE NEAR A GAAS SURFACE THROUGH A NETWORK ANALYZER. A method based on S-parameter measurement which precisely obtains the junction capacitance of the Schottky gate of GaAs MESFETs is proposed. In this method, the junction capacitance is derived from a diode circuit simulation based on S-parameter measurements. Determination of the junction capacitance under forward-biased voltage and the carrier concentration profile near the channel surface of Schottky gates are possible with this method. 4 refs.

## Mathematical Models

**096461** PHYSICAL EQUIVALENT CIRCUIT MODEL FOR PLANAR SCHOTTKY VARACTOR DIODE. A physical equivalent circuit model for the planar GaAs Schottky varactor diode is presented. The model takes into account the distributed resistance and capacitance of the active layer, the sidewall capacitance, and the parasitic resistances and accurately accounts for the high series resistance observed near the pinch-off voltage. The dependence of the maximum series resistance of varactor size, frequency, and doping profile has been theoretically investigated, and the results agree well with experimental data. The proposed model can be easily used for optimization of planar Schottky varactor diodes with regard to broad-band monolithic VCO constraints. 4 refs.

**096464** ON THE FORMATION OF NEAR IDEAL QUASI-SCHOTTKY BARRIERS BETWEEN INDIUM TIN OXIDE AND GALLIUM ARSENIDE. The formation of good quality diodes between indium tin oxide and gallium arsenide is explained in terms of existing metal-semiconductor theory. A characterization of the devices using capacitance-voltage and current-voltage techniques is presented. Diodes have demonstrated near-ideal behavior with ideality factors of less than 1.02 and barrier heights of  $(0.85 \pm 0.05)$  eV, suggesting the formation of a quasi-Schottky barrier, the height of which is pinned by surface-state effects. (Author abstract) 22 refs.

Parker, D.G. *GEC J Res* v 5 n 2 1987 p 116-123.

## Processing

**096465** EFFECT OF SCANNING ELECTRON BEAM ANNEALING ON THE REVERSE CURRENT IN Ti-GaAs SCHOTTKY DIODES. The effects of scanning electron beam annealing of Ti-GaAs Schottky diodes on the reverse diode characteristics are observed and discussed. Significant reductions in the values of the saturation current, the generation current and the shunt current are attributed to the low-energy secondary excitations generated by electron bombardment. (Author abstract) 11 refs.

## Spectroscopic Analysis

**096467** DIELECTRIC SPECTROSCOPY OF SILICON BARRIER DEVICES. Dielectric studies, equivalent in many respects to the familiar admittance spectroscopy, are reported on three silicon barrier devices: a Schottky diode on 10 $\Omega$ cm n-type (A), a surface barrier diode on 10 $\Omega$ cm n-type (B) and an n<sup>+</sup>-p junction on 3  $\times$  10 $\Omega$ cm material (C). The response in the frequency range 0.01-10 $\Omega$ Hz and in the temperature range 10-325 K

shows three principal features in A and B: the d.c. conductance, a strongly dispersive behaviour at low frequencies and high temperatures, a secondary loss peak associated with the d.c. conduction, and a high-frequency loss peak which is distinctly broader than Debye. The dispersive process which is known as Low-Frequency Dispersion (LFD) and which may go over into negative capacitance under forward bias, is seen only in interfacial devices. The n<sup>+</sup>-p junction shows only the d.c. process and the high-frequency loss peak which is almost Debye-like. Several of these features have been seen previously in other devices, especially LFD in GaAs and it is significant that they are now seen in silicon barrier devices implying that they are not simply a consequence of the compound nature of the material. They are related to the presence of electrochemical interaction in the oxide layer under the metal contact. (Author abstract) 23 refs.

## Surfaces

**096468** EFFECT OF STRUCTURE TREATMENT ON Al-Si SCHOTTKY STRUCTURE. There is no unique theory to explain the anomalies in the theoretical and experimental I-V characteristics. The formation of the surface space charge region and the bending of the energy bands at the semiconductor surface for a given surface treatment is complex. This introduces uncertainties in the barrier height ( $\phi_B$ ) and ideality factor ( $\eta$ ) in a Schottky diode. In the present note the effect of different surface treatments and the annealing temperature on the  $\phi_B$  and  $\eta$  values of Al-Si Schottky diodes is studied. 9 refs.

Vava, P.R. (Indian Inst of Technology, Madras, India); Majhi, J. *Phys Status Solidi A* v 106 n 2 Apr 1988 p k209-k213.

## Temperature Effect

**096469** TEMPERATURE DEPENDENCE OF BARRIER HEIGHTS OF Au/ $n$ -CdTe SCHOTTKY DIODES. The temperature dependence of the barrier heights of Au/ $n$ -CdTe Schottky diodes has been investigated by measuring the I-V characteristics at different temperatures. The results show that the apparent barrier heights increase linearly with increasing temperature and a rising rate of  $9 \times 10^{-4}$  eV/K is obtained. These results agree with those of K. Hattori and others on InP. (Edited author abstract) 6 refs. In Chinese.

Zhang, Shibiao (Nankai Univ, Tianjin, China); Shi, Shangyu. *Bandaoti Xuebao* v 9 n 4 Jul 1988 p 443-445.

## Testing

**096470** STRUCTURAL NONUNIFORMITY OF EPITAXIAL GALLIUM ARSENIDE FILMS AND THE ELECTROPHYSICAL CHARACTERISTICS OF SCHOTTKY DIODES MADE FROM THEM. The current level of development in microelectronics is characterized by intensive research into the electrophysical properties of semiconductor devices fabricated from binary semiconductor compounds, namely gallium arsenide. However, gallium arsenide has not been widely used for devices that operate at high temperatures and power levels because of the high density of crystal lattice defects. The basic parameters of these devices largely depend on the uniformity of the structure and the impurity in the source material. It is also assumed that defects in the crystal construction and nonuniformity of the impurity compound in microvolumes of the device structure are responsible for the appearance of domains and current pinches. We will examine the principles of a new noncontact, nondestructive method for making electrically active defects visible and the features of surface and volume defects in epitaxial gallium arsenide films. 14 refs.

Theory See TRANSISTORS—Electric Properties.

## Thermal Effects

**096471 EFFECTS OF THERMAL SILICIDATION ON THE CURRENT TRANSPORT CHARACTERISTICS OF  $Ti / <111>Si$  SCHOTTKY-BARRIER CONTACTS.** Using the interfacial-layer theory we present a systematic study on the effects of thermal silicidation on the current transport characteristics of  $Ti-nSi$  and  $Ti-pSi$  Schottky-barrier contacts. Based on the developed theory, the experimentally observed deviations from ideal thermionic-emission I-V model can be interpreted by the progressive variations of typical parameters such as thermal-equilibrium barrier height  $\phi_{B0}$ ,  $\phi(\phi_{Bp}, \phi)$ , interfacial-layer capacitance per unit area ( $C_i$ ), diode ideality-factor ( $n$ ) at a certain forward-bias voltage, and interface-state-apparent-spectrum (ISAS) obtained by both I-V and constant-temperature-Schottky-capacitance-spectroscopy (CTSCS) methods. We found that associated with the formation of stoichiometric  $TiSi_2$  at the  $Ti/Si$  interface, there is a drastic change of barrier height as well as diode ideality-factor without a prominent degradation of the soft reverse I-V characteristics. The changes happened in the interface-state spectra can be further interpreted in terms of real interface-state density and effective minority-carrier to majority-carrier capture rate ratio of the interface states. 16 refs.

## Transients

**096472 TRANSIENT ANALYSIS OF SCHOTTKY-BARRIER DIODES.** The turnon and turnoff transients of a Schottky-barrier diode are determined by an analysis based on thermionic emission across the metal-semiconductor barrier and a displacement current within the space charge region. The results of the analysis are compared to those from a device simulator and are shown to be in excellent agreement. 10% time constants for both turnon and turnoff transients are shown to be strongly controlled by the SBDs depletion capacitance in reverse bias. (Author abstract) 8 refs.

## Transport Properties

**096473 CURRENT TRANSPORT MECHANISMS IN ATOMICALLY ABRUPT METAL-SEMICONDUCTOR INTERFACES.** A comprehensive model for electron transport mechanisms across a fully formed Schottky-barrier junction is proposed in which the metal-semiconductor interface is approximated as an abrupt quantum mechanical transition. Improved formulations of the barrier-lowering mechanisms and carrier tunneling effects are derived where the dipole barrier lowering is modeled as a single exponential decay of the total surface charge density. Quantum calculations follow a two-band model in which the imaginary component of the electron wave vector in the semiconductor energy gap is obtained by including the effect of both conduction and valence states. The energy band profile effects are included in the calculation of tunneling current, and it is shown that the finite negative charge residing at the metal-semiconductor interface considerably modulates the tunneling transmission probability of carriers. Experimental results obtained from atomically clean  $Al-n+GaAs-nGaAs$  interfaces fabricated by in situ molecular-beam epitaxy (MBE) are shown to be in excellent agreement with the transport calculations. 50 refs.

Shenai, Krishna (Stanford Univ, CA, USA); Dutton, Robert W. *IEEE Trans Electron Devices* v 35 n 4 Apr 1988 p 468-482.

**096474 HOT CARRIER TRANSPORT EFFECT IN SCHOTTKY-BARRIER DIODE GROWN BY MBE.** Hot-electron transport effects in Schottky-barrier diodes

grown by molecular-beam epitaxy (MBE) were investigated. Comparisons with experimental results for an  $Al-n+GaAs$  diode shows that terminal currents obtained using the Monte Carlo (MC) method agree well with experiment and are higher than those of conventional analysis for the forward-bias condition. A much higher thermionic-emission velocity at the Schottky contact was obtained using the MC analysis compared to previously published results. It is argued that these hot-electron transport effects should be included when analyzing device physics and current-voltage characteristics of Schottky-barrier diodes grown by MBE. 10 refs.

## SEMICONDUCTOR DEVICES, TRANSIT TIME See Also OSCILLATORS, SOLID STATE—Analysis.

### Mathematical Models

**096475 EFFICIENCY AND POWER OUTPUT OF THE QUANTUM-WELL INJECTION TRANSIT-TIME DEVICE.** A theoretical analysis is presented of the efficiency and power capability of the quantum-well injection transit-time (QWITT) device. When compared with traditional semiconductor sources such as TED (transferred-electron device) or IMPATT (impact avalanche and transit time) devices, the results show that the QWITT is a far better source at millimeter wavelengths. The superior performance of the QWITT is due to its high intrinsic frequency response time, as well as to the extremely localized carrier injection mechanism and the utilization of the high transient velocity of carriers at small distances. Computer simulations that took these effects into account clearly confirmed these merits. For example at 300 GHz, a single QWITT provides an output power of 1.2 mW at 7.4% efficiency when it is matched to a resonant circuit with about 1- $\Omega$  resistance. 9 refs.

**096476 SIGNAL, RECOMBINATION EFFECTS AND NOISE IN AMORPHOUS SILICON DETECTORS.** Some properties of hydrogenated amorphous silicon diodes are described. Back biased diodes of the Schottky, p-i-n type, in thicknesses ranging from 5-15  $\mu m$ , have been tested with 6 MeV alpha particles and with 1 and 2 MeV protons. Large signal saturation, due to electron-hole recombination, occurs for high LET particles. Diodes have been exposed to fast neutron fluences up to  $10^{13} cm^{-2}$  and shown to have better radiation resistance than similarly exposed crystalline silicon detec-

tors. From our measurements we extrapolate that minimum ionizing particles can be detected with stacked layers 100-120  $\mu m$  thick, with adequate signal/noise levels. (Author abstract) 13 refs.

**096477 DIFFUSION LENGTH MEASUREMENTS IN BULK AND EPITAXIALLY GROWN III-V SEMICONDUCTORS USING CHARGE COLLECTION MICROSCOPY.** Diffusion lengths and surface recombination velocities were measured in GaAs diodes and InP finished solar cell. The basic technique used was charge collection microscopy also known as electron beam induced current (EBIC). The normalized currents and distances from the pn junction were read directly from the calibrated curves obtained while using the line scan mode in an SEM. These values were then equated to integral and infinite series expressions resulting from the solution of the diffusion equation with both extended generation and point generation functions. (Edited author abstract) 5 refs.

**096479 DIODE AS AN ENERGY-CONTROLLED, NOT A CHARGE-CONTROLLED DEVICE.** The conventional notion of electricity as electrons jostling their way down a wire cannot, according to the author's theory be the thing that arrives at and controls the operation of a diode. His developing analysis of the behavior and of a diode is totally at odds with the traditional view, based on electrons, holes and energy barriers across the p-n interface.

Catt, Ivor. *Electron Wireless World* v 93 n 1619 Sep 1987 p 903-904.

**096480 P-N JUNCTION DIODE CAPABLE OF WORKING AT 650°C.** The National Institute's semiconductor has been made possible by growing large crystals of cubic boron nitride (c-BN), which has the same crystal structure as diamond and shows similarities in hardness and thermal conductivity. The Institute succeeded not only in making c-BN, p and n semiconductors but also in producing a c-BN junction diode. The junction diode was successfully shown to operate at a high temperature of 650°C. The diode manufacturing process is described.

Anon. *JEE J Electron Eng* v 25 n 253 Jan 1988 p 77-79.

**096481 SURFACE-MOUNT P-I-N DIODES OPERATE BEYOND 2GHz.** Until recently, p-i-n diode switches with good performance beyond the few hundred of megahertz range have been difficult and expensive to manufacture. With the introduction of triple p-i-n diodes in a surface-mount package, Siemens claims to have overcome both these problems.

Anon. *Electron Wireless World* v 93 n 1622 Dec 1987 p 1261-1262.

**096482 BULK-BARRIER-DIODE.** Bulk-barrier-diodes (BB-diodes) are majority-carrier devices and can, therefore, be used up to frequencies in the microwave region. Similar to Schottky-barrier diodes, charge-carrier transportation is determined by an energy barrier. In Schottky-barrier diodes, charge-carrier transportation is determined by an energy barrier. In Schottky-barrier diodes the barrier is located at the metal/semiconductor boundary, whereas in BB-diodes it is found inside the semiconductor and is the result of a space-charge zone in a three-layered npn- or pnp-structure with a very thin base region. The height of the barrier is determined by technological parameters such as doping density and layer thickness. As the current in BB-diodes, just as in Schottky-barrier-diodes, is an exponential function of barrier height, the current-voltage-characteristic can be adjusted by technological means. BB-diodes can be used up to frequencies in the microwave region as rectifier for small voltages and as frequency mixer. BB-Diodes are very sensitive thermal and optical detectors from infrared until ultraviolet. (Author abstract) In German. 23 refs.

**096483 DOSE-VOLTAGE DEPENDENCE OF CO-AXIAL BREMSSTRAHLUNG DIODES.** The relations  $D \propto IV^{2.65}$  is widely used to estimate the on-axis radiation-dose rate for flash x-ray sources,  $D$ , as a function of diode current,  $I$ , and voltage,  $V$ , 1 m downstream of an optimized bremsstrahlung target. This relation is valid only for pencil beams. In this paper, we show that for diodes having beams with finite spatial and angular extent, this relation can still be used if the power 2.65 is modified. Using particle-in-cell and radiation-transport codes, this modification is evaluated for a diode proposed for the 20-MeV HERMES III accelerator that is currently under construction. (Edited author abstract). 21 refs.

**096485 COMPUTER SIMULATION OF THE JUNCTION FIELD IN DOUBLE MESA HIGH VOLTAGE DIODES.** In order to fabricate high breakdown voltage diodes, the junction field must be properly controlled. This paper deals with a new junction termination geometry which can reduce the surface field, and achieves a high breakdown voltage in the junction. The new method is called the double mesa etch method (DMEM). These devices yield a good high-voltage junction rectifying property. The fabrication processes developed in this study are believed to be important for fabricating high power devices for the future. (Edited author abstract) 12 refs.

**096486 EFFECTS OF INTERFACIAL STATES ON THE CAPACITANCE-VOLTAGE CHARACTERISTICS OF Pd/SiO<sub>2</sub>/n-Si SCHOTTKY DIODES.** The shape of the  $1/C^2$  vs reverse voltage characteristic of a MIS device, with an ultrathin insulating layer, was theoretically examined taking into account interface states effects. The model foresees a linear behavior with a lower slope with respect to the ideal MS curve if interface states in communication with the semiconductor are present.  $1/C^2$ -V curves of Pd/SiO<sub>2</sub>/n-Si MIS Schottky diodes were measured under nitrogen and in two hydrogen/nitrogen mixtures, and were compared with Pd/n-Si curves. Changes of slope and the appearance of nonlinear behavior observed in hydrogenated devices are interpreted in terms of interactions between hydrogen atoms and interface states. Pd-gate MIS structures were shown to be an interesting experimental system to observe the effects of interfacial states on the electrical properties of the SiO<sub>2</sub>/n-Si interface. **096488 CURRENT OSCILLATION RELATED TO N=3 SUBBAND LEVELS UP TO ROOM TEMPERATURE IN InGaAs/InAlAs MQW DIODES.** A clear current oscillation related to the  $n=3$  subband levels was observed up to room-temperature in the forward I-V characteristic of the InGaAs/InAlAs MQW diodes, as well as a current oscillation related to the  $n=2$  subband levels. A significant hysteresis characteristic was also observed for the current oscillation related to the  $n=3$  subband levels at 77 K. The energy difference between the  $n=1$  and  $n=2$  subband levels estimated from the I-V characteristic agrees with that obtained from the absorption spectrum. (Author abstract) 8 refs.

**096490 FIELD AND ELECTRON FIELD EMISSION CURRENT IN A DIODE WITH A SPHEROIDAL ANODE CHAMBER.** Various field-emission systems, in which the anode is a nearly closed surface with a small opening for the entry of the field-emission cathode (FEC), are now being investigated. A typical example of such a system is the FEC placed in a microwave resonator. An investigation of the dependence of the electric field

intensity  $E$  and the emission current  $I$  of such a diode on its geometrical parameters is of practical interest. No analytical methods exist for calculating  $E$  and  $I$  in such systems. The use of numerical methods is hampered by the fact that the dimensions of the typical geometrical parameters of the system differ by three to five orders of magnitude. A simple method is proposed for calculating  $E$  and  $I$  of a field-emission system in the static regime. 7 refs.

**096491 FORWARD CURRENT-VOLTAGE CHARACTERISTICS OF GALLIUM ARSENIDE POWER DIODES AT HIGH CURRENT DENSITIES.** The forward current-voltage characteristics of power gallium arsenide diodes were investigated at the current density range of  $j$  approximately  $10^{-10}$  A/cm<sup>2</sup>. The ratio  $w/L$  ( $w$  is the width of the undoped  $N_0$  base,  $L$  is the diffusion length) was varied in a wide range by irradiation of the p-n structures with  $\gamma$ -quants of 1.25 Mev energy. Experimental data were compared with theoretical calculations taking into account the reduction of p-n junction injection coefficients. It has been shown that experimental data fit well with the theory if saturation current density is approximately  $10^{-18}$ - $10^{-16}$  A/cm<sup>2</sup>. There is no necessity to consider the reabsorption of the radiative recombination (RRR) effect to explain the experimental results. Simple analytical expressions for the current-voltage characteristics of GaAs diodes are proposed for a wide range of  $j$ ,  $w$  and  $w/L$  values. (Author abstract) 14 refs.

**096492 SOME INTERESTING CHARACTERISTICS OF GaAs VERTICAL p<sup>+</sup>in<sup>+</sup> DIODES.** GaAs vertical p<sup>+</sup>in<sup>+</sup> diodes have been studied in the temperature range 187-373 K. The voltage and temperature dependence of the experimental results indicates that the transport mechanism is dominated by leakage in the low voltage and by high-injection diffusion in the high voltage regions. The temperature variation of the ambipolar diffusion length ( $L_i$ ) and the minority carrier lifetime ( $T$ ) has been evaluated and corresponding empirical relations have been obtained. A theoretical analysis gives  $T = 5$  ns at room temperature. (Author abstract). 11 refs.

Khan, W.I. (Univ of Leeds, Leeds, Engl). *Solid State Electron* v 31 n 8 Aug 1988 p 1265-1268.

**096493 SWITCHING MECHANISM IN THE HETEROSTRUCTURE HOT-ELECTRON DIODE.** In the heterostructure hot-electron diode (H<sup>2</sup>ED) two possible conduction mechanisms exist. At low fields, the current is limited by tunneling through a wide-bandgap heterostructure barrier, resulting in a relatively large device series resistance. At higher fields, electrons are heated to sufficient energies so that thermionic emission over the barrier becomes dominant and the series resistance in this region become negligible. Since the energy distribution of electrons is confined to a narrow range of energies, one or the other of these modes will dominate conduction. The transition between these current conduction modes is shown to result in a negative differential resistance (NDR) and switching speeds that may be extremely fast. Results of both theoretical and experimental investigations of the H<sup>2</sup>ED that verify the proposed mechanism and determine more precisely the underlying physical phenomena involved are presented. It is shown using an analytical theory that the field switching mechanism previously proposed is consistent with the NDR observed in the H<sup>2</sup>ED. In addition to the tunneling and

thermionic emission of hot electrons, the accumulation of electrons at the heterointerface is identified as an important mechanism in the operation of the device. 1 ref.

## Electronic Properties

**096494 HIGH-FIELD, NONLINEAR ELECTRON TRANSPORT IN LIGHTLY DOPED SCHOTTKY-BARRIER DIODES.** The high-field transport of electrons in an n-type Schottky barrier diode is analyzed in relation to the existing synthesis of drift-diffusion (DD) and thermionic emission (TE) theories. Energy relaxation is shown to play a significant role in allowing the DDTE theory to encompass as wide an applicability as it does in spite of its underlying assumptions. The transport equations for energy and momentum balance are solved for the electrostatic potential distribution of a Schottky diode while including quasi-ballistic effects of the inertia of the energy and momentum fluxes. Relaxation of both momentum and energy is included through scattering with ionized impurities, acoustic phonons and optical phonons. The model is applied to a silicon Schottky barrier and the results related to the existing theories. (Author abstract) 44 refs.

**096497 MONOLITHICALLY INTEGRATED LASER/PHOTODETECTOR.** The fabrication and performance characteristics of a laser structure with monolithically integrated monitoring photodiode are described. The structure utilizes semi-insulating Fe doped InP layers for confinement of the current to the active region of the laser and for the separation of the laser and the photodetector sections. The lasers have threshold currents in the range 30-40 mA and emit in a single frequency by virtue of frequency selective feedback, provided by a grating etched on the substrate. The photodetector provides approx. 300  $\mu\text{A}$  of photocurrent per mW of laser power which is comparable to the value for a large area Ge photodiode generally used to monitor laser power. The new structure

also minimizes the unwanted reflection effects on laser performance caused by light reflected from the photodiode interface. (Author abstract) 7 refs.

**096499 SHANNON CONTACT FORMATION ON GaAs WITH INTERFACIAL NITROGEN INCORPORATION.** The family of refractory metal nitrides (TiN, ZrN, NbN, and WN) exhibits enhanced rectifying barrier heights on n-GaAs after high-temperature annealing and the diodes have electrical characteristics of Shannon contacts (i.e., metal-p-n structure). A further enhancement of the barrier height can be achieved by implanting nitrogen into n-GaAs substrates with a negative substrate bias (up to  $-400 \text{ V}$ ) prior to sputter-deposition of TiN, ZrN, or  $\text{W}_5\text{Si}_3$  gates. After rapid thermal annealing at temperatures above  $700^\circ\text{C}$ , the I-V characteristics of the diodes follow the voltage dependence of the Shannon energy barrier  $\Phi_B(V)$  and a positive is developed after the onset of Shannon contact formation. A reduction of gate current (by more than four orders of magnitude) and a twofold reduction of diode capacitance can be obtained. Annealing between  $500$  and  $700^\circ\text{C}$  shows a vertical shift of the  $\Phi_B(V)$  curves, which indicates the reduction of interface states. With increasing nitrogen implantation energy, and hence the nitrogen penetration depth, the diode reverse breakdown voltage increases from  $-10$  to  $-18 \text{ V}$  and the breakdown characteristics changes from a 'soft' breakdown to avalanche breakdown. 1 ref.

## Heat Treatment

**096500 ANNEALING EFFECT ON Au/a-Si:H/a-Si:H(n-TYPE)/Cr SCHOTTKY DIODES PREPARED BY AN RF MAGNETRON SPUTTERING TECHNIQUE.** The annealing effect on Au/a-Si:H/a-Si:H(n-type)/Cr-type Schottky diodes has been investigated. Thin films of amorphous silicon were prepared by an RF magnetron sputtering technique on a glass substrate with Cr contacts and then gold electrodes (area =  $7.85 \times 10^{-3} \text{ cm}^2$ ) were fixed under a vacuum of  $10^{-5}$  Torr. Measured current-voltage characteristics, before and after annealing at about  $70-200^\circ\text{C}$ , show significant differences and therefore it has been concluded that the rectification ratio increases and the ideality factor decreases with increasing annealing temperature. The barrier height  $\phi_{Bn}$  and density of surface states  $D_s$  were found to be  $\phi_{Bn} = 0.641$  and  $0.726 \text{ eV}$  and  $D_s = 3.47 \times 10^{13}$  and  $3.30 \times 10^{13} \text{ states cm}^{-2} \text{ eV}^{-1}$  employing Crowell-Sze's and Cowley-Sze's theories respectively. The changes in the current-voltage characteristics were explained by means of surface states at the metal/semiconductor interface. (Author abstract) 28 refs.

**096501 CHARACTERISTICS OF THE HYDROGENATED AMORPHOUS SILICON-CRYSTALLINE CADMIUM TELLURIDE HETEROJUNCTION DIODE.** The current-voltage characteristics and visible and x-ray photocurrent characteristics have been investigated for a heterojunction diode constructed of plasma-deposited hydrogenated amorphous silicon (a-Si:H) and single crystal cadmium telluride (c-CdTe). Devices showed low reverse bias saturation current, a photoresponse spectrum ranging from approximately 400-800 nm and a 3-decade increase in reverse bias saturation current when exposed to 40 keV x-rays. (Author abstract) 8 refs.

Meikle, Scott G. (Shizuoka Univ, Hamamatsu, Jpn); Hatanaka, Yoshinori. *Jpn J Appl Phys Part 2* v 26 n 11 Nov 1987 p 1812-1814.

**096502 ISOTYPE  $\text{Al}_{0.05}\text{Ga}_{0.95}\text{As}/\text{Al}_{0.35}\text{Ga}_{0.65}\text{As}$  INTERFACE OF THE LPE-GROWN DOUBLE HETEROSTRUCTURE AT ELEVATED TEMPERATURE.** The isotype interface of a double heterostructure is studied by measuring the capacitance-voltage characteristic (C/V technique). For the LPE-grown  $\text{Al}_{0.05}\text{Ga}_{0.95}\text{As}/\text{Al}_{0.35}\text{Ga}_{0.65}\text{As}$  system it is shown that the effective barrier height of the p-type heteroboundary can be estimated even in the range below 25 meV by recording the C/V characteristic at lower than room temperature. Experimental evidence is given that the effective barrier height at the isotype p/p interface of the NpP-type heterostructure may be raised after treatment at elevated temperature. This reaction at the heteroboundary depends on the mechanical stress additionally introduced by the solder. The gradual increase in light output often observed in AlGaAs double heterostructure diodes during operation at elevated temperature can be approximated by a step-like function of the operation time and a characteristic delay time. The process is mainly thermally controlled with an activation energy of about 0.53 eV. A correspondence is found between the microscopic process at the p/p interface and the gradual increase in light output. It is suggested that the reaction at the isotype interface of LPE-grown AlGaAs heterojunctions is at least partly the origin of the increase in light output during operation at elevated temperature. Both phenomenon are not dependent on the operation current and are more effective at low external compressive stress. (Edited author abstract) 8 refs.

**096503 THEORETICAL AND EXPERIMENTAL INVESTIGATIONS OF THE HETEROSTRUCTURE HOT ELECTRON DIODE.** Experimental data are presented on the heterostructure hot electron diode ( $\text{H}^2\text{ED}$ ), a two-terminal device that exhibits S-shaped negative differential resistance due to a field dependent transition between the current conduction modes of tunneling and thermionic emission of hot electrons in a two-layer AlGaAs heterostructure. Results are presented on various single and multiple period  $\text{H}^2\text{ED}$  structures fabricated from wafers grown by metalorganic chemical vapor deposition (MOCVD). Preliminary microwave characterization of the  $\text{H}^2\text{ED}$  on non-optimized structures have resulted in test-fixture-limited oscillation at frequencies greater than 17 GHz. (Edited author abstract) 6 refs.

**096504 HIGH-TEMPERATURE CUBIC BORON NITRIDE P-N JUNCTION DIODE MADE AT HIGH PRESSURE.** A p-n junction diode of cubic boron nitride was made by growing an n-type crystal epitaxially on a p-type seed crystal at a pressure of 55 kilobars and a temperature of about 1700°C. A temperature-difference solvent method was used for the crystal growth, and beryllium and silicon were doped as acceptors and donors, respectively. Formation of the p-n junction was clearly confirmed at 1 bar by rectification characteristics and by existence of a space charge layer of the junction as observed by electron beam induced current measurement. This diode operated at 530°C. (Author abstract) 14 refs.

**096505 ROOTS AND RAMIFICATIONS OF A UNIFIED THEORY OF ELECTRICAL CONDUCTION IN p-n JUNCTIONS, HETEROJUNCTIONS, AND SOLAR CELLS.** Conduction in various types of p-n junctions, heterojunctions, and Schottky diodes, and in homojunction and heterojunction solar cells have been explained by numerous different theories, whose applicability often depends on current and temperature ranges and device material and junction type. This paper, however, reviews the results of a unified theory of dc conduction, which reflect all physical and geometric parameters of the device just described, and which accurately agree with extensive experimental data reported by some 27 authors over a period exceeding a quarter of a century. The underlying concepts of this general dc theory of diodes pertain to what may be called the thermodynamic formulation of generalized fields (TFGF). This paper reviews, as applied to diodes, some fundamental aspects of the TFGF. In addition, the paper presents some new findings pertaining to the historic, thermodynamic, and quantum-mechanical roots of the TFGF. To be included in this paper are brief accounts of new possible extensions and applications of the TFGF. These will include the generalization of this interfacial transport theory to the area of time-varying fields, and the possible realization of absolute theoretical predictability of electronic, and optoelectronic, solid state device characteristics. (Edited author abstract) 42 refs.

**096506 NEW THEORETICAL MODEL FOR A p-n JUNCTION REALISTIC DIODE.** Attempts have been made to give a new theoretical model for semiconductor bipolar realistic diodes. The fact that the realistic devices are not completely free from the effects of traps, defects, band to band radiative and non-radiative (Auger effect) transitions etc., leads to the mathematical solutions which show oscillatory variations (between two positive values) in the carrier density distributions. This leads to the deviation of a diode characteristics from those of the ideal diode. An application of the model has been made to a p-n junction. Experimental evidence of this deviation in Schottky heterostructures found in the literature can act as a direct support of the model. (Edited author abstract) 14 refs.

Khan, W.I. (Univ of Leeds, Leeds, Engl). *Solid State Electron* v 30 n 12 Dec 1987 p 1221-1225.

**096507 FABRICATION OF P-N JUNCTION DIODES USING HOMOEPITAXIALLY GROWN 6H-SiC AT LOW TEMPERATURE BY CHEMICAL VAPOR DEPOSITION.** Homoepitaxial growth on a 6H-SiC (0001)Si face was carried out successfully at 1500°C by chemical vapor deposition. This temperature is 300°C lower than typical well-known growth temperatures. The p-n junction diodes were fabricated with the grown layers and showed very good rectification. The breakdown electric field was estimated to be  $2.4 \times 10^6$

V/cm using the characteristics of the p-n junction diodes. This value is comparable with high-temperature grown layers. The fabricated p-n junction diodes showed blue light emission in the forward-biased region. (Author abstract) 16 refs.

**096508 DOUBLE HETEROSTRUCTURE GaAs TUNNEL JUNCTION FOR A AlGaAs/GaAs TANDEM SOLAR CELL.** A double hetero (DH) GaAs tunnel diode which consists of a GaAs tunnel junction sandwiched between  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  layers has been grown by molecular beam epitaxy, and its annealing characteristics studied. DH tunnel diodes have the advantage that a decrease in the tunnel peak current density due to annealing is greatly suppressed compared to conventional GaAs diodes without AlGaAs layers. In-depth profiles of dopants indicate that the AlGaAs layers act as blocking layers against Be diffusion, which causes a degradation of the diodes. An  $\text{Al}_{0.4}\text{Ga}_{0.6}\text{As}/\text{GaAs}$  tandem solar cell incorporating the DH tunnel junction as interconnectors has achieved a conversion efficiency of 20%. (Author abstract) 10 refs.

**096509 HIGH-SPEED NON-LINEAR CIRCUIT MODELS FOR p-n JUNCTION DIODES.** Circuit models for both long-base and short-base p-n junction diodes which are valid for non-linear high-speed and high-frequency operations are presented. The diode model consists of a parallel connection of higher-order dynamic elements and includes the conventional diffusion model as a special case. The new dynamic model can be used for simulating arbitrary p-n junction diode circuits under all operating conditions. In particular, it is capable of simulating realistically the diode's reverse transient behaviour and providing an increasingly accurate approximation to the diffusion equation as the order of the model gets higher. The model is also shown to be capable of reproducing the frequency-dependent small-signal characteristics of p-n junction diodes. (Edited author abstract) 18 refs.

## Laser Applications

**096510 AlGaAs VISIBLE LASER DIODE EMT-TING AT 780 nm.** Room temperature cw operation V-grooved laser diode emitting at 780 nm has been successfully fabricated by two-step liquid phase epitaxy method. Extremely good internal current confinement is achieved by using an n-type current blocking layer grown on the p-type substrate. The threshold currents are uniformly distributed between 35 and 50 mA. Owing to the simple fabrication process, lasing yield as high as 75% can be easily obtained. (Author abstract) 7 refs.

## Low Temperature Effects

**096511 LOW-TEMPERATURE CHARACTERISTICS OF CdS/CuInSe<sub>2</sub> DIODES.** The current-voltage characteristics, relative spectral response and the electron-beam-induced current (EBIC) for CdS/CuInSe<sub>2</sub> devices were measured in the 40-300 K temperature range. The results indicate that, at temperatures below 220 K, two space-charge regions are present and a reversal in the photocurrent, which shows spectral dependence, takes place under forward bias. The characterization of the device junction(s) by EBIC measurements is consistent with the spectral response. (Author abstract) 13 refs.

USA); Ramanathan, V.; Matson, R.J. *Sol Cells* v 24 n 1-2 May-Jun 1988, Proc 8th Photovoltaic Adv Res Dev Proj Rev Meet, Denver, CO, USA, Nov 15-18 1987 p 11-17.

## Materials

**096512 SILICON NITRIDE PASSIVANT FOR HgCdTe n+p DIODES.** A  $\text{SiN}_x$  film deposited by electron cyclotron resonance plasma CVD has been successfully applied as a surface passivant for  $\text{Hg}_{0.7}\text{Cd}_{0.3}\text{Te}$  n+p diodes. The ECR-plasma CVD assures low temperature deposition of  $\text{SiN}_x$  film on HgCdTe. The  $\text{SiN}_x$  has an excellent interface with HgCdTe with a surface-state density as low as  $1 \times 10^{11} \text{ cm}^{-2} \text{ eV}^{-1}$  and a low fixed charge of  $-1.4 \times 10^{11} \text{ cm}^{-2}$ . Measurement of flatband shifts after exposure to humidity verify that the  $\text{SiN}_x$  is more moisture resistant than the conventional ZnS passivant. A diode ( $\lambda_{co} = 5.4 \mu\text{m}$ ) passivated with  $\text{SiN}_x$  had a zero bias resistance of  $4 \times 10^{10} \Omega$  (diode area =  $4.8 \times 10^{-5} \text{ cm}^2$ ) at 77 K. (Author abstract) 9 refs.

**Mathematical Models** See Also LASERS, SEMICONDUCTOR—Theory.

**096513 FREQUENCY DEPENDENCE OF THE INPUT IMPEDANCE OF A DIODE IN A FREQUENCY MULTIPLIER.** A system of equations is obtained showing that the input impedance of a diode in a frequency multiplier (FM) depends on the impedance of the multiplier output matching circuit (MC). Frequency functions of the input impedance of a diode in a FM are calculated for a single- and double-circuit MC. It is noted that optimum matching with a real input impedance in a FM can be achieved with smaller losses than that achieved with the RC equivalent to the input impedance of a multiplier diode with a given frequency band. (Author abstract) 6 refs.

Savchenko, S.M. *Sov J Commun Technol Electron* v 32 n 2 Feb 1987 p 95-100.

**096514 SIMULATION OF GaAs p-i-n DIODES.** GaAs p-i-n diodes have been modeled using numerical simulation, and the theoretical results have been compared to those of experiment. The simulations predict that with a lifetime of the carriers of  $10^{-7}$  s, devices that have good i-layer modulation may be built. This is in agreement with currently available commercial devices. 12 refs.

Gopinath, A.; Atwater, H. *IEEE Trans Electron Devices* v 35 n 4 Apr 1988 p 414-417.

**096515 NEW DEVICE - A POWER SEMICONDUCTOR DIODE WITH AN INTEGRATED THERMAL SENSOR.** A power semiconductor diode with an integrated thermal sensor is introduced. Means for producing such a device are presented, and the resulting device is analyzed. The theoretical model agrees with the experimental results within 10%. The practical conditions in which the sensor can be used are discussed. 2 refs.

**Measurements** See Also ELECTRIC MEASUREMENTS—Capacitance; SEMICONDUCTOR DEVICES, SCHOTTKY BARRIER; SEMICONDUCTOR DIODES, TUNNEL—Oscillations.

**096516 CHARGE COLLECTION IN SURFACE BARRIER DIODES.** 340 keV protons and 5.5 MeV alpha particles have been employed to measure the window thickness of silicon surface barrier diodes that have undergone oxidation in potassium dichromate solution, steam oxidation and oxygen gas aging. It has been found that the window thickness is independent of the silicon resistivity (300-11,000  $\Omega\text{cm}$ ) and that the dead layer part of the window cannot be treated as a simple geometric

layer. A model has been developed to explain this by considering charge collection and loss mechanisms. The model considers the creation of a plasma along the track of the particle; the expansion and erosion time of the plasma constitute the total time during which recombination of carriers may take place at the surface. The window thickness is given by  $W_x = -A \ln E_0 + B$ , where  $E_0$  is the maximum field in the depletion layer and A, B are constants. The constants A and B have been extracted from the experimental results and compared with the calculated ones. (Author abstract) 10 refs.

Haque, A.K.M.M. (South Bank Polytechnic, London, Engl); Hasko, D.G. *J Phys D* v 20 n 10 Oct 14 1987 p 1284-1290.

**096517 MEASUREMENT OF PULSE VOLTAGE IN HIGH-CURRENT DIODE BY MEANS OF GERMANIUM SENSORS.** A method for measurement of voltage directly in the gap of a high-current diode is described. The method is based on measurement of bremsstrahlung attenuation in absorbing filters. An algorithm is described for calculation of the bremsstrahlung attenuation on which the method is based. The time resolution was 7 nsec and was determined by the frequency response of the recording apparatus. (Author abstract) 2 refs.

**096518 VERTICAL STORAGE TRENCH GATED DIODE LEAKAGE.** A vertical gated diode structure is inherent in the DRAM trench capacitor. A leakage mechanism of considerable magnitude, associated with this structure, is described. The leakage is due to minority carrier generation which occurs at the heavily doped silicon-substrate trench-oxide interface. The carriers are transported in the trench sidewall channel along the dielectric interface to the nearest reverse-biased junction. In a cell design without a well, minority carriers travel vertically in the trench sidewall channel to the storage node diffusion, reducing the DRAM cell retention time. In a cell within a well, the carriers are collected at the well-substrate junction instead of the storage node. 3 refs.

**096519 MEASURING BEAM LEADED DIODES NONDESTRUCTIVELY.** A nondestructive technique for measuring the capacitance and forward-biased resistance of beam-leaded diodes (BLDs) is introduced. The method involves the use of vacuum hold-down rather than permanent attachment of the diode, permitting its removal. The results of measurements on a p-i-n diode are given, but similar utility exists for Schottky detector and mixer BLDs. The calculations demonstrate the sensitivity of the circuit contributions to the effective installed capacitance of a BLD in a microwave transmission line. This suggests the desirability of utilizing not only a microwave circuit characterization of candidate beam-leaded diodes but also one which uses as similar a transmission-line topology as possible to that of the intended end use. 5 refs.

**096521 SEMICONDUCTOR DIODES IN MICROWAVE CONTROL DEVICES. A SURVEY.** The state of the art and the problems that arise in utilization of microwave switching and limited diodes are discussed. Impedance characteristics of microwave p-n diodes are analyzed. Problems associated with increasing the working power, speed, and maximum frequency are considered together with the prospects for the paths toward further improvement in control devices for the centimeter and millimeter wavebands. (Author abstract) 55 Refs.

Lebedev, I.V.; Shnitnikov, A.S. *Radioelectron Commun Syst* v 30 n 10 1987 p 3-10.

**096522 BEHAVIOR OF A MICROWAVE LIMITER DIODE WITHIN THE WORKING FREQUENCY BAND AND OUTSIDE THE BAND.** Limiter diodes with p-n structures that have a thin lightly doped base region are widely employed to protect high-sensitivity input stages of microwave radio receivers. These devices are subject to inconsistent requirements for operation in sharply differing low- and high-power regimes with rapid transition from one to another. The physical processes that take place in a semiconductor structure under the action of a microwave signal with high power level are complicated and have not been adequately studied. We report results of an analysis of the operation of a limiter diode at different frequencies. The influence of the avalanche-multiplication effect on the parameters of the device is considered. 4 Refs.

Shnitnikov, A.S.; Filatov, N.I. *Radioelectron Commun Syst* v 30 n 10 1987 p 99-101.

**096523 MICROWAVE FREQUENCY OPERATION OF THE HETEROSTRUCTURE HOT-ELECTRON DIODE.** The generation of microwave frequencies by the heterostructure hot-electron diode (H<sup>2</sup>ED) is discussed. At 77 K, self-oscillation has been produced over a broad frequency range from direct current to 10.5 GHz, limited by the parasitic series resistance and capacitance. Considerations of the bias polarity required to produce oscillations and of their high-frequency response support a model of switching from tunneling to thermionic emission. 10 refs.

**Modeling** See TRANSISTORS, BIPOLAR—Modeling.

**Noise** See Also NOISE, SPURIOUS SIGNAL—Mathematical Models.

**096525 MEASUREMENT OF THE FLICKER NOISE PARAMETERS OF MIXER AND VARACTOR DIODES.** Flicker noise, the spectral density of which varies approximately inversely as the frequency, is observed in all semiconductor devices. No single theoretical model exists for flicker noise. Because of modulation effects this noise has a significance influence on the spectral characteristics of self-excited oscillators, power amplifiers, frequency multipliers, mixers and autodyne receivers. No single theoretical model exists for flicker noise. This paper presents the results of measurements of the flicker noise characteristics of widely used gallium-arsenide Schottky-barrier mixer diodes 3A110A and 3A111A and the 2A605A, 2A605E and 2A609A silicon multiplier diodes. 14 refs.

## Noise, Spurious Signal

**096526 NOISE FIGURE PERFORMANCE OF A MICROWAVE MIXER DIODE WITH THE COMPLETE DIODE MODEL.** An analysis of thermal and Schottky noise generated in a microwave mixer diode has been made, based on the complete model which describes the diode in a more accurate manner than hitherto. In order to show the effects of the linear and nonlinear diode parasitic reactances on noise figure of a mixer diode which is in either series or shunt configuration with the image termination either open- or short-circuited, the performances of the three diode models (which are the complete, purely resistive and small-signal resistive) were compared. For a low-noise mixing process, the questions of which configuration and which image termination were answered. (Edited author abstract) 3 refs.

Gunes, Zeynep Filiz (Yildiz Univ, Istanbul, Turk). *Bull Tech Univ Istanbul* v 38 n 3 1985 p 353-375.

**096527 FLICKER NOISE IN HYDROGENATED AMORPHOUS-SILICON SCHOTTKY DIODES.** Noise measurements have been performed on a-Si:H Schottky diodes with Au and Pt metal contacts. The noise was found to exhibit 1/f behavior with  $0.7 < n < 1.3$ . The theory of flicker noise in intrinsic a-Si:H is further developed for Schottky diodes. The dependence of the noise on temperature and mean d.c. current is explained on the basis of this theory. It is shown that the measurements provide a means of calculating the density and distribution of the gap states. The results are found to be in good agreement with other techniques. They also suggest the presence of a peak in the gap-state density, around 0.4 eV below  $E_c$ . (Author abstract) 9 refs.

**Performance** See Also LASERS, SEMICONDUCTOR—Performance; MICROWAVE LIMITERS—Computer Simulation.

**096528 DEPENDENCE OF MIXING PERFORMANCE OF A SCHOTTKY DIODE ON ITS PARASITICS.** Conversion loss and noise figure variations of a Schottky diode which is in the series configuration with the short-circuited image termination, have been analyzed against its parasitics, which are nonlinear junction capacitance, the spreading resistance, the reverse limit resistance, the lead inductance and the packaging capacitance and the computed results are presented. It has been pointed out that the parasitic reactances are most effective on the performance of the series diode in the most negative bias region; effect of the spreading resistance depends upon the

biasing level, and the diode performance does not depend upon the reverse limit resistance unless it is smaller than 100 K. (Edited author abstract) 9 refs.

Gunes, Zeynep Filiz (Yildiz Univ, Besiktas, Turk). *Bull Tech Univ Istanbul* v 38 n 4 1985 p 435-446.

**096529 BARRIER HEIGHT ENHANCEMENT OF InP-BASED  $n\text{-Ga}_{0.47}\text{In}_{0.53}\text{As}$  SCHOTTKY-BARRIER DIODES GROWN BY MOLECULAR BEAM EPITAXY.** Barrier height enhancement of an InP-based  $p^+-n\text{-Ga}_{0.47}\text{In}_{0.53}\text{As}$  Schottky diode grown by MBE has been demonstrated for infra-red photodetector applications. A barrier height of 0.35 eV for  $n\text{-Ga}_{0.47}\text{In}_{0.53}\text{As}$  Schottky barrier diodes, was increased to the effective barrier height of 0.55 eV, with a  $p^+-\text{Ga}_{0.47}\text{In}_{0.53}\text{As}$  surface layer of 30 nm thick. The results show a reverse leakage current density of  $1.5 \times 10^{-3}$  A/cm<sup>2</sup> and a junction capacitance of 0.3 pF, which are comparable to those of  $p\text{-Ga}_{0.47}\text{In}_{0.53}\text{As}$  Schottky-barrier diodes at a reverse bias voltage of 5 V. (Author abstract) 6 refs.

Kim, J.H. (JPL, Pasadena, CA, USA); Li, S.S.; Figueroa, L. *Electron Lett* v 24 11 May 26 1988 p 687-689.

**096530 PERFORMANCE OF SCHOTTKY DIODES AS FAR-INFRARED MODULATORS.** We analyze the performance as a terahertz-frequency modulator of a small-area Schottky diode mounted in a corner-cube antenna. The analysis includes the effects of carrier inertia and dielectric relaxation as modeled by K.S. Champlin and G. Eisenstein. It also includes the effect of the vanishing of the depletion region above the flat-band potential, as modeled by T.W. Crowe and R.J. Matlack. Baseline calculation refers to a 1.4  $\mu\text{m}$  diameter diode operated at a carrier frequency of 2.52 THz and a modulation frequency of 8 GHz, as was used in the experiments of D.M. Watson, E.N. Grossman, and T.G. Phillips. The effects on reflectivity modulation, and therefore on sideband-generation efficiency, of varying the diode parameters are investigated. (Edited author abstract) 16 refs.

Grossman, Erich N. (California Inst of Technology, Pasadena, CA, USA). *Int J Infrared Millim Waves* v 8 n 10 Oct 1987, Pap Presented at the Submillimeter (Terahertz) Receiver Technol Conf, Lake Arrowhead, CA, USA, Apr 7-8 1987 p 1293-1312.

**Processing** See Also SEMICONDUCTOR DEVICES, SCHOTTKY BARRIER—Processing.

**096531 EFFECTS OF PROCESSING CONDITIONS ON THE CHARACTERISTICS OF PLATINUM SILICIDE SCHOTTKY BARRIER DIODES.** A study has been carried out to determine the effects of various processing conditions on the formation of PtSi Schottky barrier diodes. Various surface preparation techniques were experimented. Comparisons were made between oxide etching by wet etch (BHF) and reactive ion etching (RIE) predeposition cleaning by wet etch or in situ Ar sputter cleaning, and the use of different thicknesses of Pt. The interaction between PtSi and the contact metallurgy during subsequent annealing was examined. The study shows that each component has a distinct effect on the quality of the PtSi film. The results indicate that oxide etching by wet etch is probably incomplete, leaving residues or suboxides on the surface of Si substrates which interfere with subsequent PtSi formation. Though RIE seems more effective in removing the oxide, data support the view that a damaged layer of Si is formed, which should be consumed by the PtSi formation for optimum electrical characteristics. Even if the formation of the PtSi is ideal, interaction between the PtSi and a commonly used Ti/Al-Cu/Si contact metallurgy at elevated temperatures could degrade the PtSi film qualities if a suitable diffusion barrier is not used. (Edited author abstract) 20 refs.

## Radiation Effects

**096532 INVESTIGATION OF  $\text{H}^-$  PRODUCTION IN A PULSED POWER DIODE AT 10 GW.** Several experimental runs on the investigation of  $\text{H}^-$  production in various types of pulsed power diodes (reflex and magnetically insulated) at a power level of 10 GW and electron cathode surface current density in the (0.5–) kA/cm range with different prepulse conditions in the anode-cathode (A-C) gap were carried out. The scheme with intermediate ion charge exchange ( $\text{H}^- \rightarrow \text{H}^+$ ) and two stage acceleration was used to identify the  $\text{H}^-$  (or  $\text{D}^-$ ) ions and estimate their relative concentration in the plasma formed at the cathode surface. The measured activation yield of  $^{13}\text{N}$  in the  $^{12}\text{C}(p, \gamma)^{13}\text{N}$  reaction gave values of  $\text{H}^-$  current densities equal to  $(0.25 \pm 0.15) \text{ A/cm}^2$ , which corresponded to (0.5–2)% of  $\text{H}^-$  percentage in the cathode plasma in our experimental conditions. (Author abstract) 7 refs.

**096533 EFFECTS OF THE SPACE ENVIRONMENT ON LASER DIODES.** Laser diodes have been irradiated to investigate their behavior in the space environment. The InGaAsP/InP laser diodes used are manufactured by a technology projected to have high-output-power potential. The principal parameters of the devices, which included InP p-n junctions and double-heterostructure lasers with broad and narrow stripe-geometries, measured during 1 MeV electron irradiation, did not degrade appreciably. The partial annealing of irradiation-induced defects that takes place reduces the ultimate degradation induced by radiation. (Author abstract) 24 refs.

Roux, M. (ONERA-CERT, Toulouse, Fr). *ESA J* v 11 n 2 1987 p 167-183.

**096534 USING RADIATION TECHNOLOGY TO PRODUCE FAST-RECOVERY POWER DIODES.** The influence of electron-irradiation regimes and subsequent thermal annealing on the basis parameters of fast-recovery silicon diodes has been investigated. Concern here is to investigate radiation defects (RD) and to develop a regime for a radiation technology process (RTP) in order to improve a combination of parameters of fast-recovery diodes made of Soviet-produced silicon in accordance with the base technology. 9 refs.

**096535 EFFECT OF ELECTRON IRRADIATION ON INTERFACE STATES OF InP MIS SCHOTTKY DIODES.** The effect of 2 MeV electron irradiation on interface states of a Au/Langmuir-Blodgett film/InP MIS diode has been studied. It was found by deep-level transient spectroscopy measurement that a broad peak induced by the interface states decreased significantly after electron irradiation. Moreover the surface photovoltaic measurement showed two orders of magnitude reduction of the surface recombination velocity. All this evidence shows that electron irradiation could reduce the density of interface states between InP and the Langmuir-Blodgett film. (Author abstract) 8 refs.

**096536 TRANSIENT MEASUREMENTS OF ULTRAFAST CHARGE COLLECTION IN SEMICONDUCTOR DIODES.** Funneling-current transients produced in semiconductor devices are predicted to occur on a picosecond time scale. These transients were measured by using a high bandwidth sampling system. Measurements were made on 1-, 3-, and 10- $\Omega$ -cm silicon low-capacitance diodes and  $10^{16} \text{ cm}^{-3}$  Te-doped GaAs diodes. The data are compared to the Hsieh, Murley and O'Brien, the McLean and Oldham, and the Messenger

models. Risettime versus doping density, peak current, total charge, and amplitude versus bias were measured. Current transients and prompt charge versus energy are presented. 15 refs.

**096537 ETUDE DES INTERFACES Al-GaAs ET InP PREPAREES PAR BOMBARDEMENT IONIQUE DE TRES BASSE ENERGIE (0-200 eV).** [Study of the Al-GaAs and -InP Interfaces Prepared by Low-Energy-Ion Bombardment (0-200 eV)]. A systematic study of the electrical behavior of Schottky diodes using Al-ion cleaned GaAs (InP) was done in the ion energy range 0-200 eV. The main results are: (i) The Schottky barrier height  $\Phi_B$  deduced from I-V characteristics decreases on n-type material and increases on p-type as the ion energy increases. (ii) Thermal annealing becomes less and less efficient as the ion energy increases. (iii) The study of interface states by Schottky capacitance spectroscopy shows the creation of new states, specific to ion etched interfaces. These states are responsible for  $\Phi_B$  modification. (Edited author abstract) 12 refs. In French.

## Reliability

**096538 DEATH BY A THOUSAND CUTS: THE PHYSICS OF DEVICE FAILURE THROUGH A SERIES OF ACTIVATED, MICROSCOPIC EVENTS.** A physical model describes device failure in terms of a series of n microscopic events (such as defect creation) which are describable in terms of an identifiable activation energy. The results show a 'Weibull like' time dependence, but the temperature dependence is not of the simple Arrhenius form. Application is made to the 'dark' leakage current in a PIN photodiode and to the deviation in threshold voltage in a MOSFET. In particular the threshold voltage is shown to depend on a series of activated processes, and the required number of such processes to cause failure increases with the width of the gate electrode. (Author abstract) 8 refs.

**096539 METAL-POLYMER SCHOTTKY BARRIERS ON CAST FILMS OF SOLUBLE POLY(3-ALKYLTHIOPHENES).** We present the results of a study of strong rectification by metal-polymer (Schottky) diodes made by evaporating metal contacts onto films of a soluble semiconducting polymer cast from solution. Poly(3-hexylthiophene), a soluble alkyl derivative of poly(thiophene), and indium contacts form the Schottky diodes. Current-voltage characteristics exhibit rectification ratios in the range 100:1 to 1000:1; the forward current increases exponentially over several decades, whereas a relatively small leakage current flows under reversed bias. Capacitance-voltage data indicate nearly uniform dopant concentration over a depth of about 1500 angstrom. (Author abstract) 14 refs.

## Temperature Measurement

**096541 CRYOGENIC THERMOMETRY AND LEVEL DETECTION WITH COMMON DIODES.** Common silicon diodes, manufactured for room temperature electronics, have been used successfully both for thermometry down to 4 K and for liquid helium level monitoring. Ageing has been checked and a novel level detector is fully described. It is the purpose of the present work to report properties of the glass-encapsulated switching diode 1N914 and the plastic-encapsulated rectifier diode 1N4002 when used as cryogenic thermometers. The common gallium arsenide LED has also been investigated. 8 refs.

**Theory** See MATHEMATICAL TECHNIQUES—Algorithms.

**Tunneling** See Also SEMICONDUCTING GALLIUM COMPOUNDS—Performance.

**096542 BULK TUNNELING CONTRIBUTION TO THE REVERSE BREAKDOWN CHARACTERISTICS OF  $\text{InSb}$  GATE CONTROLLED DIODES.** This work presents measurements and analysis of optimized reverse breakdown characteristics of  $\text{InSb}$   $p^+n$  gate controlled mesa diodes. Surface current contributions were minimized by adjusting the potential of the peripheral gate electrode. The resulting measured breakdown currents are found to be proportional to the junction area and exhibit diode bias and temperature dependence that fit quantitatively to direct band-to-band tunneling theory of one sided abrupt junction devices. The agreement between theory and experiment, achieved without any fitting parameter, confirms that bulk band-to-band direct tunneling mechanism is the fundamental limit for the diodes reverse bias performance. (Author abstract) 11 refs.

**096545 QUANTUM TUNNELING PROPERTIES FROM A WIGNER FUNCTION STUDY.** We use a Wigner function description of a Gaussian wave packet to study tunneling through single and double quantum barriers. We note a tunneling time proportional to  $1/k$  and a constant delay time associated with tunneling for the single barrier. The resonant structure gives rise to peaks in tunneling time associated with the resonant energy of the system. We study the initial distribution for the resonant tunneling diode. This is computed from a scattering state basis. Time evolution of the resonant tunneling system is then performed, yielding transient and steady-state results for the I-V curves. (Author abstract) 15 refs.

## Heterojunctions

**096546 MILLIMETER-WAVE HETEROJUNCTION MITATT DIODES.** An approximate large-signal design theory, fabrication techniques, and experimental results for millimeter-wave transit-time devices are described. The approximate large-signal analysis is used to investigate the power and efficiency of heterojunction and transit-time devices. The analysis results show that significant improvement can be achieved for MITATT (mixed tunnel-avalanche transit-time) and TUNNETT (tunnel transit-time) devices by using heterostructures for velocity modulation. A device fabrication process that uses a novel wafer-thinning technique is presented in detail. This technique allowed the fabrication of millimeter-wave diodes with GaAs thickness of 1.5  $\mu$ m with excellent yield. Both double-drift GaAs IMPATT (impact ionization avalanche transit-time) and heterojunction MITATT diodes were fabricated. The diodes were operated as oscillators between 65 and 93 GHz. A typical power output of 45 mW at 72 GHz for a 1%-duty-cycle, 1- $\mu$ s-pulsewidth operation was obtained. 14 refs.

## Microstructure

**096547 DEFECT MICROSTRUCTURE AND MICROPLASMAS IN SILICON AVALANCHE PHOTODIODES.** Soft, noisy silicon avalanche photodiodes were studied using the SEM electron beam induced current technique and transmission electron microscopy. They were found to contain varying concentrations of (i) diffusion-induced misfit dislocations, (ii) precipitates and (iii) cusps (lines of shallower penetration) in ragged  $p-n^+$  junctions due to dislocation-retarded diffusion. The noise was of classical microplasma form but the sites of this breakdown did not correlate with the precipitates as in most previous cases, but occurred at favored points along the cusps in the  $p-n^+$  junction. Low and intermediate densities of misfit dislocations were found to produce microplasmas with lower breakdown voltages than very high densities. The shallowest misfit dislocations produced the greatest diffusion retardation, suggesting that removal of atoms from the diffusing flux by segregation to the dislocation is the mechanism responsible. (Author abstract) 37 refs.

**Noise** See SEMICONDUCTOR DIODES, PHOTODIODE—Noise.

## Radiation Effects

**096548 MEASUREMENTS OF NATURAL RADIATION EFFECTS IN LOW NOISE AVALANCHE PHOTODIODE.** Low-noise avalanche photodiodes (APDs) were irradiated to determine their sensitivity to the natural space environment. Radiation effects on important APD parameters were determined by exposure to 1.5-MeV electrons from a Van de Graaf generator and to gamma rays from a  $^{60}\text{Co}$  source, both to a total dose of 300 krad (Si). During irradiation, the dc dark current and an associated  $1/f$  noise were found to increase linearly with dose only if bias voltage was applied. A  $t^{-x}$  annealing behavior was observed. Radiation-damage coefficients, threshold dose rates, and threshold fluences are calculated. 8 refs.

## Design

**096549 USE OF THE QUASI-HYDRODYNAMIC METHOD TO CALCULATE THE IMPEDANCE OF GUNN DIODES WITH BALLISTIC ELECTRON MOTION.** Generalized relations are obtained for the propagation constants of spacecharge waves in semiconductors with negative differential mobility using the quasi-hydrodynamic method. An analytical expression is obtained for the microwave impedance of GaAs Gunn diodes having a structure of the type  $n^+-n-n^+$ . It is shown that unlike existing relations, this relation enables the ballistic or noncollisional nature of the motion of the charge carriers in a Gunn diode to be taken into account in the millimeter wave band. (Author abstract) 10 refs.

## Electric Properties

**096550 EXPERIMENTAL DETERMINATION OF THE DEPENDENCE OF THE ADMITTANCE OF A GUNN DIODE ON THE AMPLITUDE OF THE A-C VOLTAGE AND THE FREQUENCY.** The dependence of the admittance of the active region of an AA-703 diode on the amplitudes of the ac voltage across it are investigated for several frequencies (9.0, 9.1, 9.2, 9.3, 9.4, 9.5 and 9.8 GHz) by the self-excited oscillator method with a varying load. The parameters of the equivalent circuit of the diode case, the load impedance in the plane of the diode and the power absorbed by this load are measured. The results obtained are used to calculate the admittance of the diode and the voltage amplitude. The measurement method is described and the results obtained are presented and discussed. (Author abstract). 10 Refs.

## Testing

**096552 NONRECIPROCALITY IN A GUNN DIODE IN CROSSED STATIONARY ELECTRIC AND MAGNETIC FIELDS.** The effect of a magnetic field on the characteristics of Gunn diodes has been investigated by a number of research workers. It was found, in particular, that there is a change in the threshold electric field when the diode is placed in a stationary magnetic field. The observed changes in the characteristics are due to the magnetoresistive effect. Only the dependence of the characteristics of the Gunn diode on the value of the magnetic field were investigated, and the dependence of the characteristics on the direction of the magnetic field was ignored. 7 refs.

Usanov, D.A.; Skripal, A.V. *Radioelectron Commun Syst* v 30 n 5 1987 p 53-55.

**096553 FEATURES OF THE OSCILLATORY CHARACTERISTICS OF MILLIMETER-BAND GUNN DIODES.** An investigation of the form of the oscillatory characteristics of Gunn diodes enables one to explain the features of the oscillation build up process, and enables one to make recommendations for choosing the optimum value of the load admittance and the supply voltage of a Gunn-diode generator. The results of the investigation enable us to explain why it is possible in practice to obtain self-excited oscillations when a Gunn diode operates in a series-oscillatory circuit. 1 ref.

## Analysis

**096557 SIMPLIFIED FIELD ANALYSIS OF A DISTRIBUTED IMPATT DIODE USING MULTIPLE UNIFORM LAYER APPROXIMATION.** A small-signal field analysis of a distributed IMPATT (impact avalanche and transit time) diode is presented. The active region of the diode is assumed to consist of a uniform avalanche layer and avalanche-free drift layers. The propagation constant and field distributions are obtained without numerical solution of differential equations. The effects of losses caused by the presence of inactive layers are included in the analysis. Numerical examples of GaAs double-Read distributed IMPATT diodes are given which show the dependence of the amplification characteristics on the thicknesses of the avalanche and drift layers. 11 refs.

## Calculations

**096558 COMPUTATION OF LARGE SIGNAL GaAs IMPATT DIODE PARAMETERS FROM CLOSED FORM ANALYTICAL SOLUTION.** The paper discusses the computation of the large signal admittance and power in Read and abrupt junction structures based on the approximate closed form solution and considering the basic device structure parameters. The results have been compared with the simulation results on the more realistic Read model and found satisfactory throughout a fairly large RF voltage range. The applicability of the analysis for optimum device design is as good as the simulation, with the advantages of lower cost and greater simplicity in terms of the computer program involved. (Author abstract) 11 refs.

## Measurements

**096560 MEASUREMENT OF LOSS RESISTANCE AND AVALANCHE FREQUENCY OF IMPATT DIODES.** Direct methods for measuring loss resistance and the avalanche frequency  $\Omega$  of IMPATT diodes involve difficulties associated with analysis of measurement-chamber parameters and processing of the experimental results. As the frequency goes up these difficulties increase. It is precisely at the shortwave end of the microwave range that the advantages of IMPATT diodes over other types of semiconductor devices are particularly apparent, however. A technique for measuring avalanche frequency and loss resistance of IMPATT diodes is outlined. Its principal advantages are as follows: the possibility of employing simple measurement sections requiring no calibration; the improved frequency range of measurements; the possibility of measuring the parameters of caseless diodes; universality; and the greater ease of determining and processing the experimental results. 4 Refs.

Skachko, V.I.; Kosinskii, V.S.; Gorlachev, V.E. *Radioelectron Commun Syst* v 30 n 10 1987 p 89-91.

## Millimeter Waves

**096561 ANALYSIS OF A MILLIMETER-WAVE IMPATT DIODE BY A MODIFIED READ MODEL.** A modified Read model analysis is proposed for millimeter-wave IMPATT diodes. The energy relaxation time and the ionization rates which have been obtained from the microscopic model are taken into account in this modified analysis. The validity of applying this analysis to millimeter-wave IMPATT diodes is examined. (Author abstract) 4 refs.

**096564 1.3μm WAVELENGTH InGaAsP/InP LIGHT EMITTING DIODES.** A 1.3μm wavelength InGaAsP/InP light emitting diode has been developed as a light source for optical fiber transmission systems. High-radiance and high-speed performance are achieved by the use of double heterostructure and current confinement structure. When this light emitting diode is coupled to a 50μm core 0.2-NA graded-index fiber, the optical power is 15μW at 50mA current. The cut-off frequency at -3db optical output power is 100 MHz at 50 mAdc with 10% modulation. The diode has a high reliability with an estimated half-power lifetime of 10<sup>7</sup> hours at room temperature. (Author abstract) In Japanese. 8 refs.

**096565 COUPLING EFFICIENCY OF SURFACE-EMITTING LED'S TO SINGLE-MODE FIBERS.** Using coherent-mode representation, the light emission of a surface-emitting LED (SELED) with a Lambertian far-field and a uniform near-field intensity is expressed by coherent modes. The coupling efficiency of the SELED to a single-mode fiber is calculated as the weighted sum of the coupling efficiencies of the coherent modes to the fiber mode. The absolute maximum achievable efficiency is found to be the inverse of the number of the coherent modes, and is equal to  $(\lambda^2/\pi A)$ , where  $\lambda$  is the LED emission area and  $A$  is the emission wavelength. This efficiency can be obtained by butt coupling if the LED area  $A$  is about equal to or larger than the fiber mode size. The theoretical prediction agrees well with published experimental data. 19 refs.

**Efficiency**

**096568 RED AlGaAs LIGHT-EMITTING DIODES.** HP has recently released indicator and display products containing a new type of red light-emitting diode (LED) based on the aluminum gallium arsenide (AlGaAs) materials system. These LEDs offer a significant improvement in efficiency over the red LEDs that have previously been available but cost only slightly more. This paper provides an overview of the different types of AlGaAs devices that are available and compares their performance to that of the other red LED technologies. (Edited author abstract).

**Fabrication**

**096570 PREPARATION OF GAP RED LED'S BY LIQUID PHASE EPITAXY.** A liquid phase epitaxy system with rotation boat design has been developed to grow GaP epitaxial layers for red light emitting diode applications. The optimum growth condition was determined by optimizing both the light emission intensity and the uniformity of diodes fabricated from each wafer. Gap red light emitting diodes with an average quantum efficiency of 2.9% were routinely obtained. The maximum quantum efficiency was 3.5% for an uncoated diode driven with a current density of 6.3 A/cm<sup>2</sup>. (Author abstract) 8 refs.

**096571 ERBIUM-DOPED GaAs LIGHT-EMITTING DIODES EMITTING ERBIUM f-SHELL LUMINESCENCE AT 1.54 μm.** GaAs light-emitting diodes emitting at 1.54 μm have been fabricated using Er-doped GaAs grown by metal organic chemical vapour deposition, and the output characteristics are reported. Characteristic emission from the internal 4f-shell transitions of erbium is observed even at room temperature, and the wavelength shifts by less than the measurement resolution of 1 nm over the temperature range from 180 K to 296 K. These results confirm the possibility of fabricating stable light sources using rare earth doped semiconductors. (Author abstract). 10 Refs.

**Junctions**

**096573 CARRIER INJECTION MECHANISM IN AN A-SIC P-I-N JUNCTION THIN-FILM LED.** A systematic study has been done on the carrier injection mechanism and electroluminescent properties of an amorphous silicon-carbide p-i-n junction thin-film light-emitting diode (a-SiC TFLED). The analysis of the junction characteristics reveals that the main contribution to the junction current comes from electrons injected by tunneling from the n-layer through the i-n interface notch barrier, while the electroluminescent property of the TFLED is determined by the injection process of holes. This process also takes place by tunneling, in this case from the p-layer through the p-i interface notch barrier. On the basis of the results of the analysis, a method to improve the LED performance using a hot-carrier-tunneling injector structure is proposed. With this structure, the brightness of the TFLED is increased by more than one order of magnitude to about 20 cd/m<sup>2</sup>, with an injection current density of 600 mA/cm<sup>2</sup>. 10 refs.

**Optical Properties**

**096575 MINORITY-CARRIER GENERATION AND RECOMBINATION IN 1.35 μm InGaAsP/InP DOUBLE HETEROSTRUCTURE DIODES.** In mesostructure diodes with differently spaced p-n and heterojunctions the electron-beam induced current and cathodoluminescence, C-U characteristics, DLTS, and photoreponse as well as the injection luminescence as functions of the wavelength, temperature, and time were measured. The InP-interlayer suppresses the collection of the photogenerated holes by means of the valence band offset-induced pile-up effect at low illumination levels and low temperatures, delays the motion of the holes during the collection at high illumination levels and reduces the hole injection into the n-type quaternary active layer at low temperatures. Due to the separation of the p-n junction from the active layer, the content of nonradiative recombination centres in the active layer is reduced. (Edited author abstract). 20 Refs.

Rheinlander, R. (Karl-Marx-Univ Leipzig, Leipzig, East Ger); Grummt, G.; Kovac, J.; haefer, H.; Heilmann, R. *Phys Status Solidi A* v 107 n 1 May 1988 p 405-418.

**096576 PROPERTIES OF RED LIGHT EMITTING (Al,Ga)As DOUBLE HETEROSTRUCTURE DIODES.** Using the spectral response of the photocurrent, various modes of a scanning electron microscope, photo and injection luminescence as well as the capacitance-voltage technique, the characteristic parameters of GaAlAs diode structure and material properties were investigated and compared with the brightness of the LEDs. The experiments involving different temperatures reveal insights into the injection properties at the heterobarriers. The metallurgical transition position outside the active layer near the heterojunction simultaneously ensures a high injection and material efficiency in the active region. The internal efficiency of the best diodes is about 55 percent at room temperature and is limited by the population of the indirect gap minima of the conduction band with rising AlAs-content. (Author abstract). 9 refs.

## Performance

**096577 BUTT COUPLING EFFICIENCY OF LONG-WAVELENGTH EDGE-EMITTING LEDs TO SINGLE-MODE FIBERS.** Butt coupling efficiency between edge-emitting LEDs operating at 1.3 and 1.55  $\mu\text{m}$  wavelengths and single-mode fibers, has been investigated using far-field pattern data. (Author abstract) 18 refs.

Ghafoori-Shiraz, H. (Anritsu Corp, Atsugi, Jpn). *Trans Inst Electron Inf Commun Eng Sect E (Engl)* v E70 n 7 Jul 1987 p 617-620.

**096578 BACK LIGHTING USING ARGUS LEDs.** Argus LEDs were developed for applications requiring homogeneous light over large areas, since their light emission covers a fairly large solid angle. With this special feature, Argus LEDs further extend the wide range of standard LEDs which are mainly suitable for switching or operating status indication, because their radiation is concentrated in the axial direction. The benefits of Argus LEDs can be fully utilized if an external reflector and a diffuser are used. In this arrangement, an even level of light from areas, symbols and characters is achieved.

Kristufek, Peter (Siemens AG, Munich, West Ger). *Displays* v 9 n 2 Apr 1988 p 85-87.

## Reliability

**096579 RELIABILITY OF LEDs AND QUATERNARY PHOTODIODES.** The reliability of GaAlAs and InGaAsP LEDs, and InGaAsP photodiodes, which have been used in the fiber-optic video distribution system, is studied. All devices are found to be sufficiently reliable. The study also showed that: (a) GaAlAs LEDs with Al content as large as 0.78  $\mu\text{m}$  band-gap have reliability comparable to the usual 0.8  $\mu\text{m}$  band-gap LEDs, (b) homogeneous degradation of InGaAsP LEDs is caused by electrode migration, (c) InGaAsP photodiodes do not endure electrical-surge as well as Ge photodiodes, and (d) discontinuous bias application improves device reliability. (Author abstract) 9 refs. In Japanese.

## Research

**096580 PHOTOCONDUCTIVE INFRARED EXCITATION SPECTRUM OF GaP DIODE WAFERS AND APPLICATION AS AN INFRARED IMAGING SYSTEM.** The photoconductive excitation spectrum of GaP:N (ZnTe) diodes was measured irradiating the samples from p- and n-side under forward and reverse bias conditions. The ionization thresholds of S and Te donors as well as transitions from their ground states to excited

bound levels with subsequent ionization by the electric field can be observed. The observed minima in the continuum above the ionization threshold are due to phonon assisted fast recombination. (Edited author abstract) 9 refs.

**096581 ENERGY TRANSFER INTO AND OUT OF MANGANESE IN THE ELECTROLUMINESCENCE OF ZnS:Mn AND ZnSe:Mn.** The response of electroluminescent Schottky diodes of ZnS:Mn and ZnSe:Mn to short drive pulses has been investigated. There is evidence for energy transfer into the manganese from centres which can be more efficiently excited, in addition to the impact excitation of the manganese centres themselves, and for energy transfer out of manganese into non-radiative centres. In ZnS:Mn the transfer processes into and out of manganese can be treated as being independent, and at low concentrations the decay follows the Forster law. In ZnSe:Mn the transfer into and out of manganese is correlated and there is no simple form for the decay curve. (Author abstract). 17 refs.

## Testing

**096582 LIFETIME TEST FOR HIGH-CURRENT-INJECTION STRAINED-LAYER SUPERLATTICE LIGHT-EMITTING DIODE.** The successful long-term operation of  $\text{GaAs}_{1-y}\text{P}_y\text{-In}_x\text{Ga}_{1-x}\text{As}$  strained-layer superlattice (SLS) light-emitting diodes under high constant current injection is discussed. This SLS can be grown ( $y \approx 2x$ ) with average lattice constant that matches that of the GaAs substrate. The LED structure grown by MOCVD (metalorganic chemical vapor deposition) on n-GaAs substrate consists of 10 periods of undoped  $\text{GaAs}_{1-y}\text{P}_y\text{-In}_x\text{Ga}_{1-x}\text{As}$  SLS sandwiched between p<sup>+</sup>- and n-GaAs films. A 3000-angstrom  $\text{SiO}_2$  layer was deposited by plasma-assisted CVD to make a 6- $\mu\text{m}$ -wide stripe structure. Diodes with typical dimensions of  $25 \times 300 \mu\text{m}^2$  were fabricated and showed ideality factor in the range between 2 and 3. Room-temperature lifetime tests were carried out for several devices ( $x = 0.1, y = 0.2$ ) at current injection of  $4000 \text{ A/cm}^2$ , for diodes emitting at 0.94  $\mu\text{m}$ . No degradation in the optical intensity was observed after more than 2000 h of operation. The EL spectral peak position remained unchanged while the spectral line width increased by about 5.7 meV during the test period. By varying the value of x, LEDs emitting at wavelength in the range from 0.9 to 1.1  $\mu\text{m}$  were achieved. The emission properties and lifetime of these LEDs are discussed.

**096583 TWO-DIMENSIONAL PHOTODIODE USING a-Si PIN DIODES.** This paper proposes a two-dimensional photodiode composed of an a-Si pin junction. The photodiode is constructed on the glass substrate. The pixel of the sensor is of a simple structure

composed of two photodiodes connected in opposite directions between the vertical and the horizontal signal lines. The photodiode constructed by a-Si pin junction has the function of the blocking diode, preventing the crosstalk in reading out the signal, in addition to the photoelectric conversion. A two-dimensional  $5 \times 5$  photosensor was constructed experimentally, and the basic operation was verified. (Edited author abstract) 10 refs.

**096584 MBE GROWN MONOLITHIC INTEGRATED InGaAlAs/InP RIDGE WAVEGUIDE PHOTODIODES.** The first monolithic integration of a low loss InGaAlAs Ridge waveguide with a low leakage InGaAs photodiode is demonstrated. The structure has been grown by molecular beam epitaxy on a n<sup>+</sup>-InP substrate, using an InGaAlAs layer with a bandgap of 1.29  $\mu\text{m}$ , suitable for waveguiding at 1.55  $\mu\text{m}$  wavelength. Absorption of the guided light is provided by leaky coupling from the InGaAlAs guiding layer into the higher index InGaAs absorbing region containing a p/n junction. The devices showed external quantum efficiencies as high as 20% for operation at 1.55  $\mu\text{m}$  wavelength. This is the first demonstration of a monolithic integrated waveguide device in the InGaAlAs/InP material system. (Author abstract) 28 refs.

**096585 LIGHT SENSING WITH OPTICAL ICS.** Traditionally photodiodes have been used in conjunction with hybrid amplifier circuitry to perform certain signal processing applications, e.g. light current amplification, light threshold detection and light demodulation. But because photodiodes can be built out of silicon, this has given the IC designer the ability to fabricate both the hybrid circuitry and the photodiode on the same silicon substrate. The article reviews optical sensor applications, absolute light measurement, optocouplers-optoisolators, and rotary position encoding using optical emitter-detector assemblies.

**096591 TUNABLE SUPERLATTICE P-I-N PHOTODETECTORS: CHARACTERISTICS, THEORY, AND APPLICATIONS.** Extended measurements and theory on the recently developed monolithic wavelength demultiplexer consisting of voltage-tunable superlattice p-i-n photodetectors in a waveguide configuration are discussed. It is shown that the device is able to demultiplex and detect two optical signals with a wavelength separation of 20 nm directly into different electrical channels at a data rate of 1 Gb/s and with a crosstalk attenuation varying between 20 and 28 dB, depending on the polarization. The minimum acceptable crosstalk attenuation at a data rate of 100 Mb/s is determined to be 10 dB. The feasibility of using the device as a polarization angle sensor for linearly polarized light is also demonstrated. A theory for the emission of photogenerated carriers out of the quantum wells is included, since this is potentially a speed limiting mechanism in these detectors. It is shown that a theory of thermally assisted tunneling by polar optical phonon interaction is able to predict emission times consistent with the observed temporal response. 61 refs.

## Analysis

**096592 ANALYSIS OF A PIN PHOTODIODE WITH INTEGRATED WAVEGUIDE.** The absorption coefficient of an InGaAs PIN photodiode integrated with an InGaAsP-InP waveguide is analyzed by means of the mode-matching technique. The results compare excellently to published data for  $\lambda = 1.3 \mu\text{m}$ . It is shown that by an optimized device structure the absorption coefficient can be increased to about 0.15 dB/ $\mu\text{m}$ , enabling reduced detector length and smaller capacitance. (Author abstract) 5 refs.

Amann, M.-C. (Siemens AG, Munich, West Ger). *Electron Lett* v 23 n 17 Aug 13 1987 p 895-897.

**096593 MULTILAYER APDs PRODUCING UP TO TWO IMPACT IONISATIONS PER CARRIER PER STAGE: OPTICAL RECEIVER PERFORMANCE ANALYSIS.** Previous analyses of the gain and noise properties of superlattice avalanche photodiodes (APDs) are extended to allow for the production of up to two impact ionizations per initiating carrier per stage. The sensitivity of optical receivers employing these advance APD structures is determined, allowing for the influence both of residual hole ionization and dark current. These devices are found to have higher gain and noise figures than their single ionization electron counterparts. Receiver sensitivity studies are reported, which indicate that dark current and residual hole ionization are of increased significance, but that provided these effects are small, improved performance is obtained. (Author abstract) 42 refs.

Fyath, R.S. (Univ Coll of North Wales, Bangor, Wales); O'Reilly, J.J. *IEE Proc Part J* v 135 n 2 Apr 1988 p 101-108.

**096594 InP/Ga<sub>0.47</sub>In<sub>0.53</sub>As SUPERLATTICE AVALANCHE PHOTODIODE.** The article reports a theoretical study on the photoresponse characteristics of an InP/Ga<sub>0.47</sub>In<sub>0.53</sub>As superlattice p<sup>+</sup>i-n<sup>+</sup> APD for operation in the 1-1.6  $\mu\text{m}$  wavelength region. It has been found that the  $\beta/\alpha$  ratio for the structure is 16 for an electric field  $E = 3 \times 10^7/\text{m}$ . The device is thus expected to become an attractive low-noise detector for fiber-optic communication systems. The device has a quantum efficiency of 60% at  $\lambda = 1.3 \mu\text{m}$ . The bandwidth of the response curve is approximately 100 MHz. (Author abstract). 6 Refs.

**Applications** See Also INTERFEROMETRY, HOLOGRAPHIC; OPTOELECTRONIC DEVICES—Design.

**096595 MONOLITHIC PIN/AMPLIFIER PHOTORECEIVER.** An InGaAs/InP monolithic photoreceiver, in which a pin photodiode and a preamplifier are integrated, has been developed. The 8610 type photoreceiver (IMSO8610) has been developed so as to be applied to the systems with bit rates up to 400 Mb/sec. It operates with a single 5v power supply. A transimpedance of 965 ohms and a 3db cut-off frequency of 240 MHz have been obtained. The photoreceiver is so reliable that it can be used practically. In addition, a self-aligned FET with a cut-off frequency of 3 GHz has been developed to fabricate a higher-speed photoreceiver. (Author abstract) In Japanese. 9 refs.

Matsuda, Kenichi (Matsushita Electric Industrial Co, Jpn); Kubo, Minoru; Tojo, Masaaki; Ohnaka, Kiyoshi; Shibata, Jun. *Natl Tech Rep Matsushita Electr Ind Co* v 34 n 1 Feb 1988 p 35-40.

**096596 SIMPLE DATA LINK FOR PLASTIC FIBERS.** A simple data link which employs single-chip integrated photodetectors consisting of photodiodes and amplifiers has been developed. The link is of the single direction type and the twin direction type, with the features of open-collector output, small size and low cost. The simple data link makes possible easy development of

optical signal transmission system in new-medium communications, factory automation and office automation, as well as miniaturization of the equipment. The paper describes the design, characteristics and reliability test results of the optical connector modules comprising optical components. Also, it discusses the main characteristics of the simple data links in which these modules are employed. (Author abstract) In Japanese. 2 refs.

**096597 INVESTIGATION OF AN OPTOELECTRONIC NONLINEAR EFFECT IN A GaInAs PHOTODIODE, AND ITS APPLICATION IN A COHERENT OPTICAL COMMUNICATION SYSTEM.** A nonlinear mixing effect has been predicted theoretically, and measured using a GaInAs PIN photodiode. The nonlinear effect has been simulated using a small signal finite difference model. The variation of the effect has been measured over the frequency range 1.2-15 GHz for a number of bias voltages from 5 to 20 v, and the effect has been shown to be optoelectronic in origin. A high frequency heterodyne experiment has been performed with the optical and local oscillator signals in the range 10-20 GHz. The difference beat frequency was observed at 500 MHz and 2 GHz. The measured conversion loss was between 27 and 40 db for a 0 dbm local oscillator signal. The application of the optoelectronic mixing effect to optical fiber frequency domain multiplex systems for the dissemination of frequency standards has been considered. (Author abstract) 18 refs.

**096598 LOW ENERGY X-RAY AND GAMMA SPECTROSCOPY USING SILICON PIN PHOTODIODES.** An energy resolution of 1.43 keV (FWHM) for the 59.55 keV <sup>241</sup>Am  $\gamma$ -ray line at 19°C was obtained by using low-cost silicon PIN photodiodes. The dependence of energy resolution on detector and preamplifier temperature was investigated. At -40°C a FWHM of 1.04 keV was reached. Low energy Mn and Ti K X-ray spectra were also taken, and the 5.9 and 4.5 keV peaks were clearly resolved from the noise. Our measurements show that silicon PIN photodiodes are comparable in performance with the best room temperature silicon detectors which are considerably more expensive. (Author abstract) 5 refs.

Markevich, N. (Technion, Haifa, Israel); Gertner, I.; Felsteiner, J. *Nucl Instrum Methods Phys Res Sect A* v A269 n 1 Jun 1 1988 p 219-221.

**096599 H<sup>+</sup> AND He<sup>+</sup> SPECTROSCOPY USING SILICON PIN PHOTODIODES.** Silicon PIN photodiodes have been used in detecting H<sup>+</sup> and He<sup>+</sup> ions from a 1 Mev accelerator. Energy resolutions (FWHM) from 20 keV (at 16 keV) to 4.7 keV (at 1 Mev) for H<sup>+</sup> and from 3.4 keV (at 22 keV) to 9.8 keV (at 700 keV) for He<sup>+</sup> have been measured at room temperature. Resolution measurements over this energy range using a premium PIPS detector have also been performed. A comparison between the two detectors shows that the photodiodes exhibit better energy resolution over the whole energy range for H<sup>+</sup>, and comparable resolution for He<sup>+</sup>. It is argued that the resolution of the photodiode can be further improved by manufacturing a device with thinner entrance window. (Author abstract) 9 refs.

Markevich, N. (Technion Israel Inst of Technology, Haifa, Israel); Gertner, I.; Felsteiner, J. *Nucl Instrum Methods Phys Res Sect A* v A269 n 3 Jun 20 1988 p 599-602.

**096600 MINIATURE VACUUM PHOTODIODES FOR CALORIMETERS.** Data are presented on the performance of flat vacuum photodiodes 30 mm in diameter and 8 mm in height and with a quantum

efficiency of the photocathode of 24% for NaI(Tl) crystals. The effects of magnetic fields up to 2.3 T have been measured. (Author abstract) 5 refs.

**096601 MONTE CARLO SIMULATION OF BLOOMING AND CROSSTALK IN AN RL1024G DIODE ARRAY.** The RL1024G, a 2-in.-long linear array of 1024 photosensitive diodes, has been modeled by the Monte Carlo method. Good agreement has been obtained with experimental data using a simple model depending on a few parameters. Since the model can predict the signals from the array for a given illumination pattern, it describes the nonlinear response function of the array. Such a description is a prerequisite for the construction of a restoration method that calculates the true illumination from the registered one. 4 refs.

## Electric Properties

**096603 SHORT WAVELENGTH RESPONSIVITY IMPROVEMENT AND LONG WAVELENGTH RESPONSIVITY DEGRADATION IN PHOTODIODES AS A RESULT OF GAMMA IRRADIATION.** Changes in surface and bulk properties of United Detector Technology pin-05D photodiodes as a result of 1.3 Mrad gamma irradiation are compared. Changes in surface properties are seen experimentally to significantly alter overall device characteristics. Changes in device properties include increases in surface conductivity, improved quantum efficiency at visible wavelengths, decreased infrared response, and decreased minority carrier lifetime. The first four results are new and permit differentiation between surface and bulk effects. A model consistent with all of these measurements is presented to explain the changes. The model is based upon gamma ray photodesorption of surface impurities. (Edited author abstract) 11 refs.

## Fabrication

**096604 SMALL-JUNCTION-AREA GaInAs/InP PIN PHOTODIODE WITH MONOLITHIC MICROLENSES.** We report on a back-illuminated GaInAs/InP photodiode with a monolithic microlens that we have fabricated. The photodiode has both an ultrabroad bandwidth of 18 GHz and a high quantum efficiency of about 84%. It achieves this by using a small pin junction area

while maintaining a large fibre alignment tolerance by incorporating an InP microlens. The photodiode capacitance was 20 fF for a junction diameter of approximately 15  $\mu\text{m}$ . (Author abstract) 8 refs.

Makiuchi, M. (Fujitsu Lab Ltd, Atsugi, Jpn); Wada, O.; Kumai, T.; Hamaguchi, H.; Aoki, O.; Oikawa, Y. *Electron Lett* v 24 n 2 Jan 21 1988 p 109-110.

**096605 InGaAs PIN PHOTODIODES ON RECESSED SEMI-INSULATING GaAs SUBSTRATES.** Low leakage current  $\text{Ga}_{1-x}\text{In}_x\text{As}$  pin photodiodes have been fabricated on GaAs substrates by incorporating an  $\text{GaAs/Ga}_{1-x}\text{In}_x\text{As}$  superlattice buffer to accommodate the lattice mismatch. Devices fabricated from  $\text{Ga}_{0.65}\text{In}_{0.35}\text{As}$  on  $n^+$  substrates exhibited leakage currents below 1 nA at  $-10\text{ V}$ , and external uncoated quantum efficiencies of approx. 47% at 1.15  $\mu\text{m}$ . A growth and processing sequence for fabricating devices in recesses on semi-insulating GaAs substrates with a coplanar geometry, to allow subsequent GaAs circuit processing, has been identified, and shown not to introduce a significant leakage penalty. (Author abstract) 8 refs.

**096606 FABRICATION OF MONOLITHIC TWIN-GaInAs PIN PHOTODIODE FOR BALANCED DUAL-DETECTOR OPTICAL COHERENT RECEIVERS.** A monolithic twin-GaInAs/InP pin photodiode with planar, embedded structure has been fabricated for optical coherent receiver applications. High-uniformity ( $\pm 1.5\%$ ) quantum efficiency and low capacitance (0.3 pF) have been achieved, and its advantage has been demonstrated by the intensity noise suppressions of a dual-detector balanced heterodyne receiver (better than  $-15\text{ dB}$  up to 4.2 GHz). (Author abstract) 5 refs.

Wada, O. (Fujitsu Lab Ltd, Atsugi, Jpn); Miura, S.; Mikawa, T.; Aoki, O.; Kiyonaga, T. *Electron Lett* v 24 n 9 Apr 28 1988 p 514-516.

**096607 DESIGN AND PERFORMANCE OF VERY HIGH-SPEED  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}/\text{In}_{0.52}\text{Al}_{0.48}\text{As}$  P-I-N PHOTODIODES GROWN BY MOLECULAR BEAM EPITAXY.** High-speed  $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}/\text{In}_{0.52}\text{Al}_{0.48}\text{As}$  photodiodes were grown by molecular beam epitaxy (MBE) on semi-insulating InP substrates. The measured impulse response characteristics for the photodiodes are very close to the analytically calculated ones. The temporal response to pulsed optical excitation is characterized by a rise time of 21 ps and a width (FWHM) of 27 ps. The  $25 \times 20\text{-}\mu\text{m}^2$  diodes have a junction capacitance  $<0.1\text{ pF}$ , a dark current approx. 1 nA, and a peak responsivity of 0.35 A/W. These characteristics are comparable or better than most epitaxial InGaAs photodiodes reported to date, and made the devices suitable for high-speed applications and monolithic integration. 13 refs.

**096608 PLANAR InP/InGaAsP THREE-DIMENSIONAL GRADED-JUNCTION AVALANCHE PHOTODIODE.** A planar InP/InGaAsP avalanche photodiode, which is fabricated by  $\text{Be}^+$  implantation through a dish-shaped InGaAs mask, has been developed. A three-dimensional graded junction is obtained and a uniform gain as high as 30 is achieved without edge or surface breakdown. The dish-shaped InGaAs implantation mask is formed by a photoelectrochemical etching technique. Device modeling indicates that the graded junction and low doping concentration can prevent edge breakdown and greatly suppress the surface field. The diode has a separated absorption and multiplication structure grown by hydride vapor-phase epitaxy. These devices exhibit low primary dark currents ( $\approx 1\text{ nA}$ ), and high quantum efficiencies close to that of an InGaAs p-i-n at 1.3- $\mu\text{m}$  wavelength. Sensitivity measurements at bit

rates of 1.7 Gb/s give a minimum average receiver power required for  $10^{-9}$  BER of  $-35.5\text{ dBm}$ . 12 refs.

Chi, Gou-Chung (AT&T Bell Lab, Murray Hill, NJ, USA); Muehner, D.J.; Ostermayer, F.W. Jr.; Freund, J.M.; O'Brien, K.J.; Pawelek, R.; McCoy, R.J.; Smith, R.C.; Mattera, Vincent D. Jr. *IEEE Trans Electron Devices* v ED-34 n 11 Nov 1987, 45th Annu Device Res Conf, Santa Barbara, CA, USA, Jun 22-24 1987 p 2265-2269.

**096609 InP/InGaAsP/InGaAs AVALANCHE PHOTODIODES GROWN BY CHEMICAL-BEAM EPITAXY.** With the chemical-beam epitaxy-grown In/InGaAsP/InGaAs avalanche photodiodes (APDs) described, bandwidths as high as 6 GHz in the low-gain regime ( $M < 4$ ) were achieved. This is comparable to the highest bandwidth reported to date for this type of APD. For higher multiplication values, a gain-bandwidth-limited response was observed; the gain-bandwidth product was in the range 25 to 30 GHz. The frequency response of the APDs is explained in terms of five effects: carrier diffusion, the transit time through the depletion region, the RC time constant, charge accumulation at the heterojunction interfaces, and the avalanche buildup time. For example, to minimize hole trapping at the heterojunction interfaces, three thin ( $\leq 700\text{ Å}$ ) InGaAsP ( $E_g = 1.13, 0.95$ , and  $0.80\text{ eV}$ ) transition layers, were incorporated. The other device parameters can be summarized as follows: the total dark current was as low as 3.6 nA at 90% of breakdown and the primary multiple dark current was 1.5 nA. Useful avalanche gains as high as 30 were achieved. The quantum efficiency of uncoated devices at 1.3  $\mu\text{m}$  was approximately 55%. The device capacitance ( $\text{diam} = 40\text{ }\mu\text{m}$ ) was  $<0.1\text{ pF}$  at the operating voltage. 2 refs.

**096610 HIGH-PERFORMANCE GaInAs INTERDIGITATED METAL-SEMICONDUCTOR-METAL (IMSM) 1.3- $\mu\text{m}$  PHOTODETECTOR GROWN ON A GaAs SUBSTRATE.** High-performance photodetectors have been fabricated on GaInAs layers grown on GaAs semi-insulating substrates by MBE (molecular-beam epitaxy). A high-performance detector sensitive to radiation at the low fiber dispersion, 1.3- $\mu\text{m}$  wavelength was fabricated on a nonlattice matched, semi-insulating, GaAs substrate by growing a 0.5- $\mu\text{m}$ -thick undoped GaAs buffer layer followed by an intermediate 0.5- $\mu\text{m}$ -thick GaInAs layer with an indium concentration less than that needed to absorb 1.3- $\mu\text{m}$  radiation. This was then followed by the active GaInAs layer designed to absorb the 1.3- $\mu\text{m}$  radiation and a 500-angstrom layer which was graded back to GaAs at the surface. The metal fingers for the IMSM detector were then fabricated on the surface using a gold lift-off process. The graded gap layer serves two purposes: 1) to provide a high Schottky barrier at the surface making possible the IMSM detector and 2) to provide an electric field that repels electrons and holes from surface preventing their trapping there. Low-frequency gain, which usually limits the performance of IMSM detectors, was not observed. Responsivities of 0.5 A/W were measured at 1.3  $\mu\text{m}$  and a bandwidth of 3.2 GHz was estimated for the detector from the response to a 48-ps laser pulse at 0.8  $\mu\text{m}$ . 1 ref.

**096614 CURRENT NOISE IN N-TYPE  $\text{Al}_x\text{Ga}_{1-x}\text{As}$ .** Current noise in Si-doped  $\text{Al}_x\text{Ga}_{1-x}\text{As}$ , grown by means of M.O.V.P.E., was investigated in the frequency range 1 Hz-100 kHz and in the temperature range 80-340 K. The measured noise over and above thermal noise was found to depend quadratically on the applied electric field, which means that it was caused by resistivity fluctuations. The noise consisted typically of two types of components:  $1/f$  noise and one or two generation-recombination (g-r) components with Lorentzian-shaped frequency dependence. From the temperature dependence of the g-r noise relaxation times, it was possible to calculate the activation energies and capture cross sections of two different deep electron traps. (Author abstract) 7 refs.

**096616 INTEGRATED ALL-SILICON COLOR FILTERING ELEMENT WITH AN ENHANCED**

**WAVELENGTH TUNABILITY.** A method for applying the wavelength-dependent response of silicon photodiodes for the integration of an electronically tunable optical filtering element with the photodetector in silicon is presented. Previous sensors suffered from a limited tunable spectral range. Here, the filter tunability is extended by enhancing the long-wavelength tunability using an extra implantation for realizing a higher doped buffer layer underneath a shallow junction to reduce the built-in depletion layer. Also, an independent electronically programmable short-wavelength cutoff is introduced. The latter is based on the control of the surface space-charge region. The flexibility obtained allows the electronic shaping of clearly distinguishable responses using a single photodiode. 6 refs.

Wolffenbuttel, R.F. (Delft Univ of Technology, Neth). *IEEE Electron Device Lett* v 9 n 7 Jul 1988 p 337-339.

## Manufacture

**096617 GaInAs PIN PHOTODIODES GROWN ON SILICON SUBSTRATES FOR 1.55  $\mu\text{m}$  DETECTION.** We report GaInAs PIN photodiodes to be fabricated on silicon substrates. Superlattice buffer layers were used to accommodate the lattice parameter mismatch. Reverse leakage currents of approximately 70 nA at  $-1$  V bias were measured for 105  $\mu\text{m}$ -diam mesa diodes. The uncoated external quantum efficiency at a wavelength of 1.55  $\mu\text{m}$  was 30%. (Author abstract) 2 refs.

Hodson, P.D. (Plessey Research Caswell Ltd, Towcester, Engl); Bradley, R.R.; Riffat, J.R.; Joyce, T.B.; Wallis, R.H. *Electron Lett* v 23 n 20 Sep 24 1987 p 1094-1095.

## Materials

**096618 HIGH-SPEED FRONT-ILLUMINATED GaInAsP/InP pin PHOTODIODE.** We have developed a high-speed front-illuminated GaInAsP/InP pin photodiode for use at the optical wavelength of 1.3  $\mu\text{m}$ . The device is grown on an  $n^+$ -InP substrate and uses polyimide both as a passivation layer and as a bonding pad holder to reduce parasitic capacitance. An optoelectronic sampling measurement of the impulse response shows a pulsewidth (FWHM) of 28 ps. A 3 dB bandwidth in excess of 18 GHz has been achieved. (Author abstract) 7 refs.

Yi, M.B. (California Inst of Technology, Pasadena, CA, USA). *Electron Lett* v 24 n 8 Apr 1988 p 455-456.

**096619 DIELECTRICS FOR PASSIVATION OF PLANAR InP/InGaAs DIODES.** We have investigated dielectrics for passivating planar InP or InGaAs photodiodes thermally evaporated  $\text{Al}_2\text{O}_3$  and  $\text{SiO}_2$ , sputtered  $\text{Si}_3\text{N}_4$  and  $\text{SiO}_2$  and also  $\text{SiO}_2$  using chemical vapor deposition. The measured bulk and field-effect properties of all dielectrics excluding sputtered  $\text{SiO}_2$  were suitable for this application. In planar InGaAs diodes with Cd diffused or Mg implanted  $p^+$ -region a disordered dielectric/semiconductor surface led to high reverse current densities above 1 mA/cm<sup>2</sup>. In InP diodes with  $p^+$ -diffusion and dielectrics exhibiting positive flatband voltages, e.g.  $\text{Si}_3\text{N}_4$  and  $\text{Al}_2\text{O}_3$ , reverse current densities of 10  $\mu\text{A}/\text{cm}^2$  were measured probably caused by a slight inversion of the semiconductor surface. With a  $\text{SiO}_2$  or CVD- $\text{SiO}_2$  passivating layer on n-InP lowest leakage current densities (10 nA/cm<sup>2</sup>) were achieved. Very low dark-current planar photodiodes InP/InGaAsP/InGaAs have been fabricated using  $\text{SiO}_2$  passivation (30 nA/cm<sup>2</sup>). (Author abstract) 6 refs.

## Mathematical Models

**096620 NEW INFRARED AVALANCHE PHOTODIODE FOR LONG DISTANCE FIBER OPTIC**

**COMMUNICATION.** Theoretical studies are presented for the response characteristics and quantum efficiency of a new infrared avalanche photodiode (APD) for the 3-4  $\mu\text{m}$  wavelength range. The device structure is a photo-DOVATT (Double Velocity Avalanche Transit Time) made of  $\text{InAsSb}_{1-x}/\text{InAs}$ ,  $\text{InAsSb}_{1-x}$  being lattice matched to InAs. We expect it to be used in long distance fiber-optic communication. The calculated gain-bandwidth product is around 20 GHz and the calculated quantum efficiency is 75% near 3  $\mu\text{m}$  wavelength. (Edited author abstract) 8 refs.

Chakrabarti, P. (Birla Inst of Technology, Ranchi, India); Pal, B.B. *Solid State Electron* v 31 n 1 Jan 1988 p 1-3.

**096621 THEORY OF AVALANCHE DIODE HARMONIC OPTOELECTRONIC MIXER.** A simple empirical model is proposed for the multiplication factor of the avalanche photodiode (APD). Using this model closed-form expressions are derived for the conversion loss of APD optoelectronic mixers. The model is valid over a wider range of APD reverse-bias voltage. Using the new model, expressions are derived for the conversion loss of the APD harmonic optoelectronic mixing. (Edited author abstract) 4 refs.

Abuelma'atti, Muhammad Taher (Univ of Bahrain, Isa Town, Bahrain). *IEE Proc Part J* v 135 n 2 Apr 1988 p 183-186.

**096622 FIELD AND SPATIAL GEOMETRY DEPENDENCIES OF THE ELECTRON AND HOLE IONIZATION RATES IN GaAs/AlGaAs MULTIQUANTUM WELL APD'S.** Numerical calculations are presented of the electron and hole ionization rates in GaAs/AlGaAs multiquantum-well APDs (avalanche photodiodes) as a function of the applied electric field and the spatial geometries, i.e., the barrier- and well-layer widths, respectively. The model is calibrated to existing experimental data on bulk GaAs material and then extrapolated to the multiquantum well structure. It is found that at high electric field strengths the net ionization rate approaches the weighted average of the constituent bulk rates; the potential discontinuity is relatively insignificant. The potential discontinuity most greatly affects the electron ionization rate at low applied electric field strengths within a spatially symmetric structure. It is further determined that the electron-to-hole ionization rate ratio is greatest at low applied electric fields within a spatially symmetric structure with equal well and barrier widths. 38 refs.

## Microwaves

**096623 HIGH-SPEED InP/InGaAsP/InGaAs AVALANCHE PHOTODIODES GROWN BY CHEMICAL BEAM EPITAXY.** High-performance InP/InGaAsP/InGaAs avalanche photodiodes (APDs) grown by chemical beam epitaxy are described. These APDs exhibit low dark current (less than 50 nA at 90% of breakdown), good external quantum efficiency (greater than 90% at a wavelength of 1.3  $\mu\text{m}$ ), and high avalanche gain ( $\approx 40$ ). In the low-gain regime, bandwidths as high as 8 GHz have been achieved. At higher gains, a gain-bandwidth-limited response is observed; the gain-bandwidth product is 70 GHz. 24 refs.

Campbell, J.C. (AT&T Bell Lab, Holmdel, NJ, USA); Tsang, W.T.; Qua, G.J.; Johnson, B.C. *IEEE J Quantum Electron* v 24 n 3 Mar 1988 p 496-500.

## Millimeter Waves

**096624 TOP-ILLUMINATED InGaAs/InP P-I-N PHOTODIODES WITH A 3-DB BANDWIDTH IN EXCESS OF 26 GHz.** Top-illuminated InGaAs p-i-n photodiodes have been fabricated from metal organic vapor-phase epitaxy (MOVPE) material, grown on semi-insulating InP substrates. A flat frequency response to 26 GHz has been measured, which is the highest figure

yet reported for such devices. The predicted 3-dB bandwidth of these devices is 35 GHz. 6 refs.

## Noise

**096625 IMPROVED FIGURE OF MERIT FOR NOISE IN AVALANCHE PHOTODIODES.** We propose a new noise figure for avalanche photodiodes (APDs). This new noise figure overcomes the difficulty of estimating the internal multiplication and quantum efficiency in complex APD structures, such as III-V SAM APDs. Measurements of the new noise figure are presented for two commercial SAM APDs and we show theoretically that it represents a more complete figure of merit for comparing the performance of one APD with another, and with the ideal. (Author abstract) 3 refs.

Westbrook, L.D. (British Telecom Research Lab, Ipswich, Engl); MacBean, M.D.A.; Rodgers, P.M. *Electron Lett* v 24 n 14 Jul 7 1988 p 853-854.

**096626 Hg<sub>0.4</sub>CD<sub>0.6</sub>TE 1.55-μM AVALANCHE PHOTODIODE NOISE ANALYSIS IN THE VICINITY OF RESONANT IMPACT IONIZATION CONNECTED WITH THE SPIN-ORBIT SPLIT-OFF BAND.** The authors describe the electrical and optical characterization of three Hg<sub>1-x</sub>Cd<sub>x</sub>Te avalanche photodiodes manufactured using planar technology with composition parameter  $x$  near 0.6. This alloy composition leads to devices that are well suited for 1.55-μm detection. From the noise analysis under multiplication, the authors show the tight dependence of the ratio  $\beta/\alpha$  (of the hole and electron ionization coefficient, respectively) upon  $x$  and the ratio  $\Delta/E_g$  where  $\Delta$  is the spin-orbit splitting energy and  $E_g$  is the bandgap energy. It turns out that in these alloys around  $x = 0.6$ ,  $\Delta$  is very close to bandgap energy so  $\beta/\alpha$  reaches its maximum value. Owing to this property, which is characteristic of II-VI compounds, Hg<sub>1-x</sub>Cd<sub>x</sub>Te is a good candidate for 1.3-μm to 1.6-μm avalanche photodiodes. 12 refs.

Orsal, Bernard (Univ des Sciences et Technique du Languedoc, Fr); Alabedra, Robert; Valenza, Matteo; Lecoy, Gilles P.; Meslage, J.; Boisrobert, C.Y. *IEEE Trans Electron Devices* v 35 n 1 Jan 1988 p 101-107.

**096627 1/f NOISE IN SHORT n-p<sup>+</sup> DIFFUSION-CURRENT-DOMINATED (HgCd)Te AVALANCHE PHOTODIODES.** The observed 1/f noise from Hg<sub>0.56</sub>Cd<sub>0.44</sub>Te avalanche n<sup>+</sup>-n<sup>+</sup> p<sup>+</sup> photodiodes in the forward and reverse current shows the following regions: i) ohmic, ii) diffusion-dominated short diode, iii) series-resistance dominated, iv) diffusion-dominated short diode with reverse-bias-dependent length, and v) multiplication. The interpretation is based on Hooge's empirical 1/f noise formula and Kleinpenning's model for 1/f noise in short diodes. 24 refs.

**096629 HIGH RESPONSIVITY LONG-WAVELENGTH ( $\lambda = 10 \mu\text{M}$ ) GaAs/Al<sub>x</sub>Ga<sub>1-x</sub>As MUL-**

**TIQUANTUM WELL SUPERLATTICE TUNNELING DETECTOR.** The structure considered consists of 50 periods of 72-angstrom GaAs quantum wells doped  $n = 1.5 \times 10^{18} \text{ cm}^{-3}$  separated by Al<sub>0.38</sub>Ga<sub>0.62</sub>As barriers, with n<sup>+</sup> ohmic contacts on both sides. The quantum well is designed to contain only two bound states separated in energy by  $E_2 - E_1 = 124 \text{ meV}$  (corresponding to  $\lambda = 10 \mu\text{m}$ ). The ground state of one well aligns with the excited state of the neighboring well due to sequential resonant tunneling. This band alignment ensures that the incident infrared radiation is strongly absorbed by the intersubband resonance and photoexcites an electron. The electron then rapidly and efficiently tunnels out of the well and travels a hot-electron mean free path  $L$ , and thereby produces a large photocurrent. The responsivity  $R = 1.9 \text{ A/W}$ , while  $L = 4500 \text{ angstrom}$ . These results are a consequence of the thicker and higher tunneling barriers, which lowers the dark current and thus allows the use of higher bias voltages. These detectors have an advantageous narrow bandwidth ( $\Delta\lambda/\lambda = 10\%$ ) and an estimated high-speed response of over 10 GHz. These devices have been used to measure novel hot-electron superlattice transport physics. 3 refs.

## Oscillations

**096630 CURRENT OSCILLATIONS IN THE PLANAR BALLISTIC PHOTODIODE.** The possibility of current oscillations to occur in a thin layer of an intrinsic semiconductor at the charge carrier interband photogeneration was shown in previous papers. Current oscillations in a hypothetical semiconductor have been observed by simulation using the macroparticle technique. In the present paper the instability is considered and further results of investigation of the instability in a planar photodiode are presented. 3 refs.

**096632 DEVELOPMENT OF A P-I-N HgCdTe PHOTOMIXER FOR LASER HETERODYNE SPECTROMETRY.** An improved HgCdTe photomixer technology was demonstrated which employs a p-i-n photodiode structure. The i-region was near intrinsic n-type HgCdTe; the n-region was formed by B<sup>+</sup> ion implantation; and the p-region was formed either by a shallow Au diffusion or by a Pt Schottky barrier. Experimental devices in a back-side illuminated mesa diode configuration were fabricated, tested and delivered. The best photomixer was packaged in a 24-hour LN<sub>2</sub> dewar along with a cooled GaAs FET preamplifier. Testing was performed by mixing black-body radiation with a CO<sub>2</sub> laser beam and measuring the IF signal, noise, and signal-to-noise ratio in the GHz frequency range. Signal bandwidth for this photomixer was 1.3 GHz. The heterodyne noise equivalent power (NEP) was  $4.4 \times 10^{-20} \text{ W/Hz}$  out to 1 GHz, increasing to  $8.6 \times 10^{-20} \text{ W/Hz}$  at 2 GHz. Other photomixers delivered on this program had heterodyne NEPs at 1 GHz ranging from  $8 \times 10^{-20}$  to  $4.4 \times 10^{-19} \text{ W/Hz}$  and NEP bandwidths from 2 to 4 GHz. **096636 PHOTOCURRENTS IN p-n Si DIODES UNDER HIGH INTENSITY (PULSED-LASER) ILLUMINATION: QUANTUM YIELDS AND KINETIC EVALUATION.** The photoelectric response of p-n Si photodiodes under pulsed laser illumination (half width 10 ns) at 532 nm was studied as a function of dose, which was varied over 6 orders of magnitude. The photocurrent transients are dominated by a plateau-like feature due to the build up of space charge at the intensities used. Increasing bias voltage increases the height of the plateau and decreases its length. In the low-dose range the length of the transient increases linearly with dose and the collected charge reaches a constant value. At high doses considerable charge loss (decrease in quantum yields) is accompanied by a less than proportional increase of the transient lifetime. From model calculations the dose and voltage dependence of the quantum yield of charge collection is shown to be the result of competition between current flow and first and higher order recombination. The model calculations are consistent with experimental results. (Edited author abstract) 8 refs.

**096639 GAMMA RADIATION RESPONSE OF MWIR AND LWIR HgCdTe PHOTODIODES.** Results of an experimental investigation of the gamma radiation response of HgCdTe photodiodes are reported. The devices were fabricated in material grown by liquid-phase epitaxy; the p-n junctions were made by ion implantation and passivated with ZnS. The MWIR (medium-wave infrared) devices, tested at 120K, showed transient response in reasonable agreement with existing theory and total dose hardness greater than 1 Mrad(Si). The LWIR (long-wave infrared) detectors, tested at 40K, showed a degradation threshold at 10 Krad(H<sub>2</sub>O). This degradation is not a result of surface inversion resulting from charge trapping in the insulator. 3 refs.

**096641 RELIABILITY EVALUATION AND PREDICTION FOR SILICON PHOTODETECTORS.** The electrical parameters of silicon detectors were measured under various external influences (temperature cycling, humidity, salt atmosphere, etc.). The tests were designed and the data were analyzed by using the randomized block design method from the SAS software package. To estimate the lifetime of the detectors, an accelerated lifetime was implemented. Using plots of inspected interval data based on the maximum-likelihood technique (using the software package CENSOR), it was found that the Weibull distribution fit the lifetime test data. The CDF (cumulative distribution function) and the acceleration factor were calculated; the median lifetime of the silicon detector at room temperature was  $8.94 \times 10^6$  hours, and the 95% s-confidence interval was  $(7.16-10.6) \times 10^6$  hours. 25 refs.

**096642 RELIABILITY OF VAPOR-GROWN PLANAR In<sub>0.53</sub>Ga<sub>0.47</sub>As/InP P-I-N PHOTODIODES WITH VERY HIGH FAILURE ACTIVATION ENERGY.** The mean time to failure (MTTF) was measured for a statistically significant population of planar In<sub>0.53</sub>Ga<sub>0.47</sub>As/InP heterostructure p-i-n photodetectors at several elevated temperatures. The probability for failure is fit to a log-normal distribution, with the result that the width of the failure distribution is  $\sigma = 0.55 \pm 0.2$ , and is roughly independent of temperature. From the temperature dependence of MTTF data, it is found that the failure mechanism is thermally activated, with an activation energy of less than  $1.5 \pm 0.2$  eV measured in the temperature range of 170-250°C. This extrapolates to a MTTF of less than 0.1 failure in 10<sup>9</sup>h (or  $< 0.1$  FIT) at 70°C, indicating that such devices are useful for systems requiring extremely high reliable components, even if operated at elevated temperatures for significant time periods. This activation energy is the highest value reported for In<sub>0.53</sub>Ga<sub>0.47</sub>As/InP photodetectors, and is significantly higher than the energies of approximately 0.85 eV often suspected for these devices. 5 refs.

**Spectrum Analysis**

**096643 ANALYSIS OF THE R<sub>0A</sub> PRODUCT IN n<sup>+</sup>-p Hg<sub>1-x</sub>Cd<sub>x</sub>Te PHOTODIODES.** The influence of different junction current components (diffusion current for radiative and Auger 7 recombination mechanisms, tunneling and depletion layer currents) on the R<sub>0A</sub> product of n<sup>+</sup>-p-Hg<sub>1-x</sub>Cd<sub>x</sub>Te photodiodes is considered. The considerations are carried out for the 77-300 K temperature region and 1-15  $\mu$ m cutoff wavelength. Optimum doping concentrations in the p-type region of n<sup>+</sup>-p abrupt junctions are determined, taking into account the influence of the tunneling current and of a fixed surface charge density of the junction passivation layer. Results of calculations are compared with experimental data reported by many authors. An attempt is made to explain the discrepancy between theoretical calculations and experimental data. (Author abstract) 57 refs.

**Thermal Effects**

**096645 METHOD FOR STABILIZING THE MULTIPLICATION OF AN AVALANCHE PHOTODIODE.** In this paper we describe a new and effective method for stabilizing the working point and the multiplication factor of an avalanche photodiode. This method

sharply reduces the thermal instability of a photodetector. The method can be summarized as follows: a bias voltage with constant and varying components is applied to the diode. Since the avalanche multiplication factor M is a nonlinear function of the temperature and the bias voltage, a change in the temperature is accompanied by a change in the shape of the current signal from the diode, which is determined by the variable component of the bias voltage. As a result, the relation between the current signals from the diode averaged over the period and over the half-period of the alternating bias voltage can be used to identify the mismatch signal, which depends on the temperature. As this signal varies as a result of variations in the temperature and other factors, the constant bias voltage E and the amplitude (u<sub>M</sub>) of the alternating bias voltage change in equal degrees, until the value of the signal is restored. 3 refs.

**Electronic Properties**

**096646 MULTIPLE-STATE MEMORY CELL BASED ON THE RESONANT TUNNELING DIODE.** The device consists primarily of several molecular-beam-epitaxy (MBE)-grown GaAs/(AlGa)As resonant tunneling diodes connected in parallel. This device exhibits multiple peaks in the I-V characteristic. When a load resistor is connected, the circuit can be operated in a multiple stable mode. With this concept, implementation of three-state and four-state memory cells are made. In the three-state case the operating points at voltages V<sub>0</sub> = 0.27 V, V<sub>1</sub> = 0.42 V, and V<sub>2</sub> = 0.53 V represent the logic levels 0, 1, and 2. Similarly for the four-state memory cell the logic levels voltages are V<sub>0</sub> = 0.35 V, V<sub>1</sub> = 0.42 V, V<sub>2</sub> = 0.54 V, and V<sub>3</sub> = 0.59 V. A suggestion of an integrated device structure using this concept is also presented. 12 refs.

**096648 TUNNELING TIME THROUGH HETEROJUNCTION DOUBLE BARRIER DIODES.** The quantum mechanical tunneling time through a heterojunction double barrier diode (DBD) is calculated for all incident electron energies (on-resonance and off-resonance). The well-known result of Eisenbud and Wigner is used, and simple analytical results are obtained. The longest time delay occurs at the on-resonance incident energy due to the electron bouncing back-and-forth in the well region of a DBD. In addition to the exact result for the transmission coefficient and time delay, a Breit-Wigner resonant form is also used to model tunneling amplitude in the neighborhood of a resonance. The tunneling time delay consider-

ation indicates that the ultimate device response of DBDs utilizing GaAs-AlGaAs alloy system is in the sub-picosecond or picosecond regime. (Author abstract) 21 refs.

## Oscillations

**096649 FUNDAMENTAL OSCILLATIONS UP TO 200 GHz IN A RESONANT-TUNNELING DIODE.** The physical basis for these oscillations is the negative dynamic conductance (NDC) associated with the resonant tunneling of electrons through a quantum well bounded by two tunnel barriers. A key to achieving the present results was the use of thin (1.5 nm) AlAs barriers and moderate doping ( $N_D = 2 \times 10^{17} \text{ cm}^{-3}$ ) in the n-GaAs outside barriers. Another key to these results was the development of rectangular waveguide resonators capable of providing greater-than-unity circuit Q at frequencies where the terminal negative resistance of the diode is rapidly approaching zero. The diodes were mounted in the gap between the waveguide floor and the bottom of a post that protruded roughly halfway into the guide. The contact to the individual diodes was made with a whisker whose length (approx. 0.18 mm) was as short as practically possible to minimize parasitic inductance in the circuit. A WR-6 resonator yielded oscillations between 102 and 112 GHz with peak power of about 5  $\mu\text{W}$  in this band. The frequency tuning was accomplished primarily with bias voltage. A scaled-down version of this resonator in WR-3 waveguide achieved oscillations between 192 and 201 GHz, again tunable mostly by bias voltage. The peak power in this range was about 0.2  $\mu\text{W}$ .

## Applications

**096651 BRINGING SIMPLICITY TO ZENER BARRIERS.** Several hundred thousand shunt-diode safety barriers are installed every year to protect electrical circuits in hazardous areas; the number has been growing for a quarter of a century. Yet users frequently still have to select what they want from a confusing variety of options. Manufacturers still define barriers in electrical-component terms rather than by their instrumentation function, and offer more models than is necessary. This is not the case with the more recent isolating interface devices where users are presented with only a handful of designs, each carefully tailored for an application, and thus making selection simplicity itself. The author argues that seven modules now cover most needs.

**096654 RECTIFICATION PROPERTIES OF ASYMMETRICAL SUPERLATTICES.** A rectifying superlattice which can be used for detecting THz waves is proposed. The device is created by using an effective-mass superlattice in which the superlattice cycle is gradually changed. The operating principle is based on the fact that the quantum mechanical transmission coefficient with asymmetrical geometry is asymmetrical with respect to the applied voltage. The forward current is several orders in magnitude greater than the reverse current at a relatively low applied voltage. This feature is potentially useful for detecting and mixing small signals at THz frequencies. (Author abstract) 12 refs.

**096655 PHOTO-EPITAXY OF NARROW BAND GAP II-VI MATERIALS - THE WAY AHEAD.** The present status of photo-epitaxy in relation to narrow band gap II-VI materials is outlined. Epitaxial layers of  $\text{Cd}_x\text{Hg}_{1-x}\text{Te}$  and related binaries have been grown in the

temperature range 200°-300°C. Reaction mechanisms are discussed and include the Hg photosensitized decomposition of diethyltelluride, free radical mechanisms and the effect on alloy composition. The current problems of photo-epitaxy and the influences that solutions to these problems will have on future developments are considered. Greater tailoring of the precursors and u.v. wavelengths is anticipated and reaction paths selected for surface heterogeneous reactions. The future objective for photo-epitaxy of II-VI materials is to achieve in situ fabrication technology where the epitaxial growth only occurs on pre-selected areas of the substrate and is combined with other laser processing techniques. (Author abstract) 20 refs.

**096658 LIOUVILLE SPACE REVISITED: EXCITATION AND RELAXATION OF MULTIPLE-QUANTUM NUCLEAR SPIN COHERENCE IN DIPOLEAR SYSTEMS.** Dominant trends in the nuclear spin dynamics of large, strongly coupled systems are predicted using a model that treats coherence transfer as a multisite exchange process in Liouville space. The problem is broken into two parts. First, the formation of multiple-quantum coherences under a nonsecular Hamiltonian is examined for a system of N spin-1/2 nuclei. These coherences then are allowed to evolve under a secular Hamiltonian, during which time there occurs a redistribution into new multiple-spin modes. Throughout both phases, the system is driven to a steady state where most of the coherence is shared by modes involving approximately 75% of the spins. The effects of different initial distributions in Liouville space are investigated. (Author abstract) 8 refs.

**096659 AB INITIO EXPLANATION OF THE INCOMMENSURATE PHASE TRANSITION IN  $\text{BaMnF}_4$ .** Results of an a priori theoretical study of the origins of the incommensurate instability in  $\text{BaMnF}_4$  are presented. The most unstable vibrational mode lies at  $q_1 = (0.32, 0.5, 0.5)$  (in fractions of the reciprocal lattice vectors for the orthorhombic lattice), while the observed value is  $(0.392, 0.5, 0.5)$ . These findings are interpreted in terms of our previously introduced concept of an imperfect, or 'latent' symmetry which is extended into a general explanation of incommensurate behavior. A further possible consequence of this is that some strongly incommensurate systems could, in a specific and restricted sense, be novel states of matter. (Author abstract) 15 refs.

**096660 BRILLOUIN SCATTERING STUDY OF PHASE TRANSITIONS IN  $\text{TiInS}_2$ .** The temperature dependence of the elastic coefficients of  $\text{TiInS}_2$  has been investigated by Brillouin scattering measurements. For longitudinal phonons propagating in the (001) plane the variation of  $\Delta C_{11} \approx (T_c - T)$  was found below the ferroelectric transition point ( $T_c = 189$  K). For propagation perpendicular to the (001) plane ( $C_{33}$  mode) clear anomalies were observed at  $T = 213$  K and  $T = 195$  K. Between these temperatures the Brillouin peaks show broadening, which is attributed to a coupling between the acoustic mode and an overdamped mode. (Author abstract) 15 refs.

**096661 CYLINDRICAL QUANTUM WELL WITH POSITION DEPENDENT MASS.** Using the envelope function approximation and a one-band model, the cylindrical quantum well with position dependent mass problem is studied. The boundary conditions to be fulfilled by the radial wave functions are deduced. The transcendental equation for the energy levels, the normalized wave functions, and the confinement are obtained in the flat band approximation considering a sectionally constant mass profile. Also numerical results are given for the  $\text{GaAs-Al}_{0.32}\text{Ga}_{0.68}\text{As}$  cylindrical quantum well. (Author abstract) 15 refs.

**096662 THREE-BRANCH EXCITONIC POLARITONS IN DIRECT BAND GAP CUBIC SEMICONDUCTORS.** The transition is studied between a photon and 'heavy' and 'light' excitons in direct-band gap cubic semiconductors with a fourfold degenerated highest valence band at the center of the Brillouin zone. The transition matrix elements are calculated in the second-order approximation of the perturbation series with respect to a small constant proportional to the difference of the mass of the heavy and light holes. The algebraic equation determining the dispersion of the three-branch polaritons is derived. The spin structure of the wave functions of the corresponding excitons is established. (Author abstract) 7 refs.

**096663 ON PHOTOEMISSION FROM QUASI-ONE-DIMENSIONAL STRUCTURES OF NARROW-GAP SEMICONDUCTORS HAVING RECTANGULAR CROSS-SECTIONS.** An attempt is made to investigate for the first time the photoemission from quasi-one-dimensional (Q1D) structures of narrow-gap semiconductors having rectangular cross-sections, taking n-type  $\text{InSb}$  as a typical example. It is found that for Q1D structures having square cross-sections, the variation of the photocurrent density with the transverse dimensions is significantly influenced by the photo ener-

gies. For photon energies close to the electron affinity, the emission current exhibits an oscillatory character (with an increasing average) with the increasing transverse dimensions of the submicron structure. For photon energies significantly lower than the electron affinity, the emission could become forbidden over a narrow range of the transverse dimensions. 10 refs.

**096664 PHOTOELECTRON EMISSION AND SURFACE STATE BANDS IN III-V SEMICONDUCTORS.** The possibility of applying the method of external photoemission for detection of filled surface states in three III-V semiconductors is discussed. In the first part of the paper Kane's and Ballantyne's theories are presented. In the second part, experimentally obtained spectral distributions of derivatives of quantum yield  $Y'$  ( $\epsilon$ ) for  $\text{InSb}$  or  $\text{InAs}$  'real' and atomically clean surfaces are given, as well as those obtained with the use of theoretical Ballantyne's functions. Comparison of the peaks or 'shoulders' in these distributions led to conclusion, that photoemission yield curves reflect volume, electron features of crystals, and the observed peaks do not originate from surface states overlapping the valence bands. The similar result was obtained for  $\text{GaAs}$  crystals, however, in this case, the proportion of peak height in the respective figures does not give an obvious explanation (distribution  $Y'$  ( $\epsilon$ ) for  $\text{GaAs}$  with the surface orientation (100) and (110) were compared). The whole set of experimental data gave rise to conclude that, for the examined semiconductors the commonly used dependence  $Y'$  ( $\epsilon$ ) approx.  $N_0$  ( $\epsilon$ ) is improper. (Author abstract) 15 refs.

**096665 ON THE MECHANISMS OF PHOTOREFLECTANCE IN MULTIPLE QUANTUM WELLS.** Mechanisms of photoreflectance of MQW structures are studied. The photomodulation of the built-in surface electric field is analyzed. It is argued that in MQW structures unlike to bulk crystals the electric field does not result in a Franz-Keldysh-effect but rather in a Stark effect of subbands and excitons and a corresponding change of wavefunctions and oscillator strengths. The photoreflectance line shape is not of third derivative but of first derivative type in the case of MQW structures. Experimental photoreflectance spectra are reported which confirm these conclusions and allow the derivation of sublevel energies, broadening parameters, and exciton binding energies. (Author abstract) 17 refs.

**096666 DETERMINATION OF THE ELECTRON LIFETIME IN  $\text{P-CuInS}_2$  FROM A PHOTOVOLTAIC STUDY OF  $\text{In/p-CuInS}_2$  SCHOTTKY BARRIER DIODES.** The chalcopyrite  $\text{CuInS}_2$  semiconductor with the direct band gap  $E_g$  1.5 eV at  $T = 300$  K has been suggested as a useful material for electrooptical devices and photovoltaic conversion. The determination of the lifetime of minority carriers and their diffusion length is therefore important for analysis of the photovoltaic performance of this material. The results of a study of single crystals grown from the melt by the Bridgman method are presented. The crystals displayed p-type conductivity of about  $10^{-4} \Omega^{-1} \text{cm}^{-1}$  and hole mobility of about  $20 \text{ cm}^2 \text{V}^{-1} \text{s}^{-1}$ . From the typical capacitance-voltage characteristic of the diode the diffusion potential  $U_D = 0.34$  and width of the space charge layer  $w = 60 \text{ nm}$  were found at  $T = 300 \text{ K}$ . 12 refs.

**096667 DEVICE FOR CHARGE AND CURRENT RELAXATION SPECTROSCOPY OF LEVELS IN**

**SEMICONDUCTORS.** A device is described for determination of level parameters in semiconductors and semiconductor structures by charge and current relaxation spectroscopy. The device permits measurement of the relaxation of a leaking charge or a discharge current with a time constant of from approximately 1  $\mu\text{sec}$  to 10 sec. Level occupation is changed by a voltage or light pulse. The method permits determination of the energy state, capture cross section, and concentration profile of deep levels, the energy spectrum of surface states, and the concentration profile of uncompensated fine levels. The device allows study of specimens with  $R_c C_c \geq 1 \mu\text{sec}$ , where  $R_c$  is the leakage resistance and  $C_c$  is the equivalent capacitance of the specimen. (Author abstract) 9 refs.

**096668 NONCRYSTALLINE SEMICONDUCTORS.** This book incorporates 17 papers that focus on processes and materials on the insulating (or semiconducting) side of the Anderson transition. An attempt is made to give the reader a deeper understanding of noncrystalline semiconductors by contrasting the similarities and major differences exhibited by these material systems. The articles introduce the major concepts, describe our present understanding, and emphasize which questions remain unresolved and what needs to be done in the future. Comprehensive lists of references are included. Topics considered include: amorphous semiconductors, their optical, electronic and physical properties, magnetic effects, the Hatt effect, transport properties, vibrational spectra of amorphous solids, semiconductor devices, amorphous silicon, amorphous chalcogenides, amorphous group V semiconductors (P, As, Sb), oxide glasses, amorphous molecular solids, biological polymers, and impurity conduction in semiconductors. All papers are separately indexed and abstracted.

**096669 CRYSTALLINE SEMICONDUCTING MATERIALS AND DEVICES.** This book which contains 16 contributions by various authors, is concerned primarily with the fundamental theory underlying the physical and chemical properties of crystalline semiconductors. After basic introductory material on chemical bonding, electronic band structure, phonons, and electronic transport, some emphasis is placed on surface and interfacial properties, as well as effects of doping with a variety of impurities. Against the background, the use of such materials in device physics is examined and aspects of materials preparation are discussed. The level of presentation is suitable for postgraduate students and research workers in solid-state physics and chemistry, materials science, and electrical and electronic engineering. Topics considered include: amorphous silicon, ion implantation, annealing, optical-communication devices, theory of surface waves, space-charge layers at semiconductor interfaces, electronic structure of surface and interfaces, impurity bands, electronic states and structural properties of deep centers in semiconductors, shallow impurity states, localized phonon modes, electron transport, phonons, electronic band structure as well as bonds and bands in semiconducting materials. All papers are separately indexed and abstracted.

**096671 HOT ELECTRON MAGNETOPHONON RESONANCES IN CONDUCTION AND NOISE FOR A NONDEGENERATE SEMICONDUCTOR.**

The nonlinear transverse magnetoresistivity of conduction electrons subject to inelastic scatterings by longitudinal optical phonons in a non-degenerate semiconductor is determined using a balance equation approach. Magnetophonon resonances are examined in both, the linear and nonlinear transverse magnetoresistivities; and the electron temperature in an intense electric field is calculated as a function of the magnetic field, showing significant electron resonant cooling. The nonlinear current saturation in a high electric field is also studied, and is shown to be independent of the magnetic field. The thermal noise temperature for hot electrons at a nonzero bias is also examined, and exhibit its oscillatory behavior as a function of magnetic field. (Author abstract) 18 refs.

**096673 AB-INITIO DETERMINATIONS OF SEMICONDUCTOR SPIN-ORBIT SPLITTINGS FROM ASW.** We demonstrate that the spin-orbit splittings of the valence and conduction bands at the  $\Gamma$ , L and X symmetry points in the Brillouin zone of a series of IV-IV, III-V, II-VI and I-VII semiconductors can be obtained accurately, to within 15 percent, from the Augmented Spherical Wave (ASW) method. The expression required for the evaluation of the matrix elements of the spin-orbit operator within the ASW basis set is derived and discussed. Our results imply that the earlier experimental assignment of  $\Delta_0$  for AlSb and InP should be reconsidered. (Author abstract). 16 Refs.

**096674 LES SEMICONDUCTEURS II-VI PARTICULAIRES ET APPLICATIONS. [Group II-VI Semiconductors: Specific Features and Applications].** II-VI compounds form a particularly class of semiconductor materials owing to their specific physical properties. Yet, they can be compared with the III-V semiconductors (GaAs-InP) for their band gap engineering facilities. Up to now, their development was essentially bound with the needs of the infrared detection and imaging in the windows of atmospheric transmission from 8 to 12  $\mu\text{m}$

and 3 to 5  $\mu\text{m}$ , and more recently in the wavelength range which correspond to the optical fiber transmissions. High quality monocrystal are difficult to obtain with classical growing methods. However, with the aid of epitaxial technologies it is possible to realize new devices. The electronic structure of these materials reveals a few original characteristics in comparison with other semiconductor: large band gap range, metal/semiconductor transition, spin-orbit resonance, specific effects with magnetic ions in the crystal lattice etc. In this paper, the author describes some of the most significant properties of these materials, their technology and preparation and some of the most promising applications. (Edited author abstract). 53 Refs. In French.

**096686 ROLE OF DANGLING BONDS IN THE TRANSPORT AND RECOMBINATION OF a-Si:Ge:H ALLOYS.** Measurements are reported of the luminescence, time-of-flight photoconductivity and electron spin resonance (ESR) in a-Si:Ge:H alloys. In the

alloys it is found that the luminescence intensity varies with defect density according to a tunneling model similar to that in a-Si:H. However, the tunnelling distance decreases with Ge concentration up to about 30% and then increases. This nonmonotonic behavior is attributed to the additional chemical disorder of the alloys. Time-of-flight experiments confirm that the dangling bonds are the dominant deep trap in the alloys. We find that the capture cross-sections for electrons and holes are very similar to those measured in a-Si:H, and are independent of whether the trap is a Ge or Si dangling bond. (Author abstract) 20 refs.

**096687 A.C. CONDUCTION IN AMORPHOUS CHALCOGENIDE AND Pnictide SEMICONDUCTORS.** The various origins of a frequency-dependent conductivity in amorphous semiconductors are reviewed, stressing particularly recent advances and the influences that factors such as correlation and non-random spatial distributions of electrically active centres can have on the a.c. conductivity. A comprehensive survey is given of the experimental a.c. data for two types of amorphous semiconductor, namely chalcogenide and pnictide materials. It is concluded that the a.c. behaviour at intermediate to high temperatures is well accounted for by the correlated-barrier-hopping model, whereas the low-temperature behaviour is probably due to atomic tunneling. (Author abstract) 140 refs.

**096688 CALCULATION OF LOCALIZED-STATE ENERGY DISTRIBUTIONS FROM TRANSCIENT-PHOTO RESPONSE DATA.** Time-of-flight studies of carrier transport through films of an amorphous semiconductor may be used to explore the energy distribution of shallow localized states in such materials. In this paper, we describe a new and computationally straightforward procedure for this purpose. The effectiveness of both this and previous techniques is evaluated using computer-generated time-of-flight data for model semiconductor films having known energy distributions of localized states. The procedures are also assessed in relation to recent experimental data for electron transport in amorphous silicon. (Author abstract) 11 refs.

**096689 NOVEL DEPOSITION CONCEPT FOR AMORPHOUS SUPERLATTICES.** Cumulative layered structures of amorphous semiconductors have attracted much interest in recent years, as they make it possible to use quantum effects to improve semiconductor properties. There is, however, a serious disadvantage in using such superstructures in practical devices, because the conventional process requires mechanical alternation of source gases and evacuation of the system for each layer deposition. As an alternative to this inefficient physically controlled method, the authors have developed an efficient photochemically controlled method which facilitates the continuous deposition of various superlattices. In combination with two modes of excitation, at least one of which is operated in a pulsed mode, an appropriately selected pair of source gases accumulates continuously binary layers of amorphous semiconductors. As an example of verification of this novel process, an amorphous superlattice composed of an amorphous silicon carbide barrier layer and an amorphous silicon well layer was prepared from a mixture of disilane and carbon tetrafluoride. (Edited author abstract) 7 refs.

**096692 COMPUTER SIMULATION STUDIES OF RADIATION INDUCED AMORPHIZATION.** The molecular dynamics results reported here show the amorphization of a pure Lennard-Jones crystal under the introduction of point defects, either Frenkel pairs or isolated interstitials. The requirement of both critical concentration and introduction rate of the defects is evidenced, in agreement with laboratory results on metallic systems. The high value of the critical rate found is explained by the occurrence of a new migration mechanism, an athermal one, for the interacting interstitials, leading to a very fast elimination by clustering. (Author abstract) 13 refs.

**096693 METAL-SEMICONDUCTOR TRANSITION IN AMORPHOUS Si<sub>1-x</sub>C<sub>x</sub> FILMS: DETECTION OF THE TRANSITION BY ROOM-TEMPERATURE MEASUREMENTS.** The relation between  $\sigma$  and  $d\sigma/dT$  is studied at room-temperature. All samples investigated which show activated conduction at low temperatures fulfill  $\sigma(293\text{ K}) < 300\ \Omega^{-1}\text{ cm}^{-1}$ , whereas all samples with metallic conduction at low temperatures fulfill  $\sigma(293\text{ K}) > 440\ \Omega^{-1}$ . Within the regions 100 to 360  $\Omega^{-1}\text{ cm}^{-1}$  and 440 to 1400  $\Omega^{-1}\text{ cm}^{-1}$  nearly linear relations between  $\sigma$  and  $d\sigma/dT$  are observed. It appears likely that  $d\sigma/dT$  as a function of  $\sigma+0$  exhibits a knee at about 420  $\omega^{-1}\text{ cm}^{-1}$  indicating the presence of a sharp metal-semiconductor transition at room temperature. The experimental results confirm quantitatively a phenomenological model of  $\sigma(T, x)$  in the semiconducting region, which is developed mainly on the basis of low-temperature measurements in two preceding papers. (Edited author abstract) 13 refs.

**096694 ALLOYING EFFECTS ON THE OPTICAL ABSORPTION EDGE AND PHOTOCONDUCTANCE OF RF SPUTTERED a-Sn<sub>1-x</sub>Si<sub>x</sub>:H FILMS.** Hydrogenated amorphous Sn-Si alloy films were prepared by reactive co-sputtering at 220 and at 110°C. The tin content of the films varied between 0.3 and 4.7 at.%. The optical absorption and photoconductivity were measured as a function of wavelength and film composition. The energy gap, as evaluated from these measurements, de-

creases with increasing tin content, more strongly for samples prepared at the lower temperature. The photoconductance response varies strongly, by about three orders of magnitude, as the Sn concentration increases to 4.7 at.% and is quite different for the two kind of samples. (Edited author abstract) 20 refs.

**096696 PHYSICAL PROPERTIES OF AMORPHOUS MATERIALS, PROCEEDINGS OF A LECTURE SERIES.** The 14 papers in this volume are arranged in five parts. Part one, dealing with all aspects of the materials, can serve as a general introduction to the whole field. Part two is concerned with the structure of amorphous solids. Part three deals with the analysis of phonon modes in amorphous materials. The problem of electronic structure is the basis of both parts four and five. Part four is primarily concerned with the density of states available to electrons as they move through the disordered system. Part five is devoted to several aspects of nonequilibrium phenomena.

Adler, David (Ed.) (MIT, Cambridge, MA, USA); Schwartz, Brian B. (Ed.); Steele, Martin C. (Ed.). *Phys Prop of Amorphous Mater, Proc of a Lect Ser, Bloomfield Hills, MI, USA, 1982-1983* Publ by Plenum Press, New York, NY, USA & London, Engl, 1985 443p.

**096697 CHEMISTRY AND PHYSICS OF COVALENT AMORPHOUS SEMICONDUCTORS.** The author reviews the fundamentals of solid state physics adopting an approach in which periodicity is not fundamental and the theory of crystalline materials represents a subset of the general development. The current viewpoint is that the foremost consideration in any analysis of the properties of a particular material is the composition, which determines the chemistry and average coordination and thus, the local structure. The preparation conditions primarily affect the morphology but can also influence the local chemical bonding. The creation energy and effective correlation energy of the low-energy defects involve not only the nominal constituents but also the unintentional impurities. In addition, it is vital to analyze the surface and interface states as well as the space-charge conditions. Both chalcogenides and chalcogenides exhibit similar transient behavior, including dispersive transport, photoluminescence, photo-induced absorption, metastable phases, and photo-induced ESR. Many of these phenomena are now being observed and studied in crystalline semiconductors after having been first understood in amorphous phases. 167 refs.

Adler, David (MIT, Cambridge, MA, USA). *Phys Prop of Amorphous Mater, Proc of a Lect Ser, Bloomfield Hills, MI, USA, 1982-1983* Publ by Plenum Press, New York, NY, USA & London, Engl, 1985 p 5-103.

**096698 FUNDAMENTALS OF AMORPHOUS MATERIALS.** The author discusses the 'key' to making the nature of amorphous materials clear and to understanding their physical properties. First, there is an average coordination number which defines the structural integrity of the material and its gap and is determined only by the chemistry of the constituent atoms. This is called its normal structural bonding (NSB). Second, it is the deviations from the optimal coordination number, the deviant electronic configurations (DECs), that are essential to the understanding of the important phenomena in amorphous materials. It is these DECs which determine

the transport properties of amorphous materials and are responsible for the states in the gap. Third, there need not be corresponding crystal structures. The ability to design and synthesize a great variety of amorphous materials depends on the fact that many do not have corresponding crystal structures. The paper also describes new devices based on the application of these concepts. 115 refs.

Ovshinsky, Stanford R. (Energy Conversion Devices Inc, Troy, MI, USA). *Phys Prop of Amorphous Mater, Proc of a Lect Ser, Bloomfield Hills, MI, USA, 1982-1983* Publ by Plenum Press, New York, NY, USA & London, Engl, 1985 p 105-155.

**096699 STRUCTURAL STUDIES OF AMORPHOUS MATERIALS.** This paper is concerned with the progression from the initial studies of atomic arrangements in amorphous materials to those which have become possible recently as a result of the availability of synchrotron radiation. Regarding the last named, in principle it should be possible to use anomalous scattering to get the individual partial distribution functions. It should also be possible to determine atomic arrangements and their changes in real time for amorphous materials. Fractions of a second time scale are being evolved for EXAFS studies. There is reason to believe that these time-resolved studies will yield understanding of the rearrangements which take place as glasses go through the glass transition. The paper also includes a discussion on amorphous semiconductors. 24 refs.

**096700 PROBLEMS RELATING TO THE ELECTRONIC STRUCTURE OF AMORPHOUS SEMICONDUCTORS.** This paper deals with several problems related to the theory of amorphous semiconductors, some of which have remained unsolved despite the magnitude of the effort devoted to basic and applied research on these materials. The author reviews recent progress, attempts to identify the essential remaining difficulties, and summarizes new results. The topics covered are band tails, the Lloyd model, shallow impurity levels, deep levels, excitons, electronic transport, and optical absorption. 37 refs.

Cohen, Morrel H. (Exxon Research & Engineering Co, Annandale, NJ, USA). *Phys Prop of Amorphous Mater, Proc of a Lect Ser, Bloomfield Hills, MI, USA, 1982-1983* Publ by Plenum Press, New York, NY, USA & London, Engl, 1985 p 343-359.

**096701 NONEQUILIBRIUM TRANSPORT PROCESSES IN AMORPHOUS AND OTHER LOW CONDUCTIVITY MATERIALS.** The author discusses macroscopic transport theory. Microscopic transport theory is able to fix the constants of the material more or less arbitrarily. Of course, this is not actually correct; everything depends on everything else. Macroscopic transport theory, as such, does not know about this which means that models must be handled with care. There are two important time constants. One of them ( $\tau_0$ ) is the minority carrier lifetime which governs the rate at which a nonequilibrium concentration decays; it is called the carrier lifetime. The other ( $\tau_D$ ) is the dielectric relaxation time; it governs the decay of the charge, not the decay of free carrier concentration. Phenomena that are governed primarily by carrier concentration are controlled by  $\tau_0$ ; phenomena which are primarily governed by space charge are controlled by  $\tau_D$ . 20 refs.

Henisch, Heinz K. (Pennsylvania State Univ, University Park, PA, USA). *Phys Prop of Amorphous Mater, Proc of a Lect Ser, Bloomfield Hills, MI, USA, 1982-1983* Publ by Plenum Press, New York, NY, USA & London, Engl, 1985 p 361-379.

**096702 PECULIAR MOTION OF ELECTRONS IN AMORPHOUS SEMICONDUCTORS.** An introduction summarizes the basic concepts which are used to describe the electronic properties of amorphous semicon-

ductors. The next section discusses some experiments which have been useful in testing these ideas and providing detailed information about amorphous semiconductors. These experiments concern a time of flight technique in transient photoconductivity and a multiple trapping model of dispersive transport. 8 refs.

**096703 BEHAVIOR OF PHOTOCONDUCTIVITY DURING THE APPROACH TO STEADY STATE IN AMORPHOUS SEMICONDUCTORS.** The behavior of photoconductivity during the approach towards steady state in amorphous semiconductors is examined based on the rate equations governing both the occupancy function of localized states and the density of excess free carriers in the extended states. Assuming a shape for the time-dependent trap occupancy function and in an exponential distribution of localized states, under the consideration of recombination term as a perturbation, a power-series solution to an approximate form of the nonlinear multiple-trapping problem including diffusion-limited bimolecular recombination is obtained. The calculated photocurrent is predicted to rise as  $t^\alpha$  at an early stage of photoexcitation, where  $\alpha$  is a dispersive parameter, then to exceed the steady state value by a factor before settling down to the steady level. (Author abstract) 11 refs.

Gu, Benyuan (Acad Sinica, Beijing, China). *Solid State Commun* v 60 n 11 Dec 1986 p 889-892.

**096704 DEPLETION-DISCHARGE TRANSIENT SPECTROSCOPY: DIRECT DETERMINATION OF THE DENSITY OF DEEP EMISSION STATES IN AMORPHOUS SEMICONDUCTORS.** An analysis was made of the depletion-discharge process observed in amorphous semiconductors, where the dark decay of the surface potential  $V$  was caused by a sweep out from the bulk of only one sign of the charge carriers thermally generated from deep states in the bulk and a simultaneously progressive formation of the space charge of the opposite sign. It is shown that the distribution of the density of deep emission states can be directly determined from a plot of  $t|dV/dt|$  for  $t < t_d$  ( $t_d$ : the depletion time) and  $t[d(1/V)/dt]$  for  $t > t_d$  vs  $\ln(t)$  using a deconvolution technique. (Author abstract) 12 refs.

**096706 SEMICONDUCTING AMORPHOUS FILM CONTAINING CARBON NITROGEN AND BORON.** A semiconductor amorphous film containing carbon, nitrogen, and boron was deposited on a variety of substrates through the pyrolysis, in a closed system, of a borazine derivative. Physical and physicochemical characterization revealed a carbonaceous material having an amorphous matrix similar to vitreous carbon, but denser, with embedded crystallites of boron nitride. The film is highly reflective, adherent, hard, and behaves as a narrow band semiconductor. The bandgap is susceptible to modification by chemical treatment. (Author abstract) 18 refs.

Maya, Leon (Oak Ridge Natl Lab, Oak Ridge, TN, USA). *J Electrochem Soc* v 135 n 5 May 1988 p 1278-1281.

**096707 ELECTRONIC PROPERTIES OF AMORPHOUS SEMICONDUCTORS.** We review our understanding of the electronic states in amorphous semiconductors. The materials upon which we concentrate are the group IV semiconductors and Se. Experimental probes of the density of states and theoretical interpretations are reported. 58 refs.

Weaire, D.; O'Reilly, E. *Noncryst Semicond* Publ by CRC Press Inc, Boca Raton, FL, USA, 1987 v 1, p 1-17.

**096708 LOCALIZED STATES IN THE BAND GAP OF AMORPHOUS SEMICONDUCTORS.** Transient photoconductivity (TPC), transient photoinduced optical absorption (PA), and transient photoluminescence (PL) are considered. Using TPC it has become possible to map out the density of states in the band-tails. The transient optical experiments as well as TPC provide information about deeper gap states arising from defects. The current model for the important defects in chalcogenide glasses and information about defect states coming from TPC, PA, and PL is reviewed. It is shown how the defect and band-tail states interact in some of the experiments. 54 refs.

Kastner, M.A. *Noncryst Semicond* Publ by CRC Press Inc, Boca Raton, FL, USA, 1987 p 45-67.

**096709 TETRAHEDRALLY BONDED AMORPHOUS SEMICONDUCTORS.** This review concentrates on amorphous Ge and Si. The author discusses the different methods of preparation and describes the relaxation and crystallization processes. Structure studies of both local atomic arrangement and medium-range inhomogeneities are presented. Vibrational and electronic densities of states in the presence of disorder, which are related to the intrinsic network characteristics with little influence of defects, are dealt with. Optical and transport properties, which are largely influenced by the presence of defects, and are dependent on preparation conditions are considered, along with the nature of the defects and their associated localized states. 291 refs.

Theye, Marie-Luce. *Noncryst Semicond* Publ by CRC Press Inc, Boca Raton, FL, USA, 1987 v 2, p 1-51.

**096710 AMORPHOUS CHALCOGENIDES.** The term —chalcogenides—, as used here, comprises the elements S, Se, Te as well as their compounds. We restrict ourselves to a few members of the family such as Se and the As chalcogenides which have received the greatest attention either because they have found applications in xerography or because of interesting scientific phenomena. Structure and structural defects, optical and electrical properties, recombination of excess carriers, and interaction with light are dealt with. 142 refs.

Weiser, K. *Noncryst Semicond* Publ by CRC Press Inc, Boca Raton, FL, USA, 1987 p 97-131.

**096711 AMORPHOUS GROUP V SEMICONDUCTORS: P, As, AND Sb.** The group V amorphous semiconductors of P, As, and Sb exhibit a number of special characteristics that differentiate them from other elemental amorphous systems. Of particular interest is the strong evidence for intermediate range structural order, particularly in a-P and a-As. Emphasis is placed on recent studies on a-P, particularly with a focus on structural, vibrational, and optical properties. The special aspect of variable order in the group V systems is further emphasized. The presence of intermediate range order in amorphous group V systems makes these systems of interest to parallel studies in Ge and As chalcogenide systems. 78 refs.

Lannin, Jeffrey S. *Noncryst Semicond* Publ by CRC Press Inc, Boca Raton, FL, USA, 1987 p 133-160.

**096712 RAMAN RESEARCH OF AMORPHOUS SEMICONDUCTOR MODULATED STRUCTURE.** Raman research of amorphous semiconductor modulated structure is introduced, which gives a certain quantity of angle disorder and the method of determining the size of crystallite from the frequency shift of TO-like peak. Emphasis is placed on the frequency spectra of modulated

structures and some clear and definite conclusions are drawn. (Edited author abstract) In Chinese. 3 refs.

**096713 PHASE SHIFT ANALYSIS OF MODULATED PHOTOCURRENT: DETERMINATION OF THE ENERGY SCALE.** For the determination of the density of states in the mobility gap of amorphous semiconductors using the —phase shift analysis of modulated photocurrent— this paper suggests that making use of the magnitude of the induced photocurrent helps to remove arbitrariness in the energy scale. The working equations for the density of states and the corresponding energy position are expressed in terms of the intensity of the photocurrent. A simulation is made for a specific distribution, to investigate the validity of the procedure. The results show that the profile of the energetic distribution of localized states and the exact energy position of each state are consistent with the original distribution considered. (Author abstract) 10 refs.

**096715 STRUCTURE OF AMORPHOUS SEMICONDUCTORS.** The structure of several amorphous semiconductors is now known with considerable precision on a scale of 3-1000 Angstrom. Crucial experiments in this area are discussed. (Edited author abstract) 13 refs.

Phillips, J.C. (AT&T Bell Lab, Murray Hill, NJ, USA). *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 257-259.

**096716 HIGH BRILLIANCE X-RAY SOURCES AND THE STUDY OF AMORPHOUS MATERIALS.** The impact of the availability of x-ray synchrotron radiation on the study of atomic arrangements in amorphous materials was reviewed previously. Since that time, it has become apparent that orders of magnitude increases in the x-ray spectral brilliance will soon become available as a result of the use of undulators on the 16 GeV storage ring PEP at Stanford University and proposed 6-8 GeV storage rings. In this paper, the author reviews the new characteristics which the radiation will have, relative to that obtained from bending magnets and wigglers. He discusses the manner in which the studies of atomic arrangements may be expected to be affected by these changes. 7 refs.

Bienenstock, Arthur (Stanford Univ, Stanford, CA, USA). *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 269-272.

**096717 X-RAY ABSORPTION STUDIES OF AMORPHOUS ARSENIC CHALCOGENIDE SEMICONDUCTORS.** An important family of amorphous (a-) semiconductors is chosen to demonstrate current state-of-the-art techniques in x-ray absorption spectroscopy (XAS). The authors review recent developments in XAS methods before discussing applications to amorphous arsenic trisulfide (a-As<sub>2</sub>S<sub>3</sub>) and related systems. Investigations of XAS on a-As<sub>2</sub>S<sub>3</sub> are shown to result in: an ability to use XAS to measure bond strengths; a better understanding of reversible photo-darkening; and development of a technique for crystallizing pure As<sub>2</sub>S<sub>3</sub> from the bulk glass. (Edited author abstract) 16 refs.

Sayers, D.E. (North Carolina State Univ, Raleigh, NC, USA); Yang, C.Y.; Paesler, M.A. *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 273-282.

**096718 ELECTRICAL CONDUCTIVITY OF NON-HYDROGENATED AMORPHOUS TETRACORDINATED SEMICONDUCTORS.** The authors present the results of conductivity measurements as a function of temperature performed on a series of flash-evaporated a-III-V compounds, in comparison with those previously obtained on evaporated a-Ge. All samples have been deposited under controlled conditions and their global composition has been checked. They have also been studied by other methods, which brings additional information for the analysis of the data. Yet, the dispersion of the results remains too large, and the information appears too restricted, for proposing a unified model of transport in a-compounds. The authors, however, show that one must call for conduction mechanisms different from those admitted in a-Ge and a-Si, because the localized states in the pseudo-gap are not distributed in the same way. 26 refs.

Theye, Marie-Luce (CNRS, Paris, Fr); Gheorghiu, Adriana; Rappeneau, Therese; Udron, Dominique. *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 489-497.

**096719 CARRIER RECOMBINATION KINETICS IN AMORPHOUS DOPING SUPERLATTICES.** Research activities on nipi structures are reported, along with conductivity measurements as a function of layer thickness. The salient features of these measurements are discussed. The authors consider the kinetics of photocarrier recombination in nipi samples below 20 K, as well as persistent photoconductivity. 15 refs.

Ley, L. (Max-Planck-Inst fuer Festkoerperforschung, Stuttgart, West Ger); Hundhausen, M. *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 551-561.

**096720 MATERIAL DESIGN BY STRUCTURAL MODULATION OF AMORPHOUS SEMICONDUCTORS.** A new concept in material design based on the structural modulation of amorphous semiconductors is described. Near-infrared sensitive photoconductors with high photoresponse are designed by employing stacked multilayers of a-Si:H(F)/a-SiGe<sub>x</sub>H(F) prepared by hydrogen radical enhanced chemical vapor deposition. Measurements of conductivity perpendicular to the layers have indicated that structural modulation suppresses dark conductivity without sacrificing photoconductivity. Studies of transient photocurrent suggest the presence of artificially-produced shallow trapping states in the modulated structure. (Author abstract) 17 refs.

Oda, S. (Tokyo Inst of Technology, Yokohama, Jpn); Shirai, H.; Tanabe, A.; Hanna, J.; Shimizu, I. *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 563-575.

**096721 THEORY OF COVALENT AMORPHOUS SEMICONDUCTORS.** Amorphous-semiconductor theory has undergone a continual evolution over the past 20 years. A modern view is discussed. (Edited author abstract) 34 refs.

Adler, David (MIT, Cambridge, MA, USA). *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 673-680.

**096722 LOCALIZATION EFFECTS IN AMORPHOUS SEMICONDUCTORS.** On the basis of recently developed theories of transport and optical properties of amorphous semiconductors the question is discussed whether localization effects manifest themselves in the transport and optical data of these materials. It is argued that strong static disorder is responsible for the fact that quite generally  $Q_0 \approx 10$ , where  $Q_0$  is the intercept of

$Q = \ln(\sigma/\Omega cm) + |eS/k|$  vs.  $T^{-1}$ . Optical properties, matrix elements in particular, are hardly influenced by localization. (Edited author abstract) 20 refs.

Dersch, U. (Philipps-Univ, Marburg, West Ger); Thomas, P. *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 697-704.

**096723 BAND-EDGE CONDUCTION IN AMORPHOUS SEMICONDUCTORS.** Experiments have shown that the conduction process near the band edges of amorphous semiconductors differs from that in crystals. Three possible explanations for the anomalies have been proposed: long-range potential fluctuations, hopping in band tails, and polaron formation. The transport energy description is used to show how band-tail hopping may cause the anomalous transport. Transient measurements provide additional evidence for hopping. In the band-tail-hopping regime, the mobility edge plays no direct role in transport phenomena. (Edited author abstract) 41 refs.

Monroe, Don (AT&T Bell Lab, Murray Hill, NJ, USA). *Disord Semicond* Publ by Plenum Press, New York, NY, USA and London, Engl, 1987 p 705-712.

**096724 MECHANICAL STRESS IN THE CRYSTALLIZATION PROCESS OF AMORPHOUS SEMICONDUCTORS BY PULSE ACTION.** Rapid heating of amorphous materials by pulse annealing gives the possibility of avoiding solid phase ordering processes and of exceeding the temperature  $T_{AM}$  at which melting, supercooled melt formation, and crystallization take place. The high rate of cooling gives a glass-like state. The kinetics of these processes allows for crystal nucleation and growth. The mechanical stress energy decreases the time of liquid and crystalline nucleus formation and accelerates the beginning of crystallization. 12 refs.

Aleksandrov, L.N. (Acad of Sciences of the USSR, Novosibirsk, USSR). *Phys Status Solidi A* v 106 n 2 Apr 1988 p k135-k138.

**096725 THEORETICAL CALCULATION OF THE EFFECTIVE CORRELATION ENERGY OF THE HYDROGENATED AMORPHOUS GERMANIUM DANGLING BOND BY THE SELF-CONSISTENT-FIELD X-ALPHA SCATTERED-WAVE METHOD AND COMPARISON OF RESULTS BETWEEN A-Si:H AND A-Ge:H.** The authors have performed the self-consistent-field x-alpha scattered-wave (SCF-X $\alpha$ -SW) calculations on a 13-atom cluster Ge $4$ (sat) $9$  which is used to model the dangling bond defect center in hydrogenated amorphous germanium (a-Ge:H). The transition state concept of the SCF-X $\alpha$ -SW method was applied to the model cluster to determine the effective correlation energy  $U_{eff}$ . The effects of local atomic relaxations around the positively ( $T_3^+$ ) and negatively ( $T_3^-$ ) charged dangling bond defect centers were examined. The results yield a positive effective correlation energy (0.027 eV). Also a comparison of the results for the Si and Ge dangling bonds, so made, and its implications are discussed. (Edited author abstract). 11 refs.

Lo, C.F.; Adler, D.; Johnson, K.H. *J Non Cryst Solids* v 103 n 1 6(II) 1988 p 3-8.

**096726 CONDUCTION BAND IN NON-CRYSTALLINE SEMICONDUCTORS.** Following investigations by P. Thomas and co-workers, the energy of the current path in the conduction band of noncrystalline semiconductors and its relation to the calculated mobility edge is investigated. Delocalization is assumed to occur when  $L_i < \xi$ , where  $\xi$  is the localization length and  $L_i$  the inelastic diffusion length. For a non-degenerate gas we believe that localization is never complete, in contrast to the situation in metals. Both amorphous silicon and impurity bands in crystalline materials are discussed. The relationship of the pre-exponential factor in the conductivity to the predictions of scaling theory is investigated. No evidence is found for any error in the latter. (Author abstract). 74 refs.

Mott, N.F. (Univ of Cambridge, Cambridge, Engl). *Philos Mag B* v 58 n 4 Oct 1988 p 369-384.

**096727 STRUCTURAL STUDY BY ELECTRON DIFFRACTION ON AMORPHOUS Se $_{100-x}Bi_x$  FILMS.** Amorphous and homogeneous thin films of the Se $_{100-x}Bi_x$  system were obtained by a controlled co-evaporation technique in the region dilute in Bi ( $x < 5$ ). A structural study has been carried out on the basis of electron diffraction experiments. The maximum entropy method was used to minimize the effects of truncation of data ( $S < 8$  angstrom $^{-1}$ ). Details of the distribution functions in the direct space are analyzed in relation to that of pure selenium. Problems of the real coordination of Bi in these alloys and the role played by Bi as a modifier element in the amorphous matrix of selenium. (Edited author abstract). 38 refs.

Munoz, A. (Dep de Fisica de la Materia Condensada, Seville, Spain); Cumbreira, F.L.; Marquez, R. *Mater Lett* v 7 n 4 Oct 1988 p 138-142.

**096728 THEORY OF AMORPHOUS SEMICONDUCTORS.** A thermodynamic view of the structure of covalent amorphous semiconductors is presented in which local configurations of higher free energy that are accessible at high temperatures are frozen in below the glass transition temperature. It is shown how this leads to exponential band tails, defect states, and the possibility of doping. Given the resulting density of states, the possible mechanisms of electronic transport are analyzed. (Author abstract) 16 refs.

Adler, David (MIT, Cambridge, MA, USA). *Key Eng Mater* v 13 pt 1 1987, Int Conf on Met and Semicond Glasses (MSG-86), Hyderabad, India, Dec 16-20 1986 p 11-17.

**096729 MULTILAYERED AMORPHOUS SEMICONDUCTORS: PERIODIC AND QUASIPERIODIC SUPERLATTICES.** A brief description of the electronic properties of amorphous superlattices is presented within a comparison with their crystalline counterparts. Some examples are given to demonstrate that these new materials, beyond their proper peculiarities related to the multilayered structures, provide possibilities to obtain information about properties of amorphous bulk materials. Emphasis is put on the investigation of thermal relaxation, kinetics and mechanism of mixing operations as evidenced in diffraction approaches. Quasiperiodic superlattices, with layers deposited in a Fibonacci sequence, are also mentioned in relation with the understanding of the usual physical properties of true quasicrystals. (Author abstracted) 58 refs.

**096730 ELECTRONIC TRANSPORT IN AMORPHOUS CHALCOGENIDE SEMICONDUCTORS.** Charge transport in the relatively simple amorphous chalcogenide semiconductors such as Se and As $_2$ Se $_3$  most likely involves trap-limited processes. Carriers migrate via extended states or via states at or close to the mobility edges,  $E_c$  and  $E_v$ . The evidence from a variety of experiments is consistent with the view that the traps which limit carrier mobilities are located at relatively well-defined energies within the mobility gap, and that these traps originate from structurally-related electronic defects characteristics of various bonding abnormalities associated with the chemistry of chalcogenide elements and compounds. 51 refs.

**096731 THEORETICAL STUDIES OF OPTICAL ABSORPTION IN AMORPHOUS SEMICONDUCTORS.** Optical properties and matrix element effects of amorphous semiconductors are studied theoretically on the basis of a simple two-band model. We consider the tight-binding-Hamiltonian of Abe and Toyozawa including short ranged disorder. Two different approaches to

calculate the imaginary part of the dielectric constant  $\epsilon_2(\omega)$  are used. Both allow to go in a systematic manner beyond the zeroth order for  $\epsilon_2$  which is the convoluted density of States. (Edited author abstract) 4 refs.

**096732 ATOM ARRANGEMENT IN III-V QUATERNARY ALLOY SEMICONDUCTORS OF (ABCD) TYPE.** The nonrandomness in atom arrangement has been estimated for III-V quaternary alloys of (ABC)D type through a thermodynamical analysis. As in ternary alloys, the strain energy is considered to be the mixing enthalpy. Calculations were carried out for (In-GaAl)As and Ga(SbAsP), and the results are represented in terms of short-range order parameters of second-nearest pairs. The number of pairs increases compared with a random arrangement if composed of larger and smaller atoms than the average; however, the number of pairs of larger or smaller atoms decreases. When the lattice constant of a constituent binary compound coincides with that of an alloy, there appears in the alloy a preference for compound clustering. The results are compared with those for ternary alloys. (Author abstract) 26 refs.

## Applications

**096735 GaInAs MISFETS SHOW PROMISE IN POWER APPLICATIONS.** Metal-insulator-semiconductor FETs (MISFETs) fabricated from GaInAs have characteristics that make them potentially superior in some respects to GaAs MESFETs when used in power amplifiers. For this reason, researchers are making concentrated efforts to produce devices that demonstrate their performance potential. Insulated-gate FET technology unlocks the potential of this new material for high-frequency devices. 18 refs.

## Calculations

**096736 SCATTERING OF EXCITONS BY EXCITONS IN SEMICONDUCTING QUANTUM WELL STRUCTURES.** We have theoretically investigated the scattering of excitons by excitons in a two-dimensional semiconducting quantum well system. The scattering cross sections have been calculated using the Born approximation for both the elastic and inelastic scattering of the excitons by excitons. The threshold for inelastic scattering is increased over the value in a bulk semiconductor because of the enhancement of the exciton binding energy by its confinement. The behavior of the scattering cross section as a function of the energy of relative motion of the excitons is different than in the bulk and the cross section is a more sensitive function of the ratio of the electron and hole masses than in the bulk. (Author abstract) 31 refs.

**096738 SCATTERING OF EXCITONS BY FREE CARRIERS IN SEMICONDUCTING QUANTUM WELL STRUCTURES.** We have theoretically investigated the scattering of excitons by free electrons and holes in a two-dimensional semiconducting quantum well system. The scattering cross-sections have been calculated using the Born approximation for both the elastic and inelastic scattering of the excitons by the free carriers. The threshold for inelastic scattering is increased over the value in a bulk semiconductor because of the enhancement of the exciton binding energy by its confinement. The behavior of the scattering cross-section as a function of the energy of relative motion of the free carriers and the excitons is different than in the bulk and the cross-section is a more sensitive function of the ratio of the electron and hole masses than in the bulk. **096739 TWO-PARTICLE MONTE-CARLO METHOD FOR WARM ELECTRONS IN A HIGH-FREQUENCY ELECTRIC FIELD.** A two-particle Monte-Carlo method for the numerical simulation of the nonhomogeneous kinetic equations useful for the treatment of warm electron properties in the case of ac fields is given. The method is based on the solution of the Green function equation by the Monte-Carlo Technique. The electric field time dependence is taken into account by the simulation of the motion of particles with variable weights. Making use of the proposed method the frequency dependence of the nonlinearity coefficient for p-Ge is calculated. (Author abstract) 8 refs.

**096740 BAND-TO-BAND RECOMBINATION IN  $Ga_xIn_{1-x}Sb$ .** The carrier lifetimes in  $Ga_xIn_{1-x}Sb$  for radiative and Auger recombination are calculated for the temperature range 77-300 K and the composition range  $0 \leq x \leq 1$ . The possible band-to-band Auger recombination mechanisms in direct-gap semiconductors are investigated. The Auger rates are calculated, including Boltzmann Statistics and nonparabolic bands, using the Kane-band model. In the low temperature range, for lightly doped material, the carrier lifetime is determined by radiative recombination. At higher temperatures the CHCC process is dominant in n-type  $Ga_xIn_{1-x}Sb$  but in p-type material the CHLH process is dominant. The influence of CHSH processes on the carrier lifetime is appreciable in p-type  $GaSb$ . The calculations are compared with experimental data reported by other authors. (Author abstract) 42 refs.

**096741 INFLUENCE OF MINORITY CARRIER DIFFUSION LENGTH IN DETERMINING THE EFFECTS OF BASE LAYER THICKNESS OF AN  $n^+p$  SILICON SOLAR CELL AND A BSF CELL BY NUMERICAL ANALYSIS.** A systematic study on the performance of a diffused cell with base width has been carried out for three different minority carrier lifetimes in the base. The numerical analysis shows that the diode is mainly controlled by the diffusion of minority carriers in the base rather than the recombination process. It is sufficient to choose the thickness of the device to be about its minority carrier diffusion length. The reflection of the charge carriers by the back-surface-field in the BSF cell enhances the performance of the conventional diffused cell to a greater extent. Again the peak efficiency with thickness in BSF cell efficiency shows that it is sufficient to have base thickness half of its minority carrier diffusion length. 10 refs

**096742 INTERACTION OF A LOCALIZED SPIN MOMENT WITH PHONONS DUE TO THE EXCHANGE SCATTERING OF VIRTUAL CARRIERS IN SEMICONDUCTORS.** A new theory of the spin-lattice interaction mechanism is developed for localized spins in semiconductors. In this mechanism, the coupling with phonons results from exchange scattering on a localized spin of the electron-hole pairs accompanying the phonons. The process leads to a relaxation flip of the localized spin, provided the intermediate-state carrier spins are flipped by spin-orbit interaction. A detailed analysis of the mechanism is carried out in the approximation of the isotropic band structure of the semiconductor and the deformation electron-phonon interactions. The experimental manifestations of the mechanism are discussed. (Author abstract) 15 refs.

**096746 ON THE DIFFUSIVITY-MOBILITY RATIO OF THE CARRIERS IN n-CHANNEL INVERSION LAYERS ON TERNARY CHALCOPRYTE SEMICONDUCTORS.** An attempt is made to study the Einstein relations for the diffusivity-mobility ratios of the carriers in n-channel inversion layers on ternary chalcopryte semiconductors under both weak and strong electric field limits, taking n-channel inversion layers on  $CdGeAs_2$  as an example. It is found, on the basis of newly derived 2D  $E-k_x$  dispersion relations of the conduction electrons for both the limits by considering the various types of anisotropies in the energy band, that the ratios increase with increasing surface electric fields for both the limits and the theoretical results are in qualitative agreement with the suggested experimental method of determining the Einstein relation in degenerate semiconductors having arbitrary dispersion law. The corresponding well-known results for isotropic two-band Kane model are also obtained from the expressions derived. (Author abstract) 32 refs.

**096747 OPTICAL DAMPING CONSTANT DUE TO FREE CARRIERS IN NARROW GAP SEMICONDUCTORS.** Far infrared reflection spectra of narrow gap semiconductors ( $HgSe$ ,  $Zn_xHg_{1-x}Se$  and  $Cd_xHg_{1-x}Se$ ) are measured by a Fourier transform system in the range of 20 to 500  $cm^{-1}$  at 5 K. The spectra of these materials are analyzed by using the dynamic dielectric function as a sum of interband and intraband transitions and phonon contributions. Damping constants of free carriers are estimated from best fitting with experimental reflectivity curves. The frequency dependence of the damping constant for  $HgSe$  shows the Drude type in lower

frequency than the plasma frequency. That in higher than the plasma frequency is explained well by the impurity scattering including single and collective excitations and the effect of the electron-LO phonon polar coupling. The dependence of the damping constant on the frequency for  $\text{Zn}_x\text{Hg}_{1-x}\text{Se}$  and  $\text{Cd}_x\text{Hg}_{1-x}\text{Se}$  shows the similar tendency for HgSe. The compensation in our samples is about 30% for doubly ionized impurities (donors and acceptors). (Author abstract) 14 refs.

**096752 MAGNETIC SUSCEPTIBILITY OF A TWO-DIMENSIONAL ELECTRON GAS IN THE STRONG MAGNETIC FIELD LIMIT AND FOR NON-ZERO TEMPERATURES.** Analytic expressions are derived for the magnetic susceptibility and the Fermi energy of a non-interacting two-dimensional electron gas in the strong field limit and for non-zero temperatures. The results at zero temperature agree with existing calculations but the results at finite temperature are different from those obtained recently by other authors. The results are relevant to studies of MOSFET inversion layers and GaAs/AlGaAs heterojunctions. (Edited author abstract) 13 refs.

Wang, L. (Louisiana State Univ, Baton Rouge, LA, USA); O'Connell, R.F. *Phys Status Solidi B* v 144 n 2 Dec 1987 p 781-786.

**096753 BAND STRUCTURE ENGINEERING FOR MAXIMAL LIGHT-HOLE BEHAVIOUR IN STRAINED QUANTUM WELL SYSTEMS.** We show that the highest valence subband can be light-hole-like over a significant energy range (50-100 meV) in the plane of a strained layer superlattice where (i) the light hole and heavy hole confinement wells are in different regions of the superlattice and (ii) the heavy hole confinement well is deeper than the light hole confinement well. The separate confinement minimizes the interaction between light hole and heavy hole zone center states, thus reducing subband non-parabolicity due to state mixing, while the different well depths enhance the splitting between the highest heavy hole and light hole states. (InAlGa)As-(GaAl)As should be an ideal material system to demonstrate maximal light-hole behavior, behavior of significant benefit for high hole mobility and optoelectronic applications. (Author abstract) 17 refs.

**096754 NEW, MORE ACCURATE METHODS FOR THE INVESTIGATION OF THE FREE CARRIER CONCENTRATION AND MOBILITY BY 1/NOISE MEASUREMENTS.** The proposed new method can be applied to materials that obey the Hooge-Vandamme relation. The result for  $n$ , given by the method, is independent of the actual mobility  $\mu$ , and weakly depends on the noise factor  $\alpha_H$ . Almost the same procedure can be applied for the investigation of  $\mu$ . The problem of temperature dependence investigations is considered. (Edited author abstract) 10 refs.

Kiss, L.B. (JATE Univ Szeged, Hung); Torok, M.I.; Hevesi, I. *Solid State Commun* v 61 n 11 Mar 1987 p 731-732.

**096755 EFFECT OF ANISOTROPY AND WARPING ON THE AUGER LIFETIME OF DIRECT GAP SEMICONDUCTORS.** We show that the result  $\tau^{-1}$  approximately equals  $(k_B T/E_g)^{3/2} \exp(-\lambda E_g/k_B T)$  for the Auger rate of direct gap semiconductors is only valid for electrons and holes having a dispersion relation with spherical symmetry. Although the exponential term is still given by the threshold energy for the Auger process, the prefactor has to be multiplied by  $(k_B T/E_g)^{1-p/2}$  where  $p = 0, 1$  or  $2$  is essentially the dimensionality of the dispersion relation symmetry. If the valence band warping is taken into account, we have  $p = 0$ . (Edited author abstract) 8 refs.

**096756 DENSITY OF STATES OF A TWO DIMENSIONAL ELECTRON GAS IN A HIGH MAGNETIC FIELD STUDIED WITH PHOTOLUMINESCENCE.** The density of states of a quasi-two-dimensional electron gas in magnetic fields up to 25 T is determined directly from photoluminescence measurements and can be described by Gaussian broadened Landau levels superimposed on a constant background. A model for electron-acoustic phonon scattering is presented to explain the observed filling factor ( $\nu$ ) dependence of the width of the partially filled first Landau level  $\Gamma_1$ , while it is suggested that the  $\nu$  dependence of the width of the completely filled zeroth Landau level  $\Gamma_0$  can be attributed to long range impurity scattering. The background is found to be independent of  $\nu$  and is assumed to have the same origin as  $\Gamma_0$  because of the resemblance in their dependence on electron temperature. (Edited author abstract) 25 refs.

**096757 BIPOLARON EFFECTS ON THE LAT-**

**TICE ENERGY OF  $\text{Ti}_4\text{O}_7$ .** Taking into account the electron-phonon interactions proposed by P.W. Anderson, the lattice energy in semiconducting  $\text{Ti}_4\text{O}_7$ , below the metal-to-semiconductor transition temperature, in which bipolarons are formed, is calculated, using the polarizable point ion shell model developed by G.J. Dienes et al. The electron-phonon coupling constants ( $\lambda$ ) which represent the strengths of the electron-phonon interactions are estimated by fitting the ionic spacings calculated theoretically to the experimental ones. The coupling constant between the electron trapped at a  $\text{Ti}^{3+}$  site and the phonon of the nearest cation ( $\lambda_{+}$ ) and that due to the phonon of the nearest anion ( $\lambda_{-}$ ) are found to have values of  $-107.0 \text{ eV nm}^{-1}$  and  $14.0 \text{ eV nm}^{-1}$ , respectively. (Edited author abstract) 21 refs.

**096758 MONTE CARLO INVESTIGATION OF THE NEAREST-AVAILABLE-NEIGHBOR DISTRIBUTION IN THREE DIMENSIONS: A MODEL FOR ELECTRON-HOLE RECOMBINATION IN SEMICONDUCTORS.** A Monte Carlo calculation is presented of the range-dependent survival probability of an initially randomly distributed electron-hole population recombining according to a nearest-available-neighbor rule. It confirms a previous prediction of an asymptotic power-law behavior in three dimensions, with exponent  $-3/2$ . The distribution of surviving electrons and holes in the asymptotic region takes the form of two interlacing electron and hole networks. The relevance of the nearest-available-neighbor recombination model as an approximation to real systems is discussed. (Author abstract) 10 refs.

**096759 COHERENT AND SEQUENTIAL TUNNELING IN SERIES BARRIERS.** A simple approach which can describe both coherent tunneling and sequential tunneling is applied to resonant tunneling through a double-barrier structure. This approach models phase-randomizing events by connecting to the conductor a side branch leading away from the conductor to a reservoir. The reservoir does not draw or supply a net current, but permits inelastic events and phase randomization. A conductance formula is obtained which contains contributions due to both coherent and sequential tunneling. We discuss the limiting regimes of completely coherent tunneling and completely incoherent transmission, and discuss the continuous transition between the two. Over a wide range of inelastic scattering times tunneling is sequential. The effect of inelastic events on the peak-to-valley ratio and the density of states in the resonant well is investigated. We also present an analytic discussion of the maximum peak conductance  $e/k$  of an isolated resonance in a many-channel conductor. (Author abstract) 34 refs.

**096761 SIMPLE MODEL FOR THE ORIGIN OF CHAOS IN SEMICONDUCTORS.** It is shown how a simple model for chaos in semiconductors results from a

three-fold argument: (a) One starts with a Chapman-Kolmogorov equation for the generation-recombination processes. These are assumed in the simplest case (considered here) to be uniform in space and to involve only holes. A recurrence relation for the average hole concentration at successive discrete time intervals is derived by averaging the Chapman-Kolmogorov equation. (b) One sets up a generation-recombination rate for a specific model. (c) The possibility of chaos then follows by combining (a) and (b) and hence finding a recurrence relation of the type  $x_{k+1} = f(x_k)$  with quadratic maximum, which is known to produce a period doubling route to chaos. (Author abstract) 25 refs.

**096762 THERMODYNAMICS OF THE COULOMB LATTICE GAS WITHIN THE MEAN SPHERICAL APPROXIMATION.** The free energy of the classical two-component three-dimensional Coulomb lattice gas is derived in the explicit form within the mean spherical approximation. The model exhibits three important features: the onset of the condensation into the NaCl-like ordered phase, the critical point which is probably connected with condensation effects and the critical point of the 'gas-liquid' type at the low concentration. (Author abstract) 17 refs.

Mitas, L. (EPRC SAS, Bratislava, Czech). *Solid State Commun* v 65 n 11 Mar 1988 p 1401-1404.

**096763 MECHANISM FOR TWO-ELECTRON CAPTURE AT DEEP LEVEL DEFECTS IN SEMICONDUCTORS.** We have studied two-electron capture in nonradiative recombination when the energy of recombining charge carriers is transferred to the lattice via the deep level defect's local vibration mode. Unlike recombination due to electron-phonon interaction, the proposed model is based on the electron-electron integration in the conduction band with simultaneous excitation of the deep level defect's local vibration mode. We also consider the spin-dependent, field- and temperature-induced effects relevant to the present two-electron capture mechanism, and demonstrate the existence of the gigantic capture cross section provided that both deep level defects responsible for recombination are correlated in distribution with shallow donors and a multiphonon transition is most favored. In the context of the local negative-U concept, the two-electron capture mechanism can account for the observed dynamics of rapid recombination due to (i) deep level double-charged centers at the sites of Si lattice, (ii) antisite defects in III-V compounds, and (iii) 'interstitial atom + vacancy' type elastic defects stabilized by internal strain in silicon. (Author abstract) 13 refs.

**096764 PREDICTION OF LINE INTENSITIES AND INTERPRETATION OF ACCEPTOR SPECTRA IN SEMICONDUCTORS.** The optical absorption strength of acceptors in semiconductors is calculated in the effective-mass approximation. The spherical-model description of acceptor states explains the main features of the experimental IR spectra. The strength of intensity of the D and C lines ( $2P_{3/2}$  final states) relative to that of the G line ( $2P_{3/2}$  final state) results from the presence of a d-like component in the acceptor ground state. The line intensities in Si and Ge are calculated beyond the spherical model including valence-band warping, coupling to the split-off valence band and q-dependent screening. The results reproduce available experimental data and provide useful additional information for the interpretation of those data. (Edited author abstract) 11 refs.

**096765 CARRIER KINETICS IN A SEMICONDUCTOR WITH LIGHT-INDUCED GAPS.** Due to the influence of a strong electromagnetic field an induced gap

is expected to occur in the band structure of a semiconductor. In this paper the influence of the damping by electron-phonon collisions and by recombination on the new band structure is investigated. Taking into account damping kinetic equations for the electrons are derived and discussed with the help of calculations. (Author abstract) 11 refs.

**096766 GREEN'S FUNCTION APPROACH TO NONEQUILIBRIUM CHARGE CARRIERS IN DIRECT GAP SEMICONDUCTORS GENERATED BY SHORT LIGHT PULSES.** In the present paper the Green's function approach to nonequilibrium quasi-free charge carriers in highly excited semiconductors is applied. In doing this a system of kinetic equations for generalized Wigner distributions of renormalized quasi-electrons and holes is obtained, that takes into account (additionally to well-known published results) the interaction of the longitudinal optical phonons and the intraband interaction of the radiation field with the electron-hole plasma. Thus, utilizing the corresponding field equations and the suitable boundary conditions, relaxation processes in the semiconductor after excitation by a short laser pulse and a laser probe beam experiment may be described. **096767 DETECTION OF FIR RADIATION BY PHOTON DRAG OF FREE CARRIERS IN SEMI-METAL THIN FILM.** Fast ns. response with good sensitivity of far infrared radiation (FIR) is observed in anisotropic thin films of Bi and Sb evaporated at large angle. The signal in the wavelength region  $\gamma > 200 \mu\text{m}$  is assigned to the classical optical pressure on the free carriers while the signal in the 100 microns region can be assigned to a band transition. These detectors are currently used by us for time diagnostic of FIR laser Raman with a sensitivity 10-20 times larger than the best commercial Ge photon-drag detectors at wavelengths larger than 300 microns. **096768 NUMERICAL ANALYSIS OF THE EVOLUTION OF DYNAMIC GRATINGS IN SEMICONDUCTORS.** A method for numerically simulating the excitation and relaxation of photoinduced dynamic gratings of nonequilibrium charge carriers in semiconductors is described. Results calculated on the evolution of nonequilibrium carriers described by a system of equations consisting of the continuity equation and the Poisson equation, with nonlinear recombination, are reported. Writing pulses in the nanosecond range are considered. The effect of diffusion and recombination on the relaxation of the nonequilibrium carriers is determined for various grating periods. **096769 UEBER DIE LOESUNG VON EINDIMENSIONALEN MODELGLEICHUNGEN DES LADUNGSTRAEGERTRANSPORTES IN HALBLEITERN MIT EINER QUADRATURFORMELMETHODE.** [Solution of One-Dimensional Model Equations for Carrier Transport in Semiconductors with a Quadrature Formula Method]. The topic of the investigation is a class of linear integro-differential equations for the carrier transport in semi-conductors under the influence of constant electric fields. Quadrature methods for the solution of this equation - reformulated as an integral equation (Fredholm integral equation of the second kind with discontinuous kernel) - are considered. A complete solution algorithm which is based on a multiple interpolatory quadrature formula is given and demonstrated by numerical examples. (Author abstract) 11 refs. In German.

**096770 ELECTRON AND HOLE CYCLOTRON RESONANCE IN SEMIMETALLIC GaSb/InAs/GaSb QUANTUM WELLS.** Far-infrared magneto-transmission studies are reported on GaSb/InAs/GaSb quantum wells using circular polarized light. Electron and hole Landau level transitions are observed and identified by their selection rules. The effective masses and densities of both kinds of carriers are determined as a function of magnetic field and the InAs layer thickness. We find that the hole cyclotron resonance disappears at high magnetic fields due to depopulation of the holes when the ground hole Landau level crosses the Fermi level. (Author abstract) 9 refs.

**096773 EFFECT OF BROADENING OF TRAIL STATES ON THE EINSTEIN RELATION IN HEAVILY DOPED COMPENSATED SEMICONDUCTORS.** An attempt is made to study the dependence of the Einstein relation on carrier concentration in heavily doped compensated semiconductors with broadened tail states, both in the presence and absence of a quantizing magnetic field, taking n-InSb as an example. It is found that, corresponding to a given free electron concentration, the broadening of the tail states modifies the Einstein relation by enhancing the diffusivity-mobility ratio in the absence of magnetic quantization while the reverse is observed in the presence of a quantizing magnetic field. Besides, the ratio of decrease of the ratio with increasing magnetic field in the quantum limit is found to be independent of such broadening effects. (Author abstract) 14 Refs.

**096774 QUASIELASTIC LIGHT SCATTERING FROM FREE CARRIERS IN SEMICONDUCTORS WITH NON-PARABOLIC ENERGY BONDS.** Theory of quasielastic electron light scattering for non-parabolic semiconductors is developed. The scattering spectra are

shown to have Lorentzian profiles in doped semiconductors. The width of the Lorentzian is defined in terms of the thermal conductivity of the electron sub-system in case of light scattering from energy density fluctuations. The width of the Lorentzian in case of light scattering from spin density fluctuations is decided by electron diffusion. Frequency-dependent expressions for the coefficients of electronic diffusion, thermal diffusion and thermal conductivity coefficients are derived. (Author abstract). 11 refs.

**096775 TEMPERATURE AND CARRIER INJECTION-DEPENDENT CHARACTERISTICS OF BULK UNIPOLAR(BARRIER) SWITCHES.** The current/voltage characteristics of two-state homojunction barrier devices between 270K and 330K were investigated. Two new gated regenerative switching devices (the gated camel switch and the gated p plane barrier switch) are introduced. Carrier injection-dependent operational parameters, including switching voltage  $V_{SW}$ , switching current density  $J_{SW}$ , holding voltage  $V_H$  and holding current density  $J_H$  were studied. It is found that with increasing the injected electron or hole current density  $V_{SW}$  decreases while  $J_{SW}$  increases. The two holding point parameters  $V_H$  and  $J_H$  remain constant over the carrier injection range. A comparison between theoretical and available experimental results is included. (Edited author abstract). 6 refs.

**096776 THEORY OF CONDUCTANCE OSCILLATIONS OF NARROW 2D ELECTRON SYSTEMS IN HIGH MAGNETIC FIELDS.** The size and magnetic field quantization of electron motion in narrow 2D systems is investigated. The confining potential is approximated by an irregular set of parabolic quantum wells of various width connected in series. The conductivity is given the form which reflects the magnetic crossover in quantisation under high magnetic fields. It is shown that each 1D subband with the index  $n$ , which originates from size quantisation, is continuously transformed into a Landau level with the same index under the influence of magnetic field, i.e., the number of nodes of corresponding eigenfunctions is conserved. Thus, due to the magnetic field, all zero field conductance peaks pertaining to one subband index are grouped into one Landau level. The application of a magnetic field may serve as a useful tool for the determination of the number of 1D subbands in the system, which can otherwise be masked by universal conductance fluctuations. (Author abstract). 20 refs.

**096777 ANALYSIS OF TIME-OF-FLIGHT TRANSIT TIMES BASED ON THE MULTIPLE-TRAPPING MODEL OF CHARGE-CARRIER TRANSPORT.** Within the context of the multiple-trapping model, we discuss different theoretical ways of defining a transit time in the time-of-flight experiment. A new definition based on the first moment with respect to space of the free-carrier distribution is proposed. At the same time various experimentally used definitions of transit time are identified and the corresponding operational values are extracted from Monte Carlo simulated time-of-flight current traces for different field strengths and temperatures, with either an exponential or a linear density of tail states. The theoretical and Monte Carlo results for the different approaches are compared. Definitions of transit time that emphasize the fastest of the drifting carriers exhibit a larger electric field dependence and a smaller apparent activation energy than definitions based on the totality of excess charge carriers. Consequently, to analyse drift-mobility data in the multiple-trapping framework, one has to use a theoretical definition compatible with the procedure used in extracting the experimental transit times. (Edited author ab-

stract). 27 refs.

**096778 PERCOLATIVE TRANSPORT IN AMORPHOUS SEMICONDUCTORS.** For phonon-assisted transport between localized electronic states in amorphous semiconductors, the conductance of the medium is known to be the same as that of an equivalent resistor network. If the impedances of the resistors between adjacent sites vary over several orders of magnitude, this conductance is determined mainly by the magnitude of the critical impedance  $Z_c$  such that a percolation path through the system of resistors with impedance less than  $Z_c$  exists only if  $Z_0 \geq Z_c$ . Various methods for calculating  $Z_c$  and its dependence on the parameters of the system, are compared for a model system in which all the states have one of two discrete energies. Our main conclusion is that in the calculation of  $Z_c$  from the mean number of bonds per site, it can be very important to optimize the range of sites and bonds that are considered. **096779 LASER BEAM INDUCED CURRENT MEASUREMENTS OF MINORITY CARRIER DIFFUSION LENGTH.** Techniques for extracting values of bulk diffusion length from experimental LBIC (laser-beam-induced current) curves are presented for both parallel and perpendicular barrier-beam geometries and for both thick and thin samples. Experimental tests of each technique compare diffusion length results obtained for samples of different geometries with each other, with confirmation of results by measuring the minority carrier lifetime by photoconductivity decay in samples cut from the same wafers and then calculating the diffusion length. The LBIC techniques presented are shown to allow practical and meaningful determination of diffusion length, and to have significant advantages over the techniques from which they evolved. **096780 EXCITON LINEWIDTH DUE TO SCATTERING FROM FREE CARRIERS IN SEMICONDUCTING QUANTUM WELL STRUCTURES.** The contribution to the exciton linewidth in semiconducting quantum well structures due to the scattering of excitons by free carriers is calculated. It is found that this contribution becomes very important in limiting the exciton linewidth when a high density of free carriers is present or at low temperatures where the scattering of the excitons by optical and acoustic phonons is reduced. This contribution to the linewidth in quantum well structures is found to increase with the free carrier concentration and to extremely broaden the exciton peak at high carrier concentrations. At lower carrier concentrations, where the carrier behave as a nondegenerate gas of particles, the contribution to the exciton linewidth due to scattering by free carriers increases with temperature. (Author abstract) 13 refs.

**096781 EFFECT OF CONTINUUM RESONANCES ON HOT CARRIER TRANSPORT IN QUANTUM WELLS.** In addition to bound states, quantum wells also produce resonant states in the continuum. While bound states have received considerable attention and are now the basis of device applications, the corresponding virtual states have hardly been studied. We investigate the

influence of these resonant states on hot electron transport in quantum wells. We find that the matrix elements which determine scattering rates exhibit structure at the resonant energies. This leads to suppression of scattering by polar optical phonons relative to nonpolar optical and acoustic phonon scattering. We discuss the effect that these states have on the capture and release of carriers by the quantum well. (Edited author abstract) 10 refs.

**096782 INTERSUBBAND RELAXATION OF PHOTOEXCITED HOT CARRIERS IN QUANTUM WELLS.** We have probed the dynamics of hot electrons in undoped GaAs/(GaAl)As quantum wells using time-resolved Raman techniques. By tuning the photon energy of a time-delayed weak probe, we study the  $n=1$  to  $n=2$  or  $n=2$  to  $n=3$  intersubband transitions by electronic Raman scattering. The lifetime and the intersubband scattering time of the electrons photoexcited on the lowest electronic subbands are determined separately. Calculation of the rate of intersubband scattering by longitudinal acoustical phonons accounts for the observation of relatively long lived electrons on the second subband of a 215 Angstrom MQWS. When the well is narrower, so that the  $n=2$  to  $n=1$  transition can occur with emission of a longitudinal optical phonon, we find that the lifetime of carriers in the  $n=2$  band is too short to measure with our technique. (Edited author abstract) 19 refs.

**096783 SECONDARY EMISSION STUDIES OF HOT CARRIER RELAXATION IN POLAR SEMICONDUCTORS.** The details of the initial relaxation of optically injected hot carriers in polar semiconductors are studied by Raman scattering from nonequilibrium LO phonons and anti-Stokes hot luminescence. Experiments on intrinsic and doped GaAs reveal carrier-phonon and carrier-carrier interaction times, the wavevector dependence of the hot phonon distribution, and the influence of holes on the LO phonon lifetime. Studies in  $Al_xGa_{1-x}As$  probe the influence of alloy disorder on the generation of hot phonons. Because there are two optic phonon modes in  $Al_xGa_{1-x}As$ , we can experimentally measure the effect of ionicity (the frequency difference between LO and TO phonons) on the generation rate for the hot phonons. **096788 NONLINEAR ENERGY RELAXATION OSCILLATIONS AND CHAOTIC DYNAMICS OF HOT CARRIERS.** It is shown that recently observed complex chaotic behavior associated with low temperature impurity breakdown can be understood by introducing the mean energy per carrier  $E$  as an additional dynamic variable besides the carrier densities. A set of coupled nonlinear evolution equations for the carrier density and mean energy is derived by a moment expansion of the Boltzmann equation including impact ionization. This process leads to a novel, strongly nonlinear relaxation term in the dynamic energy balance equation. The simplest, spatially homogeneous version of the model yields hysteretic or non-hysteretic static current-voltage characteristics, and spontaneous self-sustained current oscillations. It can also be used to explain the coupling of the oscillations in two spatially separated hot carrier subsystems via energy exchange. (Edited author abstract) 14 refs.

**096790 ELECTRON-HOLE DRAG IN SEMICON-**

**DUCTORS.** Transport of minority carriers in semiconductor plasmas can be strongly affected by electron-hole scattering. In high-mobility carrier systems not only the presence of one carrier type, but also its drift velocity determines the transport of the other carrier type via electron-hole scattering. This effect is known as 'carrier drag'. In modulation-doped quantum well structures the carrier drag is strong enough to cause 'negative absolute mobility' of both minority electrons and holes. We describe all-optical transport measurements, from which momentum relaxation times by electron-hole scattering are quantitatively determined. Extremely short scattering times result for minority electrons in a hole plasma (40 to 100 fs) in contrast to the reverse case of holes in an electron plasma (2-5 ps). The physical reasons (mass ratio, degeneracy, two-dimensionality) are discussed, as well as new phenomena as negative photoconductivity and plasma instabilities in the presence of strong electron-hole drag. (Edited author abstract) 30 refs.

**096791 SCATTERING PROCESSES IN SEMICONDUCTORS.** We give the variation with temperature and carriers density of the electron-phonon (e-ph) and electron-hole (e-h) collision times from the nondegenerate to the degenerate limits. We show that the e-h collision time is minimum not at very large density but when the plasma becomes degenerate. We also show that the collision time with acoustical phonons has a minimum in the degenerate domain. The corresponding density can be reached experimentally only for low temperature. We give an expression for the screening of the e-ph interaction, which was up to now taken incorrectly similar to the one for Coulomb interaction. (Edited author abstract) 5 refs.

**096796 OXIDATION OF Si-RICH CHEMICAL-VAPOR-DEPOSITED FILMS OF TUNGSTEN SILICIDE.** We have studied dry oxidation characteristics of Si-rich  $WSi_x$  thin films prepared by LPCVD directly on  $SiO_2$  with  $x=2.7$  for as-deposited films. It has been reported previously that thin (less than 100 nm) CVD tungsten silicide adheres well to  $SiO_2$ . Using Auger depth profiling and Rutherford backscattering spectroscopies, we find that silicon in excess of stoichiometric  $WSi_2$  diffuses through the silicide toward the surface to form a  $SiO_2$  passivating overlayer. The extracted activation energy for this oxidation process is  $E_a=1.2$  eV, consistent with oxygen diffusion in  $SiO_2$ . A similar value of  $E_a$  is found for  $WSi_x$  deposited on polysilicon. During the anneal, the stoichiometry  $x$  of  $WSi_x$  decreases monotonically with the annealing temperature, reaching  $x=2$  after 30 min at 900°C or 20 min at 950°C. Longer times or higher temperatures result in silicon depletion, with  $x=1.7$  after 30 min at 1000°C. (Edited author abstract) 13 refs.

**096799 ACOUSTOELECTRONIC INTERACTION IN A SEMICONDUCTOR WITH PERIODICALLY ARRANGED CONTACTS IN A VARYING ELECTRIC FIELD.** Acoustoelectronic effects in semiconductors and layered piezoelectric-semiconductor structures with a periodic system of ohmic contacts, which produces an electric field in the semiconductor that varies in space and time, are investigated. Interest in a systematic investigation of acoustoelectronic effects in such structures has been stimulated by the discovery of a whole series of effects in them: frequency conversion and multiplication and synchronous signal detection. The use of periodic arrays of ohmic contacts opens up the possibility for the direct observation of electron waves, excited through the simultaneous stimulus of the piezoelectric field of the acoustic wave and the varying drift field. Formulas are given and analyzed in this paper that describe electron absorption and the velocity of acoustic waves in a varying field when its phase is taken into consideration; expressions are also given for the acoustoelectric current, detected by the periodic array of contacts. (Author abstract) 10 refs.

## Cooling

**096801 HOT CARRIER COOLING IN GaAs QUANTUM WELLS.** The cooling of a hot electron-hole plasma in undoped, p-doped, and n-doped GaAs/Al-GaAs quantum wells of three different thicknesses (3, 9, and 20 nm) is investigated by picosecond luminescence spectroscopy. The energy loss of holes due to the Froehlich interaction is at low excitation densities independent of well width and close to the value obtained by a simple theory. The rate strongly decreases with increasing excitation density. For electrons, the energy loss is even at low densities strongly reduced compared to the simple theory of the Froehlich interaction. The reduction of the energy loss at high densities is independent of dimensionality and well width and not caused by screening or degeneracy effects. The energy loss due to acoustic deformation potential scattering depends on well width. (Author abstract) 25 refs.

## Crack Propagation

**096802 CONDITION OF CRACK PROPAGATION IN A BRITTLE FILM WITH CONSIDERATION OF ITS PENETRATION INTO THE SUPPORT MATERIAL.** Conditions of crack propagation in a brittle film applied to the support when tensile stresses exist in the latter are considered. It is shown that under definite conditions the crack penetrates to the support. An

expression is obtained for critical thickness of the film beginning from which the appeared crack propagates along the support. It is shown that critical thickness of the film depends on the fracture toughness of both the support material and the film. (Edited author abstract) 11 refs. In Russian.

**096803 ELECTRON-PHONON INTERACTION IN SEMICONDUCTOR SUPERLATTICES.** The single-particle Hamiltonian of the electron-long-wave optical phonon interaction is discussed for semiconductor superlattices—the dispersion relations of long-wave optical phonons, i.e., the interface-like bulk phonons (IBPs) and longitudinal optical (LO) phonons of the polar semiconductor superlattice, are analyzed in detail. The IBPs are composed from ordinary interface phonons on adjacent interfaces coupling through their macroscopic electric fields to form a collective excitation of the superlattice. The coupling functions describing the modified Froehlich interaction of a single electron with the continuous field of polarization of the IBPs and LO phonons are discussed and presented in graphical form. (Edited author abstract) 27 refs.

**096804 LATTICE DYNAMICS FOR SUPERLATTICES.** The acoustic and optic modes of a one-dimensional model of a diatomic superlattice are considered. By employing a microscopic theory it is possible to explore the zone-folding characteristics. The treatment is based on linear lattice dynamics with nearest neighbour interactions. The equations of motion for the different atoms (on either side) at two superlattice interfaces replace the boundary conditions used in continuum theories. This microscopic approach has the advantage that both optic and acoustic branches are described within a single formulation and without recourse to the long wavelength limit. The algebra, which is otherwise quite involved, is simplified by the use of transfer matrix techniques. The spectrum contains a number of interesting features whose underlying physical principles are discussed. (Author abstract) 17 Refs.

**096805 ELECTRON-PHONON SCATTERING IN SEMICONDUCTOR SUPERLATTICES IN A QUANTIZING MAGNETIC FIELD.** Total electron-phonon scattering rates are obtained in an ideal superlattice in a quantizing magnetic field. The dispersion of an electron along the superlattice axis is assumed to be of a tight-binding type. Compact analytical expressions are possible for acoustic and nonpolar optical phonon scattering. The numerical results for acoustic and nonpolar optical phonon scattering rates are presented for the GaAs/Ga<sub>1-x</sub>Al<sub>x</sub>As superlattice and the effect of miniband width parameters on these scattering rates is discussed. (Author abstract) 11 Refs.

## Crystallization

**096808 THEORY OF ELECTRICAL TRANSPORT AND RECOMBINATION IN POLYCRYSTALLINE SEMICONDUCTORS UNDER OPTICAL ILLUMINATION.** A method for describing electrical transport in polycrystalline material has been developed by solving a current continuity equation that involves drift, diffusion and nonuniform generation rate of electron-hole pairs. By taking the recombination current at the grain boundary interface, at the grain boundary space-charge region, and at the bulk into consideration a theoretical method for grain boundary recombination has been developed. The author includes the effects of Shockley-Read-Hall recombination statistics, of trap-assisted recombination statistics, and of the heavy dopings of the semiconductor region(s). On the basis of the present theory the dependence of the grain-boundary potential-barrier height  $V$  on the grain size, doping concentrations, and carrier generation rate has been studied. It is found that the effective recombination velocity at the edge of the grain boundary space-charge region is a function of  $V$ , and that it increases with grain size until it attains a peak value. (Edited author abstract) 34 refs.

**096809 THEORY OF ELECTRON BEAM INDUCED CURRENT AND CATHODOLUMINESCENCE CONTRASTS FROM STRUCTURAL DEFECTS OF SEMICONDUCTOR CRYSTALS; STEADY-STATE AND TIME-RESOLVED PROBLEMS.** Electron-beam-induced current and cathodoluminescence are powerful tools for revealing and characterizing point-like defects, dislocations, and grain boundaries in semiconductor crystals. This paper reviews the theoretical studies of electron-beam-induced current and cathodoluminescence contrasts from local structure defects of semiconductor crystals (the geometrical aspects of both contrasts, the assessment of the defect properties from the contrast, the evaluation of bulk parameters in the presence of defects, and time-resolved characterization of defects), including recent developments in this area. (Author abstract) 80 refs.

**096810 LATTICE DISTORTION ASSOCIATED WITH ISOLATED DEFECTS IN SEMICONDUCTORS.** A semi-empirical tight-binding method is used to investigate the lattice relaxation around isovalent impurities and its effect on the vibrational properties of semiconductors. In terms of the revised Hartree-Fock atomic-term values, this technique provides simple analytical expressions for the change in the impurity-host bond energy and suggests a computationally efficient and reasonable method to estimate the bond-length distortions. Numerical calculations for the symmetric lattice relaxations are reported for eighty cases of impurity-host systems in nineteen elemental and compound semiconductors. The frequencies of the impurity modes in the dilute limit of mixed II-VI and III-V compounds are derived and the results are compared and discussed with the existing optical experiments and full lattice dynamical (Green's function) calculations. (Edited author abstract) 43 refs.

**096811 EFFECT OF DISORDERED REGIONS ON SEMICONDUCTOR JOULE HEATING.** The effect of radiation-induced disordered regions (DR) on the Joule heating of semiconductor is theoretically investigated. It is shown that both overheating and cooling of semiconductor near DR are possible depending on relation between DR and bulk thermal and electrical properties. Hence the existence of regions with different thermal and electrical properties in semiconductor material may both increase and decrease the probability of thermal breakdown. (Author abstract) 4 refs.

**096812 ATOMIC RADII IN TERNARY ADAMANTINES.** Bonded radii are derived for eight electropositive and four electronegative elements from line plots of total valence electron densities for 10 ternary chalcopyrites, in order to aid in understanding the defect chemistry of such compounds. They scale well with tetrahedral sulfide crystal radii, when a spherical atom approximation is made, in which case they are significantly closer to these than to covalent tetrahedral radii, as illustrated for several ternary chalcogenides. Their derivation confirms that the electronegative elements in these tetrahedrally bonded ternaries are better described by tetrahedrally distorted spheres. Still, models using these radii are to be preferred over the usual ball-and-stick types. (Edited author abstract) 28 refs.

**096815 POSITRON STUDY OF VACANCY DEFECTS IN PROTON AND NEUTRON IRRADIATED**

**GaP, InP, AND Si.** The annealing and fluence dependent concentration of defects produced by irradiation with fast neutrons and protons was studied by means of the positron annihilation technique (measurements of the positron lifetime and Doppler broadening lineshape of annihilation photons) and internal friction measurements. In proton bombarded GaP a two-stage annealing process is observed (stage I near 200°C and stage II near 600°C) and attributed to the annealing of point-like and extended defects, respectively. In neutron irradiated GaP all positron sensitive radiation defects disappear after annealing at 700°C. In all materials the positron lifetime and S-parameter increase with rising proton and neutron fluence. Elemental semiconductors exhibit stronger increases than compound semiconductors. (Author abstract) 32 refs.

**096818 DISTRIBUTION OF DEEP LEVEL PARAMETERS IN SPECTRAL ANALYSIS OF DLTS (SADLTS).** It is shown that one can estimate the broadening parameters of both the capture cross section  $\sigma$  and the activation energy  $E$  of a deep level from the emission rate spectrum  $S(\lambda, T)$  of the transient capacitance  $\Delta C(t, T)$  obtained in a spectral analysis of the DLTS (SADLTS) proposed in our previous paper. Numerical examples are given to illustrate typical cases of interest for an idealized model of independent Gaussian distributions,  $f(\sigma)$  and  $g(E)$ . In general,  $S(\lambda, T)$  is a convolution of  $f$  and  $g$  with its higher and lower  $\lambda$  side characterized by broadening parameters for  $\sigma$  and  $E$ , respectively. A simple formula is derived in order to obtain the central value  $E$  of the activation energy. (Author abstract) 25 refs.

**096822 INTERATOMIC POTENTIALS IN SEMICONDUCTORS AND THEIR VALIDITY FOR DEFECT CALCULATIONS.** We discuss the validation of interatomic forces for defect calculations in semiconductors like silicon. Our tests include estimates of lattice response functions, defect steric energies, and relaxed atomic positions near defects. We find the variation from one potential to another to be substantial, notably because of the dominance of the bond-angle terms in the energy. Differences are less serious in the predicted geometries than in the predicted energies, which indicates preferred strategies for finding relaxed geometries. (Author abstract). 56 Refs.

**096825 PROCEEDINGS OF THE FIFTH INTERNATIONAL CONFERENCE ON THE PROPERTIES AND STRUCTURES OF DISLOCATIONS IN SEMICONDUCTORS.** The proceedings contains 32 papers. Some of the specific topics discussed are: photo-ESR studies on silicon containing dislocations; deep levels due to dislocations in CdS; effects of plastic strain on the theoretical parameters of GaAs; an induced-current study of defects in strained silicon; and grain-boundary conductivity in germanium. All papers are separately indexed and abstracted. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10743 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

Anon. *Bull Acad Sci USSR Phys Ser* v 51 n 4 1987, Proc of the Fifth Int Conf on the Prop and Struct of Dislocat in Semicond, Moscow, USSR, Mar 17-22 1986 179p.

**096826 TOPOLOGICAL DISORDER AND ELECTRON STATES IN PLASTICALLY STRAINED ONE-COMPONENT SEMICONDUCTORS.** Semiconductors represent extremely convenient materials for researching the electronic parameters of topologically disordered crystals, since the strong-bond approximation operates well for them. An example of such a crystal is taken here as a one-component semiconductor containing a dislocation time. Here we discuss characteristic features of the electron states in crystals containing dislocations by means of a simple model that, however, retains the main features identified previously in more realistic but more complicated ones. 9 refs.

Kawamura, K. *Bull Acad Sci USSR Phys Ser* v 51 n 4 1987, Proc of the Fifth Int Conf on the Prop and Struct of Dislocat in Semicond, Moscow, USSR, Mar 17-22 1986 p 24-27.

**096827 THEORETICAL STUDY OF CHARGE TRANSFER AND BOUND ELECTRON STATES AT DISLOCATIONS IN SEMICONDUCTING COMPOUNDS.** A study is made of the consequences of charge transfer occurring at dislocation cores containing unpaired bonds in compounds of elements of groups II-VI and III-V. Preliminary calculations have been performed on electronic levels in dislocations in GaAs and CdTe by other authors. 17 refs.

Teichler, H.; Grollich, M. *Bull Acad Sci USSR Phys Ser* v 51 n 4 1987, Proc of the Fifth Int Conf on the Prop and Struct of Dislocat in Semicond, Moscow, USSR, Mar 17-22 1986 p 28-33.

**096828 EFFECTS OF POINT DEFECTS ON DISLOCATION MOBILITY IN PEIERLS POTENTIAL RELIEF.** Measurements on dislocation mobility over a wide enough temperature range can in principle detect changes in the activation energy for the dislocation speed corresponding to the transition from kink generation at point defects (low temperatures) to free generation at higher ones. Such a transition has been observed in measurements on the mobilities of individual dislocations in silicon, namely from 2.3 C ev at  $T < 1050^\circ\text{C}$  to 4 ev at  $T > 1050^\circ\text{C}$ . 12 refs.

**096829 MICROHARDNESS ANISOTROPY AND POLARITY IN ELEMENTAL SEMICONDUCTING AND IN  $A^{III}B^V$  SEMICONDUCTOR COMPOUNDS.** Microhardness measurements have been made on faces of Ge, GaAs, and InSb single crystals at 20-400°C by means of Vickers and Knoop indentors. It is concluded that the experiments on microhardness anisotropy and polarity

can be used to provide semiquantitative information on dislocation speeds in semiconductors, particularly the relative speeds of A(g) and B(g) dislocations in  $A^{III}B^V$  compounds. Experiments on microhardness anisotropy are more sensitive at low temperatures possibly because of the slower fall in the stresses with distance produced by a Knoop indenter. 13 refs.

**096832 PROCEEDINGS OF THE FIFTH INTERNATIONAL CONFERENCE ON THE STRUCTURE AND PROPERTIES OF DISLOCATIONS IN SEMICONDUCTORS.** This conference proceedings contains 35 papers. Among the subjects covered are the following: configuration defects in plastically strained CdS crystals, interaction of dislocations and indium in GaAs, strain-induced defects in silicon, scanning DLTS study of GaAs defect distributions and energy levels, effects of space-charge cylinders on dislocation EBIC profiles, EBIC and cathodoluminescence contrast due to individual dislocations, silicon EBIC measurements, EBIC dislocation contrast, high-resolution electron microscopy, dislocation recombination X-ray topography and laser interferometers with WFR mirrors. All of the papers are abstracted and indexed separately. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11230 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

Anon. *Bull Acad Sci USSR Phys Ser* v 51 n 9 1987, Proc of the Fifth Int Conf on the Struct and Prop of Dislocat in Semicond, Moscow, USSR, Mar 17-22 1986 175p.

**096833 ANISOTROPIC DEFECTS IN  $A^{III}B^V$  SEMICONDUCTING COMPOUNDS.** Various types of defect influence the operation of optoelectronic devices. Dislocations act as sources of dark-line defects (DLD) and are important in optical-element degradation. Also, microdefects act as radiationless recombination centers. A new type of line defect has been identified in  $A^{III}B^V$  semiconductor compounds, which is of vacancy type and is oriented in  $[11\bar{0}]$  directions. (Edited author abstract) 3 refs.

**096834 DIFFRACTION ELECTRON MICROSCOPY IN SEMICONDUCTOR DEFECT RESEARCH.** Effects of two types were examined: a) image displacement, and b) amplitude changes in the intensity oscillations (including additional oscillations lacking from focused pictures). The displacement directions were determined by the signs of the defect-plane inclinations, and they are most clearly seen in dark-field pictures produced with large excitation errors. The intensity variations and the new oscillations are most prominent on pictures corresponding to small errors. The signs of the defects can be determined by examining the displacements and intensity variations on defocusing. 27 refs.

Maksimov, S.K. *Bull Acad Sci USSR Phys Ser* v 51 n 9 1987, Proc of the Fifth Int Conf on the Struct and Prop of Dislocat in Semicond, Moscow, USSR, Mar 17-22 1986 p 49-53.

**096835 EFFECTS OF SPACE-CHARGE CYLINDERS ON DISLOCATION EBIC PROFILES.** The calculation method has been proposed for deriving the dependence of the EBIC contrast on the radius of the space-charge cylinder for various values of parameters such as dislocation depth and diffusion length. Profiles have been examined for the current density passing through parts of a dislocation. The results of this study and others show that the space-charge cylinder radius is determined by the screening atmosphere of the space charges compensating the charge on the dislocation. There are some discrepancies between the measured contrast and the values found in the calculations. 13 refs.

**096837 IRBIC SEMICONDUCTOR DEFECT PICTURES.** A new method is described for imaging defects, particularly dislocations, in scanning electron microscopy by recording the infrared-beam induced current. The apparatus built in the authors' laboratory has very high sensitivity and enables one to perform the following: a) to measure infrared beam induced currents (IRBIC) and to obtain infrared images (IRBIC is analogous to the electron-beam induced current EBIC method), b) to perform traditional photoconductivity-spectrum measurements, and c) to check the filling of levels in the forbidden band on monochromatic illumination during local photoconductivity measurement. The IRBIC data have been examined to confirm the type of radiation defect produced in the scanning electron microscope (SEM). The results for the photocurrents and infrared contrast due to dislocation lines are at least in partial agreement with the DLTS data from various sources. (Edited author abstract) 11 refs.

## Deformation

**096839 EFFECTS OF PLASTIC DEFORMATION ON THE ELECTRICAL CONDUCTIVITY OF S<sub>m</sub>S SINGLE CRYSTALS.** Single crystals of semiconducting S<sub>m</sub>S, grown by a Bridgman method, have been compressed at room temperature by a few percent, and the effects of deformation on the electrical conductivity have been investigated between room and liquid-helium temperatures. For deformed crystals, the conductivity measured below 20 K in a direction parallel to the edge dislocations is orders of magnitude larger than that of the undeformed crystals. This increase is interpreted in terms of the existence of a metallic region along the core of the edge dislocation. The activation energy of the conductivity at around liquid-nitrogen temperature exhibits an anisotropy after deformation, which is explained by segregation of donor S<sub>m</sub> interstitials in the strain field of edge dislocations. (Author abstract) 15 refs.

## Degradation See Also SEMICONDUCTING SILICON—Amorphous.

**096840 DISLOCATIONS OR POINT DEFECTS: A STUDY OF DEEP LEVELS IN MECHANICALLY STRESSED GaP p-n JUNCTIONS.** Degradation is a very important effect for devices made from Al<sub>III</sub>B<sub>V</sub> compounds; major parts are played by dislocations and stress inhomogeneities, but the mechanism is not entirely clear. The authors have examined the behavior of deep levels associated with degradation in order to elucidate it. Further research has shown that a family of such deep levels can arise without substantial degradation, but in that case the spectra obtained by deep-level transient spectroscopy DLTS are very much dependent on the illumination, minority injection, and heat treatment. These levels have been detected here in a light-emitting diode. 7 refs.

## Diffusion

**096844 SINGULARITIES IN DETERMINATION OF THE DIFFUSION COEFFICIENTS OF COMPONENTS IN MELTS OF A<sup>III</sup>B<sup>V</sup> SYSTEMS.** A critical analysis is performed of the mathematical expressions used to compute the diffusion coefficients of components on the basis of data on the growth rate or dissolution of crystals of A<sup>III</sup>B<sup>V</sup> compounds. It is shown that neglect of high-order terms of the series that are the solution of the mass transport differential equations will result in substantial errors during processing of the experimental results. To simplify the computations and eliminate mathematical inaccuracy, it is proposed to use the analytic solution of the diffusion mass transport equations in the approximation of a semi-infinite medium. The diffusion coefficients of arsenic in liquid indium in the 550-750° C temperature range is computed on the basis of experimental results on the rate of InAs dissolution in an unsaturated In-As melt by using the method proposed. (Author abstract) 12 refs.

**096845 ONE-DIMENSIONAL MODELLING OF DIFFUSION IN SEMICONDUCTORS DURING CRYSTAL GROWTH.** A simple approach is developed for modeling the distribution of dopant in crystals grown by the Czochralski technique. Allowance is made for the temperature dependence of the diffusivity and for the diffusion of dopant behind the moving boundary. It is found that the effect can make a significant difference to the final dopant distribution. The diffusion process is modeled using a discrete method, previously developed for situations in which the boundary is static. (Author abstract) 9 refs.

**096846 FINITE-ELEMENT ANALYSIS OF CONVECTIVE DIFFUSION EQUATION FOR SEMICONDUCTOR PROBLEMS USING CONJUGATE GRADIENT METHOD.** By means of a finite-element method, the nonsteady-state convective diffusion equation describing the diffusion problem in a semiconductor is discretized. A conjugate gradient method is applied to the resultant matrix for analysis of the problem. A technique is applied to the equation before discretization so that a windward discretization is applied. As a result, suppression of the parasitic spatial oscillation and improvement of convergence have been attained. Both these points are problems in conventional finite-element methods. However, by means of the improvement herein, both the accuracy and the computation time have been improved. The result has been applied to the semiconductor diffusion equation and the convective diffusion equation, and the effectiveness of the method has been confirmed. (Author abstract) 7 refs.

**096848 DIFFUSION MECHANISMS IN II-VI MATERIALS.** Diffusion processes play a crucial role in the growth and subsequent processing stages of semiconductors, not least in the II-VI semiconductor materials. The present situation with respect to self-, impurity and inter-diffusion is considered. Chalcogen self-diffusion shows a consistent pattern for all of the II-VI materials and involves a single diffusion mechanism over most of the composition range. Metal self-diffusion however reveals a more complex situation with simultaneous contributions from several different defects. The metal self-diffusivity can be enhanced by impurity doping. Impurity diffusivities exhibit a variety of features whose interpretation at present is limited to the simplest cases. Empirical correlations are found between the pre-exponential factors ( $D_0$ ) and the activation enthalpies ( $Q$ ) for diffusion which have value in the interpolation or extrapolation of data. (Author abstract) 119 refs.

**096849 SOLUBILITY OF ZINC IN INDIUM ANTIMONIDE OVER VARIOUS SECTIONS OF THE TERNARY SYSTEM In-Sb-Zn.** It is established that the solubility of zinc in indium antimonide over various sections of the ternary system In-Sb-Zn is of retrograde character. This retrogradation is most clearly expressed over the In-Sb-Zn section, on which the maximum solubility of zinc in indium antimonide is 1.51 at.% at 480°C. On all the sections studied the maximum solubility of zinc is observed at one and the same temperature of 480°C and amounts to 1.30 at.% for the InSb-ZnSb section, 1.29 at.% for the InSb-Zn<sub>3</sub>Sb<sub>2</sub> section and 0.76 at.% for the InSb - (0.51 In+0.5 Zn) section. The zinc content in a solid solution of Zn in InSb at the eutectic melting point of 280°C coincides with literature data. In Russian. 5 refs.

**096855 ELECTRONIC STRUCTURE OF PURE AND DOPED ORTHORHOMBIC  $\text{La}_2\text{CuO}_4$ .** The electronic structure of orthorhombic  $\text{La}_2\text{CuO}_4$  has been investigated by first principles pseudofunction band calculations and group theoretical analysis. We find that pure as well as doped compounds remain metallic at all finite temperatures as a consequence of the  $\text{Cmca}$  ( $D_{2h}^{18}$ ) space group symmetry. The experimentally observed rapid rise in resistivity below 30 K suggests a structural transition to a lower symmetry space group that could be driven

electronically or magnetically. One possible candidate is monoclinic  $\text{C2/m}$  ( $C_{2h}^3$ ) which is a subgroup of  $\text{Cmca}$  and can be obtained by distorting the Cu-O bonds or rotating the  $\text{CuO}_6$  octahedra. Implications for superconductivity are discussed. (Author abstract) 16 refs.

**096857 ELECTRON-MOBILITY ENHANCEMENT AND ELECTRON-CONCENTRATION ENHANCEMENT IN  $\delta$ -DOPED n-GaAs AT  $T=300$  K.** The electron-mobility of  $\delta$ -doped GaAs grown by molecular-beam epitaxy is determined for two-dimensional doping concentrations ranging from  $10^{10} \text{ cm}^{-2}$  to  $10^{13} \text{ cm}^{-2}$ . A mobility-enhancement (of up to a factor of four) of  $\delta$ -doped epitaxial layers over their corresponding homogeneously doped layer is found in highly doped layers at  $T=300$  K. Temperature-dependent Hall-measurements are performed to clarify the physical origin of the mobility-enhancement. The electron-mobility is roughly constant in the range  $4\text{K} \leq T \leq 300$  K. The Hall-mobility measurements confirm that (i) high degeneracy of the two-dimensional electron-gas, (ii) spatial electron-donor separation in  $n=1,3,\dots$  subbands, as well as (iii) screening are the origins of high room-temperature mobility of  $\delta$ -doped GaAs. Extremely high free-electron-concentrations of  $n_{2\text{DEG}}=2 \times 10^{13} \text{ cm}^{-2}$  can be obtained in  $\delta$ -doped GaAs, corresponding to three-dimensional concentrations  $9 \times 10^{19} \text{ cm}^{-3}$ . This electron-concentration enhancement is assumed to be due to a reduced Si-autocompensation. (Author abstract) 14 refs.

**096858 PHOTOREFLECTANCE SPECTROSCOPY OF GaAs DOPING SUPERLATTICES.** Room temperature photoreflectance of molecular beam epitaxy GaAs doping superlattices was measured. Additional structures corresponding to forbidden transitions ( $\Delta n \neq 0$ ) were observed at very low pump beam intensity. Experimental results show that the dominant modulation mechanism of photoreflectance of doping superlattices is different from that of bulk materials. We suggest that the photoreflectance spectrum of doping superlattices have mainly first derivative functional lineshapes, which is caused by the subband shift in doping superlattices. The experiments are well explained by this mechanism. (Author abstract) 12 refs.

Tang, Yinsheng (Univ of Science & Technology of China, Hefei, China); Wang, Bingshen; Jiang, Desheng; Zhuang, Weihua; Liang, Jiben. *Solid State Commun* v 63 n 9 Sep 1987 p 793-796.

**096859 INFLUENCE OF PHOTO-MODULATION ON REFLECTANCE OF HETERO NIPI SUPERLATTICES.** The effect of room temperature photo-modulation on the reflectance of GaAs/AlGaAs hetero NIPI superlattices is reported. We propose a modulation mechanism which produces first derivative functional lineshapes in weak modulation limit. This model gives a good explanation of all the experimental phenomena. (Author abstract) 14 refs.

**096860 HYPERFINE INTERACTION IN PHOSPHORUS-DOPED AMORPHOUS SILICON-GERMANIUM ALLOYS.** We present a study of the hyperfine

structure in the electron spin resonance spectra of phosphorus-doped  $\text{a-Si}_{0.7}\text{Ge}_{0.3}\text{H}$ . Electron bombardment and annealing are used to vary the defect density and to shift the Fermi level in the range  $0.45 < E_C - E_F < 0.75$  eV. The main observation is that electron bombardment causes an enhancement of the density of hyperfine centers and a major decrease of the hyperfine splitting from 265 to 200 G. The data show that phosphorus introduces two hyperfine centers: the well known fourfold coordinated phosphorus atoms and a deep state the density of which can be enhanced by electron bombardment and hydrogen effusion. We suggest that the latter is a dangling-bond state on a twofold coordinated phosphorus. (Author abstract) 8 refs.

**096861 EFFECT OF DOPING ON PARAMETRIC AMPLIFICATION IN PIEZOELECTRIC SEMICONDUCTORS.** Using the straightforward coupled-mode theory, the parameter amplification is analytically investigated in a doped piezoelectric semiconductor. The origin of the nonlinear interaction is taken to be in the second-order optical susceptibility  $\chi^{(2)}$  arising from the nonlinear induced current density. The threshold value of the pump electric field  $E_{0h}$  and the corresponding excitation intensity are obtained for crystals for various concentrations.  $E_{0h}$  is found to decrease with rise in doping concentration. The investigation also reveals that the phenomena of self-focusing and self-defocusing can be enhanced in these crystals. The parametric gain constant is obtained for both lightly and highly doped semiconductors. (Edited author abstract) 17 refs.

**096862 BOLOMETRIC ABSORPTION SPECTRA OF DOPED  $\text{TaS}_3$ .** We have taken bolometric infrared spectra of the charge-density-wave conductor orthorhombic  $\text{TaS}_3$ , doped with niobium and titanium. For transverse polarization, the bolometric signal is roughly proportional to the absorptivity. Niobium doping (approx. 200 ppm) greatly increases the charge-density-wave depinning field and broadens the Peierls transition, while Ti doping (approx. 10 ppm) has negligible effect. Nevertheless, both types of samples have similar spectra: a large decrease of absorption above the Peierls gap (i.e. smearing of the absorption threshold) and no significant increase in absorption below the gap. The 'midgap' absorption line at  $500 \text{ cm}^{-1}$  is not affected by doping. Results are discussed in terms of the model of Tutto and Zawadowski. (Author abstract) 16 refs.

Minton, G. (Univ of Kentucky, Lexington, KY, USA); Brill, J.W. *Solid State Commun* v 65 n 10 Mar 1988 p 1069-1072.

**096863 IMPURITY PAIRING IN THE OPTICAL ABSORPTION OF DOPED SEMICONDUCTORS.** We developed a theoretical approach based on the alternant molecular orbital model for the hydrogen molecule to predict the optical absorption spectrum of donor pairs in doped semiconductors. The fundamental absorption line has been obtained through the density of states in the pair approximation while the interaction between the lattice and the electron excitation has been considered in terms of the Franck-Condon model. (Author abstract) 15 refs.

**096865 FORMATION AND ANALYSIS OF SHALLOW ARSENIC PROFILES.** Shallow arsenic implants were activated by furnace and rapid thermal annealing (RTA). Comparisons of junction depths measured by secondary ion mass spectrometry (SIMS) and spreading resistance (SR) showed SIMS values 50-90 nm deeper than SR values, due to ion knock-on during SIMS profiling. (Author abstract). 7 Refs.

Clayton, S. (Naval Ocean System Cent, San Diego, CA, USA); Springer, L.; Offord, B.; Sedgwick, T.; Reedy, R.; Michel, A.; Scilla, G. *Electron Lett* v 24 n 14 Jul 7 1988 p 831-833.

**096866 INFLUENCE OF EXPERIMENTAL CONDITIONS ON MATRIX EFFECT IN SIMS.** The influence of the experimental conditions on the matrix effect in secondary ion mass spectrometry (SIMS) of Be ions in AlGaAs was investigated with a Cameca IMS-3f ion microanalyzer. In this study the nature and energy of the primary ion beam was varied, as well as the energy filtering and contrast aperture in the secondary optics. A strong influence of the nature of the primary ion and the energy filtering on the matrix effect was found, while the matrix effect was weakly affected by the primary energy and the contrast apertures. The optimum experimental conditions under which the matrix effect was reduced is discussed. 16 Refs.

Gao, Y. (CNET, Bagneux, Fr). *Appl Surf Sci* (1985) v 32 n 4 Aug 1988 p 420-430.

**096867 COUNTERDOPING OF MOS CHANNEL (CDC) - A NEW TECHNIQUE OF IMPROVING SUPPRESSION OF LATCHING IN INSULATED GATE BIPOLAR TRANSISTORS.** A novel technique of improving suppression of latching in insulated-gate bipolar transistors (IGBTs) is proposed and experimentally verified. By counterdoping the channel of the DMOS cell, the doping of the p-base can be increased up to a factor of two. Dynamic latching improvement of 40-80%, corresponding to the p-base doping increase, has been obtained. The degradation in forward blocking voltage was observed when the counterdoping dosage exceeds about  $2 \times 10^{12} \text{ cm}^{-2}$  for 600-V devices. 10 Refs.

**096868 EXTENSION OF THE C-V DOPING PROFILE TECHNIQUE TO STUDY THE MOVEMENTS OF ALLOYED JUNCTION AND SUBSTRATE OUT-DIFFUSION, THE SEPARATION OF JUNCTIONS, AND DEVICE AREA TRIMMING.** Digital data acquisition provides accurate data on capacitance vs. voltage (C-V) measurement and facilitates incorporation of improved analyses based on more complete models. The avalanche field check is an independent means of determining the junction area, and can be used as a quality-control indicator in device production or as a monitoring tool during area trimming of diodes hidden from view. Iterative fitting techniques can yield accuracies sufficient for studying alloyed junction movement from the C-V data. The nature of the doping profile in a nonabrupt junction can be inferred. The profile in the middle layer of a back-to-back junction structure in many practical cases can also be determined. Experimental examples are shown to support the interpretations. 5 Refs.

Tantraporn, W. (GE, Schenectady, NY, USA); Glover, G.H. *IEEE Trans Electron Devices* v 35 n 4 Apr 1988 p 525-529.

**096869 NEW PUNCHTHROUGH CURRENT MODEL BASED ON THE VOLTAGE-DOPING TRANSFORMATION.** The punchthrough phenomenon

is investigated by a 2-D numerical analysis. A physical interpretation that relates this phenomenon to the drain-field-induced reduction in doping concentration is proposed. This interpretation allows a better understanding of the mechanism of surface and bulk punchthrough flows and provides a guideline for the quantitative solution to the problem. The relation between the reduced N<sup>+</sup> and real N dopings (called the voltage-doping transformation, or VDT) is derived from the two-dimensional Poisson equation. It is shown that as a result of the VDT, it is possible to accurately calculate the actual barrier heights as a function of applied voltages and channel length using the well-known long-channel expressions where N is substituted by N\*. 16 Refs.

**096871 SUPERLATTICE DOPING INTERFACES.** The effect of background doping on current transport in quantum well structures is investigated by the use of n<sup>+</sup>-n junctions superimposed on superlattices. Data are presented which show that the applied bias appears across only lightly doped and depleted regions. Current vs. voltage characteristics are observed which are consistent with expected electron barriers for these superlattice structures. Negative differential resistance effects and conductance oscillation effects are also observed, and are shown to originate from movement of bias-dependent depletions. (Author abstract) 10 Refs.

## Drying

**096873 CRITICAL EXAMINATION OF A CRY-CHEMICAL METHOD FOR THE PREPARATION OF HIGH SURFACE AREA SEMICONDUCTING POWDERS.** The effect of the nature of precursor salts on the surface area of mixed metal chlorides and mixed metal oxides prepared by freeze-drying was studied in the following systems: MgCl<sub>2</sub>·6H<sub>2</sub>O-KCl, acetates and nitrates of lanthanum, strontium and cobalt, nitrates of nickel and cobalt. The intermediates as well as the final products were studied by electron microscopy. X-ray powder diffraction, thermogravimetric analysis and differential scanning calorimetry. Dehydration of MgCl<sub>2</sub>·6H<sub>2</sub>O-KCl occurred with an increase in surface area, but any further effects due to the formation of the perovskite phase

were not seen because of sintering. (Edited author abstract) 22 Refs.

## Elasticity

**096874 ELECTRICAL PROPERTIES OF P-TYPE AND N-TYPE ZnSe-ZnTe STRAINED-LAYER SUPERLATTICES.** We have grown ZnSe-ZnTe strained-layer superlattices (SLSs) on InP substrates by molecular beam epitaxy. In addition to undoped SLSs, two kinds of modulation doped SLS samples were prepared in this study. Van der Pauw measurements of the SLS samples at room temperature showed that their electrical properties can be controlled by using the modulation doping technique. The undoped sample and the Ga-doped sample exhibited n-type conduction, whereas p-type conduction was observed for the Sb-doped sample. Interdiffusion profiles of dopants were measured by secondary ion mass spectroscopy, and significant Ga redistribution was observed. Finally, we have fabricated p-n junctions from ZnSe-ZnTe SLSs, and measured their current-voltage characteristics. (Edited author abstract) 12 Refs.

**096875 RESISTIVITY CORRECTION FACTOR FOR FOUR-PROBE METHOD ON CIRCULAR SEMICONDUCTORS - I.** A resistivity correction factor is described for a system consisting of a thick, circular semiconductor and a four-probe array. The electric potentials in the interior of the sample were obtained by solving Poisson's equation analytically. Expressions for the resistivity correction factor are presented for three cases of the probe position. The resistivity correction factors of a circular sheet, calculated by the present method, coincides with that obtained from the conformal transformation method. Numerical evaluations were carried out as a function of the thickness and radius of the sample and the spacing and position of the probe array. (Author abstract) 8 Refs.

**096878 DETERMINATION OF DEGREE OF NON-UNIFORMITY OF RESISTIVITY OVER THICKNESS OF HIGH-RESISTANCE LAYERS.** High-resistance semiconductor layers (i-type layers) are finding wider use, especially in GaAs. They are successfully used as insulation for semiconductor devices and individual components of integrated circuits and as an active region in a number of devices. A method is described for determination of the degree of nonuniformity of resistivity over the thickness of a high-resistance layer that is based on measurement of the frequency dependence of specimen impedance. A computer-based method is proposed for calculation of the resistivity distribution. A circuit is given for measurement of capacitance and loss tangent in the frequency range of  $20\text{--}10^7$  Hz, from which specimen impedance is measured with an error of approximately 15% for R and 5% for X. A graph is given for the resistivity distribution in an i-type layer formed by proton irradiation of n-type GaAs. (Edited author abstract) 7 refs.

**096880 BISTABILITY OF NON-LINEAR CONDUCTIVITY IN INSULATORS WITH SLIDING CHARGE DENSITY WAVES.** At low temperatures in semiconducting compounds with a sliding charge density wave (CDW), it is shown that the nonlinear d.c. current voltage characteristic should be bistable. The high velocity branch describes free sliding of the CDW, motion which becomes undamped at zero temperature ('Froehlich superconductivity'). In the low-velocity branch the CDW is highly deformed, with a velocity low enough that backflow currents of thermally excited quasiparticles can screen the local electric fields produced by the moving CDW. The results are compared with recent experiments on the blue bronze  $\text{K}_{0.3}\text{MoO}_3$ . (Author abstract) 19 refs.

**096885 RESISTIVITY OF SEMICONDUCTOR, SPLIT-ELECTRODE THERMISTORS.** By using Fourier Series Boundary Condition, as well as a standard Fourier series approach to solving Laplace's Equation, an exact solution for the thermistor model was obtained. Then, a PASCAL program was written for a VAX 11/750 computer to evaluate the slowly convergent Fourier series - it being found that fifty terms were required for each resistivity value. Finally, a series of measurements were performed on thermistors of various sizes, and it was found that resistivities calculated with the aid of said resistance measurements were almost invariant, the standard deviation being  $9.148 \text{ ohm-cm}$ , with a mean value of  $\rho = 9.1148 \times 10^2 \text{ ohm-cm}$ . It is clear, that the thermistor model and the methods of solution of the problem were of value. (Edited author abstract) 4 Refs.

**096886 LOCALISATION EFFECT IN THERMO-POWER AND RESISTIVITY OF QUASI 1D SEMICONDUCTING COMPOUND  $[(\text{Nb}_{1-x}\text{Ta}_x\text{Se}_4)_3\text{I}]$ .**  $(\text{NbSe}_4)_3\text{I}$  has a quasi 1D structure consisting of  $\text{NbSe}_4$  chains parallel to the c axis. The Nb-Nb distance within the chain is approx. 3 Å whereas the interchain distance is much larger (6.7 Å). Electrical resistivity and thermoelectric power measurements were carried out in the temperature range 130 K-350 K. For some crystals the low activation energy persists up to the lowest temperature investigated. This was designated type I. For some crystals the activation energy increases once again to a higher value (0.11 eV) at lower temperatures. These crystals were designated type II although X-ray diffraction is unable to distinguish the two types of crystals. The effect of introducing disorder in the chain by introduction of Ta is investigated in the present work. 5 refs.

**096891 QUANTUM CORRECTIONS TO THE HALL EFFECT IN III-V SEMICONDUCTORS.** We have measured the temperature dependence of the low-temperature Hall effect coefficient,  $R_H$ , and resistance, R, of various III-V semiconductors. In 3D when the magnetic field suppresses the quantum interference correction,  $R_H$  and R vary with temperature T as  $T^{1/2}$  in the manner predicted for the electron interaction correction. In samples with a short elastic scattering length, and in the presence of small magnetic fields, we have found a correction to  $R_H$  of approximately the same size but opposite sign to the correction to R. This appears to be a quantum interference correction, which is in disagreement

with theory predicting the absence of such an effect. We suggest that theories of the quantum corrections to the Hall effect require reevaluation in 3D as well as in 2D. (Edited author abstract) 12 refs.

Newson, D.J. (Cambridge Univ, Engl); Pepper, M.; Hall, E.Y.; Hill, G. *J Phys C Solid State Phys* v 20 n 27 Sep 30 1987 p 4369-4376.

**096892 ELECTRIC CONDUCTIVITY AND THERMOELECTRIC POWER OF RARE-EARTH ORTHOCHROMITES OF THE CERIUM SUBGROUP.** Measurements were made of the electric conductivity and thermoelectric power of rare-earth orthochromites in the 870-1270 K range in various gaseous media. It was established that in the  $10^4$ - $10^{12.5}$  Pa, oxygen partial pressure range rare-earth orthochromites remain p-type semiconductors and their electric conductivity depends very little on the oxygen partial pressure in the gaseous phase. It is shown that electrical transport in rare-earth chromites is realized by hole motion (predominantly by electron hopping between chromium ions of different valences). For the first time, a dependence of the electric properties of light rare-earth orthochromites on the atomic number of the lanthanide was noted. 8 refs. In Russian.

**096893 QUICK COMPUTATION OF POTENTIAL DISTRIBUTION IN A HIGHLY CONDUCTIVITY-MODULATED SEMICONDUCTOR AND ITS APPLICATION TO PCD DEVICES.** The plasma-coupled device (PCD), which is a bipolar type functional device, has been applied to various image sensors. However, the PCD patterns cannot be designed by computer simulation because of the difficulty in calculating three-dimensional potential distribution in a highly-injected, highly conductivity-modulated semiconductor body. This letter proposes a new but practical simulation method in which some simple assumptions are employed. It is shown that the shape of the potential distribution and the conductivity modulation region around the ON-element of the PCD are consistent with the experimental observation. (Author abstract) 9 refs.

## Electrochemistry

**096901 PHOTOELECTROCHEMICAL BEHAVIOR OF  $LaCoO_3$  CERAMIC AND SINGLE CRYSTAL.** We report in this paper the electrochemical and photoelectrochemical behavior of  $LaCoO_3$  ceramics and single crystals, as they have recently attracted much attention due to catalytic properties and electrocatalytic influence on oxygen evolution from aqueous solutions. Potentiodynamic sweepings give rise to n-p reversible transitions. Correlations have been established between electrochemical, photoelectrochemical, conductivity mea-

surements and action spectra. Schematic band diagrams have been deduced for n- and p-type material. 13 refs.

Joirot, S. (CNRS, Talence, Fr); Campet, G.; Claverie, J. *Mater Lett* v 6 n 11-12 Oct 1987 p 468-474.

**096902 ORBITAL-ENERGY-RESOLVED PARTIAL CHARGE TRANSFER IN CHEMISORPTION AND ELECTROCHEMICAL PROCESSES ON SEMICONDUCTORS.** The distribution of multi-electron partial charge transfer over the orbital energy scale in chemisorption or electrochemical processes, as revealed by difference density of states calculations, provides basic information about interfacial chemical bonds and is particularly relevant for semiconductors, due to the relation of semiconductor interfacial processes to the band structure and band-gap. A short synopsis of the quantum-chemical approach to electronic structures at electrode interfaces is given in the first part of this paper. In the second part, density of states calculations of the chemisorption on semiconductors at the level of Green's functions of tight-binding Hamiltonians are continued, and the case of chemisorption of water dissociation products ( $H$ ,  $OH$ ) at Ga-terminated GaAs (111)A and (100)A surfaces and their displacement by a halide is reported in some detail. This study contributes data for qualitative distinction of energy-resolved partial charge transfer and surface charging on semiconductor electrodes which is essential for understanding the origin of the dipolar Helmholtz potential. 19 Refs.

## Electrodeposition

**096903 IONIC ELECTRODEPOSITION OF II-VI AND III-V COMPOUNDS. IV. DEPOSITION OF BOTH ELEMENTS AND  $1:1$  COMPOUND POSITIVE OF THE PURE ELEMENT REVERSIBLE POTENTIALS: PURE UNDERPOTENTIAL DEPOSITION.** A description is given of theoretical modeling and computer simulation of electrodeposition of compound semiconductors and addresses the underpotential deposition of both elements and the  $M_1X_1$  compound positive of the free element reversible potential. This is named pure underpotential deposition (PUD) and correspond to Class II compounds as described by F.A. Kroger. PUD occurs when the two reversible (Nernst) potentials are sufficiently close that the elemental activity reductions and free energy change provided by the reaction  $M(s) + X(s) = M_1X_1$ , ( $\Delta G_{MX}^\circ$ ) decrease the anodic terms in the Butler-Volmer equations sufficiently so that the cathodic components cause net deposition of both elements, at comparable rates, positive of where either element individually plates. (Edited author abstract) 16 refs.

**096906 ELECTRON-HOLE LIQUID IN SEMICONDUCTOR SUPERLATTICES OF THE III TYPE.** The coupling energy and the balanced density of an electron-hole liquid are calculated in semiconductor superlattices of the III type which are characterized by an indirect energy slot in the space of the coordinates. (Author abstract) 11 refs.

Markova, N.V.; Silin, A.P. *Sov Phys Lebedev Inst Rep* n 3 1987 p 72-76.

**096907 ELECTRONIC STRUCTURE OF 3D TRANSITION-ATOM IMPURITIES IN SEMICONDUCTORS.** The effects of 3d impurities in semiconductors have preoccupied the field since the invention of the transistor. Reliable experimental data for germanium and silicon became available quite early. Theoretical explanations of the properties of such impurities have lagged behind, in part, because of the inherent complexity of the problem. The article presents an in-depth review of the present status of the field. This review contains a most careful and detailed exposition of various aspects of the subject, presented, as the author states, using 'the combined points of view of theoretical solid-state physics, semiconductor physics, and classical inorganic chemistry'. While all outstanding theoretical issues have not yet been resolved, the article illuminates the great progress that has been made. It should serve as a basic reference and summary to all interested in this subject. 290 refs.

**096908 SELF-ENERGY CORRECTIONS TO THE LOCAL DENSITY BAND STRUCTURE OF SEMICONDUCTORS AND INSULATORS.** A formalism is proposed that allows an efficient computation of the exchange-correlation functional including the nonlocal exchange and dynamical screening correctly. In combination with LDA band structures this functional leads to remarkably good results for semiconductors and even wide gap insulators. The model furthermore provides a qualitative understanding of electronic many-body effects. (Author abstract) 28 refs.

**096909 GROUND STATE OF THE SHALLOW ACCEPTOR IN HIGHLY DOPED P-TYPE  $Hg_{1-x}Mn_xTe$ .** The binding energies of shallow acceptors in  $Hg_{1-x}Mn_xTe$  have been found for several values of  $x$  (from 0.15 to 0.085) using the variational procedure. With a decrease

in composition  $x$  the energy values are slowly decreasing, simultaneously the estimated values of the acceptor polarizability in the ground state are increasing. The Clausius-Mossotti relation and the Castner model of electrostatic impurity-impurity interaction have been applied to evaluated the influence of the polarizability and the neutral acceptor concentration on the reduction of the ground state energy. This influence is significant for high concentrations, especially for smaller values of  $x$ . (Author abstract) 9 refs.

**096912 MONTE CARLO STUDY OF HOT ELECTRON TRANSPORT IN QUANTUM WELLS.** Monte Carlo simulations of hot electron transport in  $AlGaAs/GaAs/AlGaAs$  quantum wells were carried out in order to clarify the drift velocity overshoot and steady state drift velocity versus the electric-field relation. In the simulations, we took into account the nonparabolic isotropic energy band structures. Results are given for  $GaAs$  well widths of 500 and 100 Angstrom and an electron sheet density of  $1.0 \times 10^{12} \text{ cm}^{-2}$  at 77 K. The drift-velocity overshoot reaches about  $7 \times 10^7 \text{ cm/s}$  at an electric field of 10 kV/cm in both quantum well structures. A negative differential mobility appears beyond 3 kV/cm in both structures due to electron transfer from the  $\Gamma$  valley to the L valleys. (Author abstract) 32 refs.

**096913 PIEZORESISTANCE ANISOTROPY OF THE FERROMAGNETIC SEMICONDUCTOR  $HgCr_2Se_4$ .** The spinel  $HgCr_2Se_4$  is a ferromagnetic semiconductor (Curie temperature  $T_C \approx 106K$ ) in which the connection between magnetic and semiconducting properties is notable. Although it has interesting physical properties and a good perspective of practical applications its band structure has not been established up to now. This note report the results of measurements of the anisotropy of the piezoresistance effect in single crystals of n- and p-type  $HgCr_2Se_4$ . These measurements were performed in order to obtain information about the symmetry of the conduction and valence bands in the para- and ferromagnetic regions. 4 Refs.

**096914 TEMPERATURE-INDEPENDENT ELECTRON TRANSFER: RHODAMINE B/ OXIDE SEMICONDUCTOR DYE-SENSITIZATION SYSTEM.** The fluorescence spectrum and decay of rhodamine B (Rh B) adsorbed on insulator ( $SiO_2$ ) and oxide semiconductors ( $ZrO_2$ ,  $TiO_2$  (anatase)) were measured in

vacuo at temperatures in the range 4-300 K. The effect of temperature on both the intensity and decay rates of the fluorescence is very weak, indicating that the electron transfer (ET) from Rh B in the excited state to those semiconductors (SC) is almost an activationless process. The results lead to the conclusion that continuous levels in the conduction band of the SC serve as the electron acceptor state. (Author abstract). 18 Refs.

**096915 MODEL SPECTRAL DENSITY FOR HOT-ELECTRON QUANTUM TRANSPORT.** Quantum transport theory indicates that a proper treatment of high-field transport in semiconductors should include collisional broadening and intracollisional field effects. By using the Generalized Kadanoff-Baym method, we construct a computational scheme which includes both of these effects. The central quantity in our theory is the joint spectral density  $K(k, k')$  which describes the relation between the initial and final kinetic momenta in a scattering event. Analytical and numerical analyses for several models of interest are presented and discussed. (Author abstract). 20 Refs.

Reggiani, Lino (Univ di Modena, Modena, Italy); Lugli, Paolo. *Phys Scr* v 38 n 1 Jul 1988 p 117-121.

**096916 ELECTRONIC STRUCTURE OF (001) FACE CENTERED CUBIC QUASI-PERIODIC SUPERLATTICE.** We study the electronic structure of a (001) face centered cubic quasi-periodic superlattice within a tight binding model using the transfer matrix method and a perturbative approach. The band gaps are found to vary strongly within the two dimensional Brillouin zone and there are a few eigenvalues for each  $k_{11}$  for which the eigenstates appear to be extended in the quasi-periodic direction also. (Author abstract) 6 refs.

**096919 ELECTRONIC STRUCTURE OF II-VI COMPOUNDS AND THEIR ALLOYS - ROLE OF CATION d BANDS.** Traditionally the electronic structure of II-VI compounds was treated theoretically through tight-binding or pseudopotential models, neglecting the cation d bands, despite the fact that they are located less than approximately 10 eV below the valence band maximum (VBM). Applying first-principle all-electron band structure and total energy methods to ZnTe, CdTe, and HgTe and their ordered alloys, we show that inclusion of cation d states on the same footing as other valence states leads to a number of qualitative and quantitative changes in the predicted electronic structure. These include effects on: (i) the predicted band gaps, (ii) the spin-orbit splitting at the VBM, (iii) the band offset between two II-VI compounds, (iv) the cohesive energy, and (v) the direction of charge transfer in an alloy. (Author abstract) 38 refs.

Wei, Su-Huai (Solar Energy Research Inst, Golden, CO, USA); Zunger, Alex. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 1-7.

**096920 OPTICAL AND ELECTRONIC PROPERTIES OF HgTe-CdTe SUPERLATTICES.** A survey of current issues concerning the electronic and optical properties of HgTe-CdTe superlattices is given. The superlattice has been conjectured to provide certain advantages relative to the HgCdTe alloy for infrared detectors. A comparison of theoretical predictions with recent measurements is made. The conduction electrons are expected to be partially localized near the HgTe-CdTe interfaces, to a degree dependent on the superlattice band gap. The valence band offset between HgTe and CdTe is still not determined precisely. Measurements of the optical absorption coefficient as a function of photon energy indicates that expected structure due to energy subbands does occur, indicating the presence of abrupt interfaces. Recent measurements of resonant tunneling currents through double barrier structures also imply abrupt interfaces, and may help in determining the valence band offset. (Author abstract) 11 refs.

Schulman, J.N. (Hughes Research Lab, Malibu, CA, USA). *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 25-27.

**096921 BALLISTIC TRANSPORT IN II-VI SEMICONDUCTOR COMPOUNDS AND ALLOYS.** Realistic band structures are used in calculating the group velocity and scattering rates for electrons with injection energies up to 1 eV in ZnTe, CdTe, and the low-effective-mass alloy  $\text{Hg}_{0.7}\text{Cd}_{0.3}\text{Te}$ . Scattering from longitudinal optical phonons, ionized impurities, and alloy disorder have been included in our full band-structure calculation, which automatically includes both intra- and intervalley scattering. Of the II-VI materials considered, at 77 K HgCdTe is superior for low injection energies (up to 0.25 eV) while CdTe is superior at higher injection energies (1 eV) at room temperature. The attainable mean free paths ( $\geq 1000$  Angstrom) and group velocities ( $\geq 10^8$  cm/s) for both systems are comparable to values found in III-V systems. (Author abstract) 4 refs.

Berding, M.A. (SRI Int, Menlo Park, CA, USA); Krishnamurthy, S.; Sher, A.; Chen, A.-B. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 33-38.

**096922 EXCITON COMPLEXES IN II-VI MATE-**

**RIALS.** Creation and recombination channels of free and bound exciton complexes as well as their interaction mechanisms are discussed for different II-VI compounds to get a survey of general properties of such complexes in these materials. It will be shown that creation of bound excitons in a manifold of excited electronic states plays a dominant role in spectra taken for high excitation densities. The observation of the buildup of biexcitons in two-step processes via bound-exciton levels is demonstrated to be a valuable means to distinguish between these processes and exciton-exciton scattering in II-VI compounds. (Author abstract) 35 refs.

**096924 WIGNER FUNCTION SIMULATION OF QUANTUM TUNNELING.** The quantum mechanical phenomenon of tunneling time has been the subject of much debate. We use a Wigner function description of a Gaussian wave packet to study the tunneling process. By adjusting the parameters of the barrier and wave packet, a variety of cases can be studied. For the multiple barrier case, the tunneling time shows peaks at energies corresponding to resonant states of the system. This charge storage within the well is also found to be significant in studying the resonant tunneling diode, giving rise to kinks in the negative differential conductivity region of the I-V characteristic. (Author abstract) 14 refs.

## Encapsulation

**096926 EFFECT OF HEATING ON THE STRUCTURE OF Au/GaAs ENCAPSULATED WITH  $\text{SiO}_2$ .** The structural effects of heating 1500 Å Au/GaAs (001) encapsulated with 2000 Å of  $\text{SiO}_2$  were examined by scanning electron microscopy and X-ray diffraction. It was observed that  $\text{SiO}_2/\text{Au/GaAs}$  (capped) in vacuum up to 500°C remained shiny and gold in color, whereas similar heating of Au/GaAs (uncapped) caused a change of color from shiny gold to dull silver. Mass spectroscopy showed that the amount of arsenic vapor evolved was much less for the capped sample. However, X-ray diffraction showed that  $\text{Au}_7\text{Ga}_2$  formed abundantly in both types of samples after heating at 500°C, though the epitaxial relationship was mainly  $\text{Au}_7\text{Ga}_2$  (001) || GaAs (001) for capped and  $\text{Au}_7\text{Ga}_2$  (100) || GaAs (001) for uncapped.

SEM revealed gold-rich aligned rectangular protrusions on the surfaces of  $\text{SiO}_2/\text{Au/GaAs}$  as well as Au/GaAs after heating at 500°C, though the average length of these rectangles was 1.5  $\mu\text{m}$  for the capped sample and 6.7  $\mu\text{m}$  for the uncapped sample. New morphological features absent in Au/GaAs were observed in  $\text{SiO}_2/\text{Au/GaAs}$ . These features are a gold-rich maze with a line width of 6  $\mu\text{m}$  and gold-rich protruded lines with a line width of 9  $\mu\text{m}$ . The gold-rich protruded lines were formed by the growth and joining together of some gold-rich aligned rectangular protrusions. The gold-rich maze was observed in  $\text{SiO}_2/\text{Au/GaAs}$  after heating in vacuum, but was not observed in  $\text{SiO}_2/\text{Au/GaAs}$  after heating in nitrogen. (Edited author abstract) 6 refs.

**096929 EFFECT OF DOPANTS CONCENTRATION ON RESOLUTION AND RATE OF LIGHT INDUCED ETCHING - PART I: THEORETICAL ANALYSIS.** Resolving power of light-induced etching (photoetching) for n-type semiconductors is to be understood as including the space-charge region at the surface. The injection modulation characteristic  $\zeta$  is introduced in the proposed model of photoetching. This characteristic is derived from the stationary concentration of holes in case of nonuniform injection; it depends on the semiconductor material characteristics ( $\tau_b$ ,  $N_D$ ,  $L$ ,  $s$ ) and on the light grating period. (Edited author abstract) 14 refs.

**096931 REACTION BETWEEN CdTe AND AQUEOUS SOLUTIONS OF NITRIC ACID.** It is established that the degree of dissolution of CdTe in aqueous solutions of  $\text{HNO}_3$  at 25°C can be judged either from the accumulation of nitric acid reduction products or from the diffusion of oxidation products from the surface of the dissolving plate into the bulk of the solution. On the surface of the plate a film forms which consists of Te,  $\text{TeO}_2$  and, possibly,  $\text{CdTeO}_3$  with a thickness of the order of 1  $\mu\text{m}$ . The formation of a film during the action of nitric acid is attributed to the transfer of  $\text{Cd}^{2+}$  ions of cadmium telluride into the solution and to oxidation of  $\text{Te}^{2-}$  to  $\text{Te}^0$  and  $\text{Te}^{4+}$ . It is concluded that the heterogeneous chemical reaction between CdTe and  $\text{HNO}_3$  may be regarded as the sum of the combined processes of anodic dissolution of tellurium and cathodic reduction of nitric acid. In Russian. 13 refs.

**096935 REACTIVE ION ETCHING OF III-V COMPOUNDS USING  $\text{C}_2\text{H}_6/\text{H}_2$ .** Reactive ion etching of InP, GaInAs and GaAs using a mixture of ethane and hydrogen,  $\text{C}_2\text{H}_6/\text{H}_2$ , is demonstrated for the first time. It has been found that by choosing optimum etching parameters we can obtain excellent vertical sidewalls as well as very smooth surfaces, keeping the etching rate at a convenient value of 20-60 nm/min. (Author abstract). 7 Refs.

Matsui, T. (Mitsubishi Electric Corp, Amagasaki, Jpn); Sugimoto, H.; Ohishi, T.; Ogata, H. *Electron Lett* v 24 n 13 Jun 23 1988 p 798-800.

**096936 WET-CHEMICAL ETCHING OF III-V SEMICONDUCTORS.** III-V semiconductors like GaAs can be wet-chemically etched by three mechanisms: electrochemically with an external voltage source, electrochemically using an oxidizing agent (electroless), and chemically with a reactive compound. In some cases the etching process only proceeds when the semiconductor is exposed to light. The etch rate depends on the relative reaction rate at the semiconductor surface and the mass transfer in the solution. Other important factors are the effect of the crystal planes, the orientation of a mask with respect to these planes, and the electrical contact with other materials. It is pointed out that wet-chemical etching of III-V semiconductors can be used on a large scale for various applications, including the detection of crystallographic defects, the fabrication of special profiles and the selective dissolution of closely related materials in multilayer structures. (Edited author abstract). 16 Refs.

**096937 PROCEEDINGS OF THE SIXTH SYMPOSIUM ON PLASMA PROCESSING.** This conference proceedings contains 60 papers arranged in eight sections. The sections are: processing and degradation; processing, magnetic confinement, reactor design; spectroscopic diagnostics; modeling; damage and deposition; etching of silicon and metals, deposition; surface analysis and interaction and novel applications of plasmas. The topics discussed are dry etching, reactive ion etching, resist etching, sloped contact etch process in a single wafer, multilevel VLSI metallizations, plasma processing, surface modifications produced by etching, chemical sputtering of semiconductors, ion suppression, and laser assisted plasma etching. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10842 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

Mathad, G.S. (Ed.) (IBM, East Fishkill, NY, USA); Schwartz, G.C. (Ed.); Gottscho, R.A. (Ed.). *Proc Electrochem Soc* v 87-6, Proc of the Sixth Symp on Plasma Process, San Diego, CA, USA, Oct 19-24 1986. Publ by Electrochemical Soc Inc, Pennington, NJ, USA, 1987 754p.

**096938 PREPARATION DE SURFACE DES COMPOSES III-V PAR GRAVURE IONIQUE REACTIVE DANS UN MELANGE GAZEUX A BASE DE METHANE.** [Surface Preparation of III-V Compounds by Reactive Ion Etching in a Methane-Based Gas Mixture]. Dry etching techniques are becoming increasingly important, and recently a Metal Organic Reactive Ion Etching (MORIE) process usable in micro-opto-electronic technology has been reported. This process appears usable also for surface treatments; for example, before epitaxial growth. (Author abstract) 4 refs. In French.

## Evaporation

**096939 THERMOGRAVIMETRIC AND MASS-SPECTROMETRIC STUDIES OF  $\text{Cd}_4\text{GeSe}_6$  AND  $\text{Cd}_4\text{GeSe}_5$ .** A thermogravimetric study of the  $\text{Cd}_4\text{GeSe}_6$  and  $\text{Cd}_4\text{GeSe}_5$  powders showed that these materials are stable during heating in air to 680 and 740 K, respectively. Evaporation of the compounds is of incongruent character, and the degree of dissociation depends on the temperature of the evaporator. In the vapor phase of the compounds  $\text{CdS}$ ,  $\text{CdSe}$ ,  $\text{GeSe}_2$  and  $\text{GeSe}$  molecules are observed which are elements of the crystal structure. Molecules which include germanium and cadmium atoms simultaneously are not presented. In Russian. 6 refs.

## Friction

**096940 FRICTION AND WEAR OF SEMICONDUCTORS IN SLIDING CONTACT WITH PURE METALS.** The friction and wear of the semiconductors silicon and gallium arsenide in contact with pure metals was studied. Friction experiments were conducted at room temperature in air and in a vacuum of  $2.0 \times 10^{-7}$  Pa. Five transition and two nontransition metals - titanium, tantalum, nickel, palladium, platinum, copper, and silver - were slid on a single crystal of silicon. Four metals - indium, nickel, copper, and silver - were slid on a single crystal of gallium arsenide. Furthermore, experiments on the wear of silicon in sliding contact with titanium, nickel, and copper were conducted in a vacuum of  $1.0 \times 10^{-5}$  Pa. The results indicated that the friction and wear of the semiconductors were dependent on the contacting metal. The effect of the contacting metal on the friction and wear was considered to arise from the interactions at the metal-semiconductor interface. (Edited author abstract) 22 refs.

## Grain Boundaries

**096941 TRANSIENT PHOTOCONDUCTIVITY ANALYSIS NEAR A GRAIN BOUNDARY OF POLYCRYSTALLINE SEMICONDUCTORS.** The effect of grain boundary recombination on the photoconductance transient response, after excitation with a delta function light pulse near a grain boundary, is studied here. An analytical expression is derived for this decay which can be readily computed numerically. The photoconductance turns out to be a non-exponential function of time even at large decay times. A practical method, based on such non-experimental decay curves obtained with the light beam positioned away or near a grain boundary, is developed to deduce accurate values of the bulk lifetime and in the grain boundary recombination velocity. (Author abstract) 16 refs.

**096942 MOVPE GROWN  $\text{GaAlAs/GaAs}$  DH DEVICES OPERATING AS LASER DIODES AND BIPOLAR TRANSISTORS FOR OPTOELECTRONIC INTEGRATION.** In these devices, a structural similarity between DH (double-heterostructure) laser diodes and DH bipolar transistors has been taken full advantage of, since both laser diodes and electronic devices can be fabricated simultaneously in the same process, using an epitaxial wafer grown in one step. The function of the devices is described. A maximum current gain of 5000 was observed with typical values in the range of 200-1000 for a collector current density  $J_c$  of 2  $\text{kA/cm}^2$ . This result is a substantial improvement over results previously reported. This is because the setback layers avoid the displacement of the emitter-base p-n junction. When the device operates as a laser diode between the emitter-base junction, a lasing characteristic with a minimum threshold current  $I_{th}$  of 170 mA and a differential quantum efficiency of about 10% at room temperature are obtained. The main reason for the rather high  $I_{th}$  is the leakage current through the  $\text{GaAlAs}$  p<sup>+</sup>-n homojunction. Optimization of the device structure - for example, by increasing the aluminum content in the cladding layers and using the quantum well base structure is expected to produce a lower lasing threshold current. 1 ref.

**096943 GROWTH AND STRUCTURAL CONSIDERATIONS ON SINGLE TIBISE<sub>2</sub> CRYSTALS.** TIBISE<sub>2</sub> single crystals were grown in an adequate size (2 cm long and 1 cm diameter). The material was characterized by X-ray powder diffraction and electron microscopy. TIBISE<sub>2</sub> crystallizes with rhombohedral symmetry, forming a slightly distorted cubic lattice with a nonprimitive unit cell of  $a=6.162$  Å and  $\alpha=87.21^\circ$ . Ordering of Ti and Bi layers perpendicular to the [111] direction leads to superstructure reflections, only observed in the electron diffraction patterns. A high density of regularly arranged or movable dislocations was also observed. (Author abstract) 23 refs.

**096945 GROWTH AND SOME PROPERTIES OF Zn<sub>2</sub>In<sub>2</sub>S<sub>8</sub> SINGLE CRYSTAL.** Zn<sub>2</sub>In<sub>2</sub>S<sub>8</sub> has been synthesized in the form of single hexagonal platelets. This compound is the fifth member of the layered semiconductor family Zn<sub>x</sub>In<sub>2-x</sub>S<sub>8</sub>. Optical measurements are used for the evaluation of the energy gap at room temperature. This was found equal to 2.84 eV. The presence of extended composition faults was indicated by the a<sup>2</sup>-hv diagrams and proved by electron microscopy techniques. Some electrical properties have been studied and an electron trap at  $E_t=E_c-0.4$  eV, with a concentration of about  $10^{12}$  cm<sup>-3</sup> was found to exist. An anisotropy of about  $10^6$  was measured in the two directions: parallel to the layers and vertical to them. (Edited author abstract) 13 refs.

Kalomiros, J.A. (Aristoteles Univ of Thessaloniki, Thessaloniki, Greece); Anagnostopoulos, A.N.; Spyridelis, J. *Mater Res Bull* v 22 n 10 Oct 1987 p 1307-1314.

**096946 METAL-ORGANIC VAPOUR-PHASE EPITAXY OF MULTILAYER STRUCTURES WITH III-V SEMICONDUCTORS.** Vapor-phase epitaxy with metal-organic reactants (MO-VEP) is a method for growing multilayer structures of III-V semiconductor materials such as GaAs and Al<sub>x</sub>Ga<sub>1-x</sub>As. Precise control of the growth parameters can give interfaces that are abrupt on an atomic scale. The quality of the interfaces and the depth profiling have been assessed by spectroscopic ellipsometry and confirmed by photoluminescence experiments on quantum wells consisting of a thin GaAs layer between two Al<sub>x</sub>Ga<sub>1-x</sub>As layers with a larger band gap. The emission wavelength of these wells can be varied in a controlled manner from 800 to 620 nm by decreasing the well width or incorporating aluminum in the well, or both. Laser operation has been obtained for quantum wells with emission wavelengths down to 730 nm. In modulation-doped heterostructures with GaAs and Al<sub>x</sub>Ga<sub>1-x</sub>As a two-dimensional electron gas is formed on the GaAs side near the heterojunction. The spatial separation of carriers and donor impurities gives high electron mobilities, particularly at low temperatures. This favors the application of such structures for obtaining transistors

with a good high-frequency performance. At low temperatures the presence of a two-dimensional electron gas is responsible for the 'quantized Hall effect.' (Edited author abstract) 23 refs.

Frijlink, P.M. (Lab d'Electronique et de Physique Appliquee, Limeil-Brevannes, Fr); Andre, J.P.; Erman, M. *Philips Tech Rev* v 43 n 5-6 May 1987 p 118-132.

**096947 METAL-ORGANIC VAPOUR-PHASE EPITAXY WITH A NOVEL REACTOR AND CHARACTERIZATION OF MULTILAYER STRUCTURES.** A novel type of reactor has been developed for making MO-VEP multilayer structures, in which sharp transitions can be obtained between layers of different composition. The perfection of the structures produced is demonstrated by means of transmission electron microscopy. It is demonstrated for instance that the transition regions are no thicker than approximately one monolayer. The optical quality of the quantum wells is determined by measuring the decay time of the luminescence. It appears that the decay time in quantum wells is less dependent on temperature than in bulk material, so that the threshold current for laser operation is also less temperature-dependent. (Edited author abstract) 10 refs.

Leys, M.R. (Philips Research Lab, Eindhoven, Neth); Viegiers, M.P.A.; 't Hooft, G.W. *Philips Tech Rev* v 43 n 5-6 May 1987 p 133-142.

**096948 MOLECULAR BEAM EPITAXY OF MULTILAYER STRUCTURES WITH GaAs AND Al<sub>x</sub>Ga<sub>1-x</sub>As.** The growth of thin films of GaAs and Al<sub>x</sub>Ga<sub>1-x</sub>As on GaAs substrates by molecular beam epitaxy (MBE) has been investigated. High-quality films and multilayer structures with controlled thickness and composition have been deposited. Information has been obtained on the surface chemistry and the dynamics of growth. It is possible to produce abrupt interfaces between GaAs and Al<sub>x</sub>Ga<sub>1-x</sub>As layers, where the compositional changes occur over no more than one monolayer. GaAs layers have been grown with low background impurity concentrations ( $2 \times 10^{14}$  cm<sup>-3</sup>) and this has enabled us to achieve high electron mobilities at low temperatures ( $3 \times 10^6$  cm<sup>2</sup>V<sup>-1</sup>s<sup>-1</sup> at 4 K) in two-dimensional electro-gas structures. Multiple quantum-well structures prepared by growing very thin GaAs wells between Al<sub>x</sub>Ga<sub>1-x</sub>As barriers showed laser emission at wavelengths down to 704 nm. (Edited author abstract) 27 refs.

**096949 TEM INVESTIGATIONS OF THE TUNGSTEN SILICIDE FILMS ON SILICON.** Tungsten silicide thin films were prepared by electron beam evaporation techniques. Tungsten films of 900 Å thick were evaporated onto the silicon substrates. The as-deposited films were subsequently annealed in a quartz diffusion furnace under an N<sub>2</sub> atmosphere. X-ray diffraction and transmission electron microscopy were used to determine the structure of the annealed thin films. Grain coarsening and epitaxial silicides were observed on the as-deposited tungsten film on (100) silicon after furnace annealing at 800°C for 1 hour. (Author abstract) 12 refs.

**096950 SPARK SOURCE MASS SPECTROGRAPHIC ANALYSES OF α-HgI<sub>2</sub>.** The concentrations of both inorganic and organic impurities in α-HgI<sub>2</sub> single crystals grown in different laboratories, in solution or from the vapor phase, have been analyzed by SSMS. The total content of carbon in hydrocarbons is very high, ranging from about 30 up to 50,000 at.ppm, most crystals containing several thousands of ppm. Li, Bi, C, F, Na, Mg, Al, Si, P, S, Cl, K, Ca, Ti, V, Cr, Mn, Fe, Ni, Co, Cu, Zn, As, Br and Ag are characteristic inorganic impurities. Al, Cl and K have the highest concentrations of up to hundreds of at.ppm. Na, Mg, Si, S, Ca, Fe and Br concentrations reach tens of ppm. The others have concentrations of the order of ppm. Most impurities are concentrated in clusters. There is a straightforward

correlation between the SSMS data and the nuclear detector quality of crystals. (Author abstract) 32 refs.

**096952 ISOTHERMAL MOTION IN A LIQUID-ENCAPSULATED CZOCHRALSKI CRYSTAL PULLER WITH AN AXIAL MAGNETIC FIELD.** During the growth of a semi-conductor crystal in a Czochralski crystal puller, the time periodic convection and turbulence are suppressed by an applied magnetic field. The velocities in the molten material are decreasing functions of the magnetic field strength. For the growth of gallium arsenide, a liquid bulk encapsulant is added over the free surface of the melt to prevent the evaporation of arsenic. The encapsulant and melt motion are coupled through the boundary conditions at the liquid-liquid interface, providing a mechanism for meridional circulations in the melt which are not present in non-encapsulated systems. This paper presents analytical solutions for an isothermal liquid-encapsulated GaAs system with a strong, uniform axial magnetic field. (Author abstract) 6 refs.

**096953 ESTIMATION OF MINIMUM GROWTH TEMPERATURE FOR CRYSTALS GROWN FROM THE GAS PHASE.** It is proposed that the limiting temperature,  $\theta$ , for single crystal growth from the gas phase is the temperature at which the kinetic rate of arrival at each surface site is equal to the rate of removal by surface diffusion. An expression is derived for  $\theta$  at atmospheric pressure. Surface diffusion is considered for the cases of covalent, ionic and metallic solids, and simple models used to allow the estimation of activation energy for surface diffusion in each case. Results are presented for 33 crystals including group IV elements, III-V compounds ionic solids and metals. Agreement with experimental results is shown to be satisfactory in those cases where results are available from the literature. (Edited author abstract) 20 refs.

**096955 ALTERNATIVE PRECURSORS FOR THE MOVPE GROWTH OF WIDE BAND GAP II-VI COMPOUNDS.** The use of conventional precursors such as dialkylzinc compounds and group VI hydrides has traditionally caused serious pre-reaction problems in the growth of wide band gap II-VI materials, (e.g., ZnSe and ZnS), by MOVPE. There is thus a need for alternative source materials. One solution has been to employ alkyl- or heterocyclic derivatives of the group VI elements and this work is briefly reviewed here. An alternative approach is to modify the group II source to make it less susceptible to pre-reaction with the group VI hydride. We now report the successful use of the 1,4-dioxan and 1,4-thioxan adducts of dimethylzinc as precursors for high quality ZnSe. In addition to reducing significantly the pre-reaction with 2Se the use of these adducts allows epitaxial growth of ZnSe at temperatures as low as 200°C. (Author abstract) 21 refs.

**096956 PURIFICATION OF GROUP III METAL ALKYLs USING NITROGEN DONOR LIGANDS.** Increased understanding of the factors affecting adduct formation between group III metal alkyls (Lewis acids) and group V Lewis bases, and their subsequent thermal behavior, have led directly to the discovery of a new process for the purification of group III metal alkyls e.g.  $\text{Me}_3\text{M}$  (M=Al, Ga and In) and  $\text{Et}_3\text{In}$ . This process involves the formation of involatile adducts of the metal alkyls with the involatile diamine 4,4'-methylenebis(N,N'-dimethylaniline) (Arnold's base,  $[\text{Me}_2\text{N}(\text{C}_6\text{H}_4)]_2\text{CH}_2$ , MBDA) which dissociate on heating in vacuo to liberate the high purity metal alkyl. Samples of the alkyls have been analyzed for microimpurities by Inductively Coupled Plasma Emission Spectroscopy (ICP) before and after purification in order to probe the effectiveness of the new process. Vapor pressure measurements of trimethylindium over the adduct  $(\text{Me}_3\text{In})_2\text{MBDA}$  have been carried out in order to investigate the potential of this adduct for the delivery of trimethylindium by the modified entrainment method. (Author abstract) 24 refs.

Foster, Douglas F. (Univ of St. Andrews, St. Andrews, Scotl); Rushworth, Simon A.; Cole-Hamilton, David J.; Jones, Anthony C.; Stagg, John P. *Chemtronics* v 3 n 1 Mar 1988 p 38-43.

**096957 REAGENT CONCENTRATION MEASUREMENTS IN METAL ORGANIC VAPOUR PHASE EPITAXY (MOVPE) USING AN ULTRASONIC CELL.** An ultrasonic cell for measuring gas composition is described. Measurements were made of steady-state partial pressures of trimethyl gallium (TMG) and trimethyl indium (TMI), at  $25\text{ cm}^3\text{ min}^{-1}$  hydrogen flow-rate, as a function of temperature of the sources. The following partial pressure equations were found to apply. For TMG:  $\log_{10} P$  (Torr)  $8.05-1710/T(\text{K})$  for  $-10.6^\circ\text{C} < T(\text{K}) < 11.0^\circ\text{C}$  TMI:  $\log_{10} P$  (Torr)  $= 11.14-3240/T(\text{K})$  for  $-7.7^\circ\text{C} < T < 70.4^\circ\text{C}$ . The ratio of principal specific heats, for the two alkyl vapors were found to be:  $\gamma(\text{TMG})=1.103\pm 0.003$  and  $\gamma(\text{TMI})=1.12\pm 0.025$ . Observations that the partial pressure can depend on the temperature at which the TMI was condensed suggest dimorphism of TMI. (Author abstract) 25 refs.

**096958 DISSOCIATION PRESSURES OF SOME GROUP III TRIALKYLs OVER THEIR ADDUCTS WITH 1,2-BIS(DIPHENYLPHOSPHINO) ETHANE.** The dissociation pressures of trimethyl aluminum ( $\text{Me}_3\text{Al}$ ), trimethyl gallium ( $\text{Me}_3\text{Ga}$ ), deuterotrimethyl gallium ( $\text{CD}_3)_3\text{Ga}$  and trimethyl indium ( $\text{Me}_3\text{In}$ ), over their respective adducts with 1,2-bis(diphenylphosphino) ethane  $\text{Ph}_2\text{P}(\text{CH}_2)_2\text{PPh}_2$  have been determined by Knudsen mass loss effusion. The enthalpy changes for these processes were found to be in the order  $\text{Me}_3\text{Al} > \text{Me}_3\text{In} > \text{Me}_3\text{Ga} \approx (\text{CD}_3)_3\text{Ga}$ . (Author abstract) 15 refs.

**096960 SIMULATION OF III-V TERNARY COMPOUND SEMICONDUCTOR MATERIAL GROWTH BY LIQUID PHASE EPITAXIAL TECHNIQUE.** A calculation method is developed to simulate the liquid phase epitaxial (LPE) growth of III-V compound semiconductors. The semiconductors under simulation are the ternary materials  $\text{AlGaAs}$ ,  $\text{InGaAs}$  and  $\text{InAsSb}$ . There are melt back and lattice mismatch problems to grow a  $\text{InAs}_{0.35}\text{Sb}_{0.65}$  epilayer on  $\text{InSb}$  substrate. Simulation results suggest that this can be achieved by proper preparation of melt and temperature programming. (Author abstract). 24 Refs.

Cheng, Chih-ho (Nat'l Tsing Hua Univ, Hsin-Chu, Taiwan); Hsueh, Kan-Lin; Yang, Chien-Wen; Lien, Chen-sin. *Chemtronics* v 3 n 2 Jun 1988 p 94-98.

**096961 MICROSCOPY OF BULK-GROWN III-V SEMICONDUCTOR MATERIALS.** Compounds formed by the combination of one or more of the elements from Group IIIA (Al, Ga, or In) and Group VA (P, As, or Sb) are known as III-V materials. These materials have attractive semiconductor properties, but much of their potential has yet to be realized because they are difficult to produce in high-quality single crystal form. The purpose of this review is to describe how microscopy based studies have influenced the development of III-V materials, with particular emphasis on the impact such studies have had on materials applications. The review is concerned with materials produced by bulk growth methods in which large volumes of single crystal material are grown. The currently important materials are discussed with reference to the specific material properties that are attractive for a particular application. 126 refs.

**096962 NEW DEVELOPMENTS IN IIa-VIb (ALKALINE-EARTH CHALCOGENIDE) BINARY SEMICONDUCTORS.** Single crystals of Ca, Sr and Ba monochalcogenides have been grown by a floating melt-zone method. Reflection, luminescence and other optical spectra have been measured on these high quality crystals. From experimental and theoretical studies on the band structure, it is concluded that most of these IIa-VIb crystals are indirect gap semiconductors (except BaO) with the minimum gap between the X-point conduction band and the  $\Gamma$ -point valence band. This indirect gap is predicted to be dipole-forbidden from the symmetry of the X-point phonons. Such a specific feature in the band structure of IIa-VIb crystals is supposed to have a significant influence on the optoelectronic properties of IIa-VIb compound semiconductors. (Author abstract) 12 refs.

Kaneko, Yoshio (Univ of Tokyo, Tokyo, Jpn); Koda, Takao. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 72-78.

**096963 GROWTH AND CHARACTERIZATION OF  $\text{Cd}_{1-x}\text{Zn}_x\text{Te}$  AND  $\text{Hg}_{1-x}\text{Zn}_x\text{Te}$ .** We describe the modified vertical Bridgman conditions required for bulk growth of  $\text{Cd}_{1-x}\text{Zn}_x\text{Te}$  and  $\text{Hg}_{0.87}\text{Zn}_{0.13}\text{Te}$ . Good quality single crystals were obtained, with dislocation densities of approximately  $4 \times 10^4$  to  $1 \times 10^5\text{ cm}^{-2}$ . No

precipitates were observed under IR microscopic examination. The  $\text{Hg}_{0.87}\text{Zn}_{0.13}\text{Te}$  crystal exhibited n-type behavior after a 250°C mercury saturated post-anneal, with a carrier density of  $8 \times 10^{15}\text{ cm}^{-3}$  and mobility of  $1.5 \times 10^5\text{ cm}^2/\text{V}\cdot\text{s}$  at 77 K. X-ray lattice constant measurements and atomic absorption analysis were used to establish accurately the zinc mole fraction in the crystals. The structural properties were studied using X-ray diffraction and topography; photoreflectance, a contactless form of the electric field modulated reflectivity technique, was used for optical characterization. (Author abstract) 13 refs.

**096964 INTERNAL TEMPERATURE GRADIENT OF ALLOY SEMICONDUCTOR MELTS FROM INTERRUPTED GROWTH EXPERIMENTS.** Interrupted growth experiments on  $\text{Hg}_{0.8}\text{Cd}_{0.2}\text{Se}$  alloys were performed in an attempt to estimate the actual internal temperature gradient in the melt during directional solidification. The results have been analyzed in terms of a theoretical model which assumes an axial composition profile characteristic of diffusion controlled solute redistribution during growth. A comparison of the calculated and measured values suggests a reduction in the applied (empty furnace) temperature gradient by about a factor of three. Values of the interface segregation coefficient ( $k$ ) determined from the phase diagram, predict values of solute concentration build up in the solid during growth interruptions which are inconsistent with measured results. It appears that the  $k$  values used tend to underestimate the actual  $k$  values for higher alloy compositions and overestimate  $k$  for the lower alloy compositions. (Author abstract) 8 refs.

Andrews, R.N. (Univ of Alabama at Birmingham, Birmingham, AL, USA); Szofran, F.R.; Lehoczy, S.L. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 100-105.

**096965 REVIEW OF THE BULK GROWTH OF HIGH BAND GAP II-VI COMPOUNDS.** A wide variety of methods has been applied to the bulk growth of high band gap II-VI compounds. This is due in part to the differences between the compounds, but more importantly, to the great difficulty of achieving single crystal material of significant size. Melt, solution, and vapor methods have all yielded material useful for small-scale experimental studies; however, significant progress in skill needs to be made in growth techniques for future applications of II-VI compounds to become effective. (Author abstract) 48 refs.

Fitzpatrick, B.J. (Philips Corp, Briarcliff Manor, NY, USA). *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 106-110.

**096966 RECENT DEVELOPMENTS IN  $\text{HgCdTe}$  AND  $\text{HgZnTe}$  GROWTH FROM Te SOLUTIONS.** Growth of  $\text{HgCdTe}$  by liquid phase epitaxy (LPE) from Te-rich solutions has become a widely used approach to produce large-area films with good crystalline quality. This approach offers several advantages, namely, a low Hg overpressure, simplicity of growth chamber design, and reduced solute depletion from the melt. This paper briefly reviews some of the recent progress in growing LPE from Te rich melts and compares it with alternative epitaxial growth techniques. In addition, it will address doping

HgCdTe LPE with group Va impurities and growth of HgZnTe as a possible emerging alternative to HgCdTe. (Author abstract) 19 refs.

Castro, C.A. (Texas Instruments Inc, Dallas, TX, USA); Tregilgas, J.H. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 138-145.

**096967 INFINITE-MELT VERTICAL LIQUID-PHASE EPITAXY OF HgCdTe FROM Hg SOLUTION: STATUS AND PROSPECTS.** Liquid-phase epitaxy (LPE) has emerged as the predominant materials growth technology for the fabrication of HgCdTe infrared (IR) detectors in the IR community over the past decade. This paper reviews the current status as well as the evolution of one modification of LPE technology, specifically, 'infinite-melt' vertical LPE (VLPE) from Hg-rich solutions. The backside-illuminated hybrid focal plane array (HFPA) approach for IR detection has been established in the past few years as the most attractive one for both scanning and staring modes in either tactical or strategic applications. Knowledge of fundamental material properties for the Hg-Cd-Te system is reviewed in three main areas: phase diagram, defect chemistry, and impurity doping. The review concludes with a discussion of the prospects for use of the VLPE technology for investigating fundamental material properties of HgCdTe as well as fabricating advanced device structures of high performance. (Edited author abstract) 54 refs.

**096968 TERRACING IN HgCdTe LPE FILMS GROWN FROM Te SOLUTION.** Terracing in HgCdTe films grown by LPE from Te solution is influenced by many factors. These include melt-back of the substrate, substrate holder design, rotation rate of the substrate, thermal gradients, and growth rates. Many of the variables which influence terracing are interdependent and can be related to their effects on the supersaturation. Variables which tend to level the solute and/or thermal fields would tend to reduce terracing. (Author abstract) 12 refs.

**096969 SEMICONDUCTOR QUANTUM WELL STRUCTURES AND SUPERLATTICES, SYMPOSIUM.** This conference proceedings contains 37 papers, 2 are in abstracted form only. The main subjects are thin-film growth techniques, molecular beam epitaxy (MBE), metalorganic vapor phase epitaxy (MOVPE), hot wall epitaxy (HWE), ultrathin multilayer structures, quantum well heterostructures, artificial superlattices, strained-layer superlattices, bandgap engineering and band structure, integrated optics, and magnetic epitaxial structures. Assessment techniques of ultrathin multilayer structures are also presented, of particular importance is the microscopic structure at the interface of the constituent layers. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11465 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**096972 ANALYSIS OF THERMIONIC EMISSION CURRENT OVER THE AL<sub>1-x</sub>Ga<sub>x</sub>1-xAs BARRIER IN A GaAs/Al<sub>1-x</sub>Ga<sub>x</sub>1-xAs/GaAs (x > 0.45) STRUCTURE.** Thermionic emission (TE) current over the Al<sub>1-x</sub>Ga<sub>x</sub>1-xAs barrier in a GaAs/Al<sub>1-x</sub>Ga<sub>x</sub>1-xAs/GaAs (x > 0.45) structure has been analyzed taking into account the conduction band structures of GaAs and Al<sub>1-x</sub>Ga<sub>x</sub>1-xAs. Assumption of a noninteracting electron model leads to the conclusion that the L valley governs the TE current. This is true for x > 0.45, but contradicts recent experiments when x approaches 1. The model has been modified to include the  $\Gamma \rightarrow X \rightarrow \Gamma$  current which arises from the mixing between  $\Gamma$  and X wave functions at heterojunction interfaces. On the basis of the modified model, the competition between the L current and the  $\Gamma \rightarrow X \rightarrow \Gamma$  current is discussed. (Author abstract) 10 refs.

**096974 STUDY ON COPPER VALENCY OF HIGH-T<sub>c</sub> SUPERCONDUCTOR YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7-y</sub> BY HIGH TEMPERATURE X-RAY ABSORPTION SPECTROSCOPY.** The X-ray absorption spectra of the Cu K-edge have been obtained for a high-T<sub>c</sub> superconductor YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7-y</sub> by in-situ high temperature measurements between room temperature and 600°C and for quenched samples prepared by rapid cooling from various temperatures up to 880°C. The results indicate that the copper valency is predominantly 2+ and the monovalent state appears as the oxygen contents decrease with

increasing temperature. The Cu K-edge X-ray absorption spectra of lanthanide compounds with oxygen-deficient triperovskite structure LnBa<sub>2</sub>Cu<sub>3</sub>O<sub>7-y</sub> (Ln=Nd, Sm, Eu, Gd, Dy, Ho, Er, Tm, Yb or Lu) were also reported. (Author abstract) 29 refs.

**096975 OXYGEN EVOLUTION FROM YBa<sub>2</sub>Cu<sub>3</sub>O<sub>6.85</sub> HIGH T<sub>c</sub> SUPERCONDUCTORS.** Neutron and X-ray diffraction experiments showed the relation between the oxygen content and the structural phase transition in high temperature superconductors. We report on measurements of the oxygen desorption in YBa<sub>2</sub>Cu<sub>3</sub>O<sub>6.85</sub> using high temperature oxygen evolution techniques, and find quantitative agreement with neutron diffraction data. Below 800°C the expansion coefficient is related to the evolution rate. Using desorption relations we assign a value of 0.16 eV to the oxygen-oxygen repulsion energy, responsible for the order-disorder transition in the linear Cu-O chains. Above 800°C several sharp oxygen escape peaks are observed. (Edited author abstract) 16 refs.

**096976 HALL EFFECT MEASUREMENTS IN La<sub>2-x</sub>Sr<sub>x</sub>CuO<sub>4</sub>.** We present Hall effect measurements in the normal state of the high temperature superconducting ceramics La<sub>2-x</sub>Sr<sub>x</sub>CuO<sub>4</sub> (x=0, 0.05, 0.08, 0.1, 0.15, 0.2, 0.25 and 0.30). The Hall constant (R<sub>H</sub>) is positive and it is a decreasing function of x. Every Sr gives approximately 1 hole to the conduction band. For x=0, R<sub>H</sub> has semiconductor-like temperature dependence, while for the other Sr concentrations, R<sub>H</sub> is constant in temperature. The Hall mobility ( $\mu_H$ ) decreases with x at high temperatures. For x=0  $d\mu_H/dT > 0$  and with doping it changes to  $d\mu_H/dT < 0$ . We give a simple model calculation which qualitatively accounts for the observed behavior of the resistivity, Hall constant and Hall mobility as a function of Sr concentration. (Author abstract) 12 refs.

**096977 LO-PHONON MODES BOUND TO NEUTRAL IMPURITIES IN POLAR SEMICONDUCTORS: II. SPECIAL CASES AND EXPERIMENTAL RESULTS.** In a previous paper the Froehlich interaction between charge carriers bound at impurities and LO-phonons in polar semiconductors was considered within second-order perturbation theory. Here special cases including the possibilities of degenerate electronic ground and excited states are discussed. Jahn-Teller like splittings of degenerate ground states as well as Lamb-Rutherford like splittings of degenerate excited states are obtained. Besides renormalized electronic excitations the solution of the eigenvalue problem yields phonons bound to neutral impurities (dielectric modes). Results of Raman spectroscopic determinations of these modes in GaP, Si, and

Sn are presented and their experimental binding energies are compared with theoretical results. (Author abstract) 18 refs.

**096978 THEORETICAL INVESTIGATION OF DEEP-LEVEL IMPURITIES IN SEMICONDUCTORS CHROMIUM AND MANGANESE IN GaAs.** A general theoretical discussion is given of the properties of defect atoms in semiconducting crystals. The calculations begin from a Hamiltonian of the electrons in a perfect semiconductor crystal containing one defect atom. By a series of transformations, it is found that the admixtures of the band and defect states are small when the electron defect states are in the middle of the band gap. In contrast, when the electron energies of the defect states are close to those of the band, much admixing takes place and the localized states become delocalized. The results are used to illustrate in a qualitative way the differences in properties between  $Mn^{3+}$  and  $Cr^{3+}$  ions in GaAs, and to re-examine the luminescence properties of chromium-doped GaAs. (Author abstract) 22 refs.

**096980 TWO-DIMENSIONAL ELECTRON GAS OF VERY HIGH MOBILITY IN PLANAR DOPED HETEROSTRUCTURES.** We demonstrate how it is possible to optimize the reduction of remote ionized impurity scattering in modulation doped heterostructures. This can be obtained by a novel implementation of the doping in the barrier using two planar doped layers separated by a large spacer. We have verified this prediction in GaAs/GaAlAs heterojunctions and obtained in preliminary studies very high mobilities reaching a peak value of  $3.7 \times 10^6 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$  at a sheet electron density of  $1.8 \times 10^{11} \text{ cm}^{-2}$ . (Author abstract) 10 refs.

**096981 ISOELECTRONIC SUBSTITUTIONAL IMPURITY-INDUCED OPTICAL ABSORPTION IN AN NaCl-TYPE SEMICONDUCTOR.** The structures in the complex dielectric function of an isoelectronic substitutional dilute alloy have been analyzed in terms of extra and missing wavevector conserving transitions. Wavevector non-conserving transitions have not been pointed out for an s conduction band and a p valence band with NaCl structure. The transitions are related to the modification of the host density of states due to the impurity potential. The lowest-energy direct transitions give rise to a structure which can be used to determine or to confirm the band gap energy. The other transitions serve to investigate critical points in the Brillouin zone. (Author abstract) 4 refs.

**096983 DENSITY-OF-STATES DUE TO PAIRING OF IMPURITIES IN SEMICONDUCTOR SYSTEMS.** We study the pair formation of hydrogen-like impurities in 3-D and 2-D systems. The density-of-states is obtained for the ground state of the  $H_2$ -like molecule and  $H_2^+$ -like ion for concentrations realizable in doped semiconductors and MOS structures. The joint density-of-states for the transition  $H_2 \rightarrow H_2^+$  is also obtained. The calculated bandwidth shows that pair formation is relevant in those systems. (Author abstract) 8 refs.

**096984 HALL COEFFICIENT FOR ELECTRONS IN A NEARLY FULL IMPURITY BAND.** At 3 K a change of sign of the Hall coefficient  $R_H$  of a 35% compensated n-InP crystal is observed where the variable-range hopping regime dominates the conductivity. This effect is not observed for a more compensated sample and is consistent with hopping conduction by holes in a nearly full band of localized donor impurity states. (Author abstract) 13 refs.

**096985 IMPURITY CONDUCTION IN SEMICONDUCTORS.** The role of the electron-electron interaction in impurity conduction which is crucial in determining the density of states for most compensations is considered. These new developments are discussed somewhat sketchily. We focus mainly on what is currently understood best: the physics of impurity conduction in lightly doped Ge and Si at small compensations. Discussions are also presented of a few other semiconductors where impurity conduction was reported (InSb, GaAs, and InP) and of other systems, such as semiconductors with magnetic ions and two dimensional systems with localized states. These offer new opportunities to study impurity conduction phenomena. 222 refs.

**096988 ELECTRONIC STATES AND STRUCTURAL PROPERTIES OF DEEP CENTERS IN SEMICONDUCTORS.** We present some general aspects and list some open problems in the field of pointlike deep centers in semiconductors that require an accurate knowledge of the short-range part of the impurity or defect potential, i.e., the details of its behavior in real space within the first few shells of nearest neighbors. We sometimes need a realistic theoretical description of the local electronic structure of a deep center even to get just a qualitative understanding of its experimental behavior. This review is focused on theoretical methods designed to study these challenging cases. A few simple qualitative ideas and general physical arguments, which provide a useful conceptual reference frame are reviewed. 189 refs.

**096990 BASIC PROGRAM ESTIMATING REDISTRIBUTED IMPURITY DISTRIBUTION ON HIGH TEMPERATURE SEMICONDUCTOR PROCESSES.** It is difficult to obtain the impurity distribution from an analytic solution, but the redistribution can be evaluated by a personal computer. This paper describes a fabrication method of a BASIC program for the impurity redistribution. The prepared program sets an assumed symmetrical impurity distribution for an initial condition, and obtains a numerical solution from a difference equation, which is made from the diffusion equation with the Crank-Nicolson's method, by the Gauss-Seidel's repetition method. An estimation for a transistor-base-impurity redistribution affected by an oxidation and emitter-diffusion-processes is illustrated. (Edited author abstract) 9 refs. In Japanese.

**096991 IMPURITY-BOUND ELECTRON IN QUANTUM WELL-HETEROSTRUCTURE-TYPE SYSTEMS.** The ground-state binding energy of a hydrogenic impurity is retrieved as a function of the effective dimensionality in a quantum well confinement. The geometry the authors use is a rectangular box, the dimensions of which can be tuned so as to yield a unified description interpolating between the bulk, the quasi-two- and one-dimensional limits as well as the quantum well box case. An interesting feature concerning the variation of the binding energy with the change in the geometry of the system is that  $E_B$  does not always increase monotonically as the dimensionality is reduced. For instance, when

either a or b is held fixed at a value comparable with  $\alpha^*$  and the remaining parameter is varied the authors observe that  $E_B$  goes through a minimum. (Edited author abstract). 7 Refs.

**096992 EFFICIENT SIMULATION OF COUPLED POINT DEFECT AND IMPURITY DIFFUSION.** A program has been developed which efficiently solves the coupled diffusion of interstitials, vacancies, and multiple impurity species in two dimensions. Due to the vast differences in diffusivities of the point defects and impurities, two separate spatial grids are used. A coarse grid is sufficient to represent the rapidly diffusing point defects, whereas a much finer grid is necessary to resolve the details of the impurity profile. Independent time steps are automatically selected for each species, permitting this extremely stiff system of diffusion equations to be solved in acceptable CPU time on a minicomputer. The simulation results are used to study the coupled diffusion of point defects and impurities under local oxidation conditions. Comparison with lap and stain measurements on structures with various widths of oxidizing and nitride-masked regions allows accurate values for numerous point defect diffusion parameters to be extracted. 42 refs.

**096995 SHALLOW IMPURITY INTERACTIONS AND THE METAL-INSULATOR TRANSITION.** A review is given of our current understanding of the interactions between shallow impurities in semiconductors at intermediate concentrations, particularly as seen through optical (far-infrared), dielectric and magnetic properties. Interpreted in terms of models appropriate for the non-metallic phase, these results point out the importance of randomness in the dopant distribution. Connection with the recent scaling approach to the metal-insulator transition, based on perturbative expansions about the high density metallic (weak-coupling) limit, is discussed.

**096996 LATTICE RELAXATIONS AT SUBSTITUTIONAL IMPURITIES IN SEMICONDUCTORS.** The positions of the crystal nuclei in the surrounding of substitutional impurities in Si and GaAs have been calculated using density-functional theory together with the local-density approximation for exchange and correlation and the total-energy gradient approach. These investigations give a qualitative explanation of the mechanism which drives the impurity-induced lattice relaxations as well as quantitative predictions of relaxation amplitudes up to far away from the defect. Both, the electronic screening charge at the impurity, and the long-range distortion pattern of the nuclei are found to be highly anisotropic, propagating mostly along the zigzag bonding chains of the (110) planes. Comparisons of the calculated distortions for Si:As<sup>+</sup> and GaAs:S<sup>+</sup> with two recent EXAFS analyses and for Si:S<sup>+</sup> with an EPR analysis show good agreement. (Author abstract) 57 refs.

**096998 ION IMPLANTATION AND LOW TEMPERATURE PROPERTIES OF METAL-SEMICONDUCTOR ALLOYS.** We review the experimental work on ion implantation with respect to superconductivity and electrical resistivity of metal-semiconductor alloys carried out at the Institute of Physics of Academia Sinica. Samples studied included liquid-quenched Al-Si-Ge ribbons and Al thin films. The liquid-quenched ribbons with a superconducting transition temperature  $T_c$  of 3.2 K were implanted with H or H<sub>2</sub> ions at room temperature and a decrease of  $T_c$  was observed. The ribbons were also implanted with Si ions at liquid nitrogen temperature, resulting in a higher onset of transition at about 4 K. We also implanted Si ions into Al thin films at room temperature up to 5 at.% Si. The  $T_c$  of the films increased from 1.5 to 1.9 K and the temperature-dependence of resistivity was changed from  $T^5$  to a  $T^3$ -dependence within 30-50 K. The superconductivity of Al-semiconductor alloys was proved to be strongly influenced by the disorder, which depends crucially on the implantation temperature. (Author abstract) 12 refs.

**097000 OBSERVATION OF STACKING-FAULT TETRAHEDRA IN III-V COMPOUNDS.** The first observations of stacking-fault tetrahedra in ion-implanted III-V compounds are reported. The structure and orientation of the stacking-fault tetrahedra are briefly described. The tetrahedra are present in the near-surface region that recrystallized during the annealing. High-resolution images suggest that the stacking-fault tetrahedra are of the vacancy type. (Author abstract) 16 refs.

**097001 MOLECULAR-ORBITAL METHOD FOR EVALUATING COMPOUND SEMICONDUCTOR RANGE PARAMETERS.** Using a molecular-orbital method, the range parameters of compound semiconductors are treated. The calculated results indicate that all III-V compounds and II-VI compounds deviate positively and negatively, respectively from Bragg's rule, and that the deviation coefficient does not depend on the implant energy but depends on the chemical bonding of the compounds. In addition, the calculated electronic stopping power of range parameters in negatively deviating systems ( $\text{He}^+ \rightarrow \text{CdS}$  and  $\text{CdTe}$ , and  $\text{B}^+ \rightarrow \text{HgCdTe}$ ) and positively deviating systems ( $\text{Li}^+ \rightarrow \text{Al}_2\text{O}_3$ ,  $\text{Si}^+ \rightarrow \text{GaAs}$ ,  $\text{Be}^+ \rightarrow \text{InP}$  and  $\text{N}^+ \rightarrow \text{GaP}$ ) are in good agreement with experimental results. The theoretical model and the method used for calculating are discussed. (Author abstract) 22 refs.

Wang, Dening (Acad Sinica, Shanghai, China); Wang, Weiyan. *Nucl Instrum Methods Phys Res Sect B* v B28 n 4 Nov 1 1987 p 488-492.

**097002 RESONANT NUCLEAR REACTIONS IN ANALYZING ION-IMPLANTED LAYERS.** Ion implantation is widely used to dope semiconductors, to modify solid surfaces, for gettering, to synthesize compounds, and for various purposes in radiation materials science. The bombardment itself and the subsequent operations distort the theoretical implanted-atom distributions. Nondestructive concentration profile monitoring is sometimes required in developing techniques. Resonant nuclear reaction methods are most suitable for light ions, which can be implemented with low-energy electrostatic accelerators ESA operating up to 2 Mv. Here the authors consider a universal method of determining concentration profiles without the resonance width constraint, which can be realized by means of standard ESA and a gamma spectrometer based on the Vektor system. 10 refs.

**097003 CHEMICAL TRENDS IN LATTICE LOCATION OF IMPLANTED IMPURITIES IN A<sup>III</sup>B<sup>V</sup> COMPOUNDS.** The lattice location and the electronic configuration of various groups of nontransition elements of the Periodic Table implanted in A<sup>III</sup>B<sup>V</sup> semiconductor compounds are discussed on the assumption that the local chemical bond plays the dominant role. Using this

scheme, a simple explanation is proposed for the discrepancy in the electrical activity of high-dose n- and p-type implants in GaAs. (Author abstract) 35 refs.

Antonicik, E. (Univ of Aarhus, Aarhus, Den). *Nucl Instrum Methods Phys Res Sect B* v B29 n 3 Dec 1987 p 490-499.

**097004 DOSE EFFECTS IN ION IMPLANTED COMPOUND SEMICONDUCTORS.** In this work a Monte-Carlo method of dynamical type is used to simulate the alteration of compound semiconductor targets of the III-V group, that is GaAs in InP, bombarded with Bi<sup>+</sup> and Si<sup>+</sup>. In the model account is taken of the presence of strains in the lattice and the results describe their effects on the behavior of the ions and on the formation of point defects and of concentration imbalances. (Author abstract) 22 refs.

Mazzone, A.M. (CNR, Bologna, Italy). *Appl Phys A* v A45 n 2 Feb 1988 p 113-118.

**097005 ION IMPLANTERS: CHEMICAL AND RADIATION SAFETY.** Recommendations to reduce chemical and radiation hazards for ion implanters are described along with pertinent regulations. Data are presented on production and maintenance operations. Routine chemical and radiation exposures during production operations are at least an order of magnitude below allowable limits. Airborne exposures during maintenance operations can be easily controlled by local exhaust ventilation and by keeping residues wet during cleaning operations. Without these controls, excessive exposure to airborne arsenic can occur, particularly when personnel clean source housing chambers of solid source arsenic implanters. (Author abstract) 27 refs.

**097006 STUDIES OF DEPTH PROFILES OF FLUORINE IN <sup>19</sup>F<sup>+</sup> ION IMPLANTED Pb<sub>1-x</sub>Sn<sub>x</sub>Te, CdTe AND Si.** The <sup>19</sup>F(P,  $\alpha$ )<sup>16</sup>O resonance nuclear reaction at E<sub>R</sub> = 872.1 keV, with width  $\Gamma$  = 4.2 keV, is used to measure the fluorine depth profiles in <sup>19</sup>F<sup>+</sup> ion implanted Pb<sub>1-x</sub>Sn<sub>x</sub>Te, CdTe and Si samples. Deconvoluting the experimental excitation curves by use of a reference function and parameter optimization procedure, the fluorine depth profiles are obtained, while the projected range distribution parameters, R<sub>p</sub>,  $\Delta R_p$  and SK for <sup>19</sup>F<sup>+</sup> ion implantation in Pb<sub>1-x</sub>Sn<sub>x</sub>Te, CdTe and Si are determined. These range distribution parameters are also calculated theoretically. The comparison between the experimental and theoretical results shows that the experimental R<sub>p</sub> and  $\Delta R_p$  agree well with the theoretical values. The possibility of studying the stopping powers of heavy ions at low velocities in solids by using resonance nuclear reaction technique is discussed. (Author abstract) 17 refs. In Chinese.

**097007 COMPUTER SIMULATION ANALYSIS OF THE PLANAR CHANNELING EFFECT IN PRACTICAL ION IMPLANTATION.** The planar channeling effect in ion implantation was studied using computer simulation. The simulation code was a modified MARLOWE code which enabled dynamic processes of amorphization due to high-dose ion implantation to be simulated. The authors simulated the practical ion implantation of 100 keV Si<sup>+</sup> ions in a 3 inch wafer of GaAs. Since an ion beam scans over a wide area, the angle of incidence of the ion beam changes from point to point on the wafer and results in considerable deterioration of uniformity in the ion-implanted depth, even though the angle of incidence was chosen so as to prevent the channeling condition from occurring during ion implantation. The result clearly indicates that a marked inhomogeneity in ion implantation takes place in the practical manufacturing processes. (Author abstract) 7 refs.

**097009 ION IMPLANTATION AND ANNEALING.** Ion implanters and ion sources are considered, along with Current Measurement. Range distribution and penetration anomalies are discussed. Furnace annealing, rapid thermal annealing and laser annealing are compared. Ion damage is dealt with. 47 refs.

Rimini, E. (Univ di Catania, Catania, Italy). *Cryst Semicond Mater and Devices, Trieste, Italy, 1984* Publ by Plenum Press, New York, NY, USA, 1988 p 591-622.

**097010 IMPROVED MODEL AND NUMERICAL SIMULATION FOR TWO DIMENSIONAL ION IMPLANTATION.** A new two-dimensional ion implantation model is presented. The two-dimensional distribution of the implanted impurity near an arbitrary shaped mask edge is described by a two half-Gaussian profile or a modified Pearson-IV distribution in the vertical direction and by a complementary error function in the lateral direction. The different stopping powers of the various mask materials for multi-layer mask have been considered. Using this model, an implantation process simulator has been developed which can continuously calculate the impurity profile for several times with different energy, dose and impurity. The effects of the various mask edges have been taken into account. (Edited author abstract) In Chinese. 8 refs.

**097014 NONDESTRUCTIVE ION-IMPLANT MONITORING USING LASER RAMAN SPECTROSCOPY.** A new Raman technique for monitoring low-dose ion implants is described. The capability for detection of implants of 20-50 keV B<sup>+</sup> (or equivalent BF<sub>2</sub><sup>+</sup> energies) at doses as low as approximately  $10^{10} \text{ cm}^{-2}$  is of particular interest. The feasibility of using the technique for monitoring V<sub>i</sub>-adjust implants is demonstrated. Low-energy B<sup>+</sup> and BF<sub>2</sub><sup>+</sup> ion implants in silicon were studied to determine the detection limits of the technique. Samples were analyzed immediately after implantation, without annealing. Implant doses in the range from  $3 \times 10^{16} \text{ cm}^{-2}$  to the detection limit of  $3 \times 10^{10} \text{ cm}^{-2}$  were characterized in this way. The technique is intended for application to in situ process monitoring for VLSI technology. 22 refs.

## Ionization

**097016 EFFECT OF PRIMARY IONIZATION IN AMORPHOUS SILICON DETECTORS.** The characteristics of the signal produced in amorphous silicon detectors have been studied with alphas and protons of energy in the range 400 keV to 5.8 MeV. The detectors are p-i-n structures fabricated by plasma decomposition of silane. They are operated under inverse polarization from 0 to 100 V. The collected charge is studied as a function of the energy deposited in the detectors. The mechanisms involved in the charge collection are analyzed and the consequences over future detector development are discussed. (Author abstract). 21 Refs.

**097020 BREAKDOWN OF CYCLOTRON RESONANCE IN SEMICONDUCTOR SUPERLATTICES.** The authors observed breakdown of cyclotron resonance in large magnetic fields oriented perpendicular to the growth direction in semiconductor superlattices. At small magnetic fields conventional cyclotron resonance is observed with the mass related to the miniband mass. At large magnetic fields, when the cyclotron diameter approaches the superlattices period, the resonance frequency appears to saturate and is determined by orbits impaled on the barrier. A model calculation gives good account of the magnetic field dependence of the resonance position and line width. (Author abstract) 10 refs.

**097021 INFLUENCE OF QUANTIZING MAGNETIC FIELD ON PARAMETERS OF ELECTRONS IN  $\text{Bi}_{1-x}\text{Sb}_x$  ALLOYS.** Pronounced influence of quantizing magnetic field  $H$  in ultraquantum limit on spin splitting factor  $\gamma = \Delta_{\text{spin}}/\Delta_{\text{orb}}$  and cyclotron mass  $m_c$  of electrons at  $L$  in n-type semiconductor  $\text{Bi}_{0.91}\text{Sb}_{0.09}$  alloy is observed. The decrease of cyclotron mass  $m_c$  and tending of  $\gamma$  to 1 with increasing  $H$  is explained by the decrease of the Fermi energy in ultra-quantum limit. Experimental results are in qualitative and quantitative agreement with the McClure and Choi theory. (Author abstract) 4 refs. In Russian.

**097022 ON ELECTRON STATES OF QUANTUM WELLS IN ULTRATHIN FILMS OF WIDE-GAP SEMICONDUCTORS IN AN ORIENTED MAGNETIC FIELD.** An attempt is made to investigate the effects of a tilted magnetic field on the size-quantized levels of quantum wells in ultrathin films of wide-gap semiconductors, taking n-GaAs as an example. It is found that the energy eigenvalue of the lowest Landau level

corresponding to a given electric subband increases with increasing magnetic field, and reaches a maximum corresponding to a given orientation of the field, the dependence being increasingly prominent with increasing size quantum numbers. Besides, the eigenvalue corresponding to the lowest electric subband decreases with increasing film thickness, the rate of decrease being significantly dependent on the magnetic field and its orientation. (Author abstract) 13 refs.

**097025 CRYSTALLOGRAPHIC AND MAGNETIC PROPERTIES OF THE SYSTEM  $(\text{AgInCd})_2(\text{CuIn})_2\text{Mn}_4\text{Te}_4(x+y+z=1)$  WITH  $x=3y$ .** Samples of the alloy system  $(\text{AgInCd})_2(\text{CuIn})_2\text{Mn}_4\text{Te}_4$  ( $x+y+z=1$ ) with  $x=3y$  were prepared by a melt and anneal technique. Lattice parameter values are measured and the limit of single phase behavior determined. Magnetic susceptibility measurements are made in the temperature range between 80 and 300 K. Values of the Curie-Weiss temperature and Curie constant are obtained from the susceptibility results. (Author abstract) 12 refs.

Quintero, M. (Univ de Los Andes, Merida, Venez); Sagredo, V.; Tovar, R.; Grima, P.; Perez, G.S. *Solid State Commun* v 64 n 4 Oct 1987 p 407-410.

**097026 ON THE INDUCED COBALT MOMENT IN  $\text{RCO}_4\text{B}$ -TYPE COMPOUNDS.** The results of magnetic measurements performed on  $(\text{Gd}_x\text{Y}_{1-x})\text{Co}_4\text{B}$  compounds in the temperature range 4.2-900 K are reported. The compounds with  $x \geq 0.2$  are ferrimagnetically ordered. The mean cobalt moment is dependent on composition. Above the Curie temperatures, the reciprocal susceptibilities obey a nonlinear dependence as function of temperature. By using a two sublattice model, the mean values of the molecular field coefficients characterizing the magnetic interactions inside and between sublattices are determined. The mean cobalt moments are linearly dependent on the exchange fields acting on these atoms. (Author abstract) 12 refs.

Burzo, E. (Central Inst of Physics, Bucharest, Rom); Creanga, I.; Ursu, M. *Solid State Commun* v 64 n 4 Oct 1987 p 585-587.

**097027 MAGNETIZATION AND SUSCEPTIBILITY OF  $\text{Pb}_{1-x}\text{Mn}_x\text{Se}$ .** Susceptibility and magnetization have been measured in samples of  $\text{Pb}_{1-x}\text{Mn}_x\text{Se}$  with small values of  $x$  over a temperature range from 2 to 300 K. The high temperature susceptibility followed the Curie-Weiss relation with a small paramagnetic Curie temperature that indicated a weak antiferromagnetic coupling among Mn ions. The high field magnetization could be fitted to a modified Brillouin function. (Author abstract) 6 refs.

Gorska, M. (Univ of Maryland, College Park, MD, USA); Anderson, J.R. *Solid State Commun* v 63 n 11 Sep 1987 p 1055-1058.

**097028 STUDY OF THE NATURE AND PROPERTIES OF  $\text{V}_{1-x}\text{Cu}_x\text{O}_2$  SOLID SOLUTIONS ( $0 \leq x \leq 0.04$ ).** It is shown that for  $x \leq 0.02$   $\text{V}_{1-x}\text{Cu}_x\text{O}_2$  solid solutions ( $0 \leq x \leq 0.04$ ) are isostructural with pure vanadium dioxide. In the investigated samples a semiconductor-metal phase transition is observed. For  $x > 0.02$  a redistribution of the copper ions occurs. Copper additives lower the semiconductor-metal phase transition temperature and stabilize the intermediate insulating phase. The temperature dependence of the magnetic susceptibility of the semiconducting phase of  $\text{V}_{1-x}\text{Cu}_x\text{O}_2$  attests to the formation of paramagnetic centers as a result of breakage of  $\text{V}^{4+}-\text{V}^{4+}$  bonds due to charge compensation. The number of paramagnetic centers is proportional to the copper concentration in the solid solution for  $x \leq 0.02$ . In Russian. 12 refs.

Kellerman, D.G.; Gorshkov, V.S.; Belysheva, G.M.; Khodos, M.Ya.; Perelyaev, V.A. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 10 Oct 1987 p 1678-1682.

**097029 MAGNETIC EFFECTS IN NONCRYSTALLINE SEMICONDUCTORS.** The normal diamagnetic behavior of amorphous semiconductors is discussed along with paramagnetic effects such as those due to native defects or impurities or to optically induced changes in the material. Relaxation mechanisms for electronic spins via the atoms in the lattice (spin-lattice relaxation) are summarized. Results of NMR and NQR measurements in amorphous semiconductors are discussed. These results include the use of NMR and NQR as probes of local bonding arrangements and the use of nuclear spin-lattice relaxation to probe low energy vibrational excitations or impurity species in amorphous semiconductors. Applications of Mossbauer and ODMR spectroscopy to amorphous semiconductors are summarized. 159 refs.

Taylor, P. Craig. *Noncryst Semicond* Publ by CRC Press Inc, Boca Raton, FL, USA, 1987 p 69-110.

**097030 MAGNETORESISTANCE OF LOW STAGE GRAPHITE ACCEPTOR COMPOUNDS.** The angular dependences of magnetoresistance (ADM)  $\Delta\rho/\rho_0$  versus the angle  $\Theta$  between the magnetic field direction and the sample c-axis of the graphite intercalation compound (GIC) are calculated. Comparison of the obtained theoretical dependences with the experimental data is carried out for the stage-2  $\text{C}_{10}\text{CuCl}_2$  and  $\text{C}_{10}\text{ICl}$  compounds, and also for the stage-1 heterointercalated compound  $\text{C}_{10}\text{CuCl}_2 \cdot 0.6 \text{ ICl}$ . It is shown that three dimensional model with the c-axis dispersion of the current carriers is in much better correspondence with the experimental data than two dimensional one. (Author abstract) 12 refs.

## Manufacture

**097031 NEW WAY TO MAKE CRYSTALS FOR SEMICONDUCTOR USES.** In the competitive world of substrate manufacturing, some firms are trying less-costly and more-manageable changes in methods to obtain silicon and gallium arsenide crystals. Some of the topics discussed are crystal growing, doping; Czochralski growth; pressure factor; and semiconductor material economics.

Parkinson, Gerald (Chemical Engineering, New York,

NY, USA); Ushio, Shota; Lewald, Roon; Hunter, David. *Chem Eng (New York)* v 94 n 8 May 25 1987 p 14-15, 17.

**097032 IMPULSIVE THERMOPROCESSING OF SEMICONDUCTOR PLATES.** Impulsive thermoprocessing of materials has played an ever-increasing role in the technology of semiconductor production in recent years. Use of impulsive heating methods permits reduction to a minimum of negative affects associated with long-term high-temperature processing, as well as a reduction in the amount of time required for various technological operations. Thermal processing of semiconductors by short pulses producing the adiabatic regime, for example, when laser radiation is used, has a number of serious drawback. Among these are significant mechanical stresses produced upon local heating of the crystal, as well as high temperature gradients and cooling rates, which produce inadmissible concentrations of point defects which require subsequent low temperature annealing in the furnace. Therefore the adiabatic regime will not be considered in the present study. This paper discusses the processes occurring within the plate in the thermal balance regime. 14 refs.

## Marketing

**097033 PROCEEDINGS OF THE TWELFTH ANNUAL COMMODITY MEETING OF THE INSTITUTION OF MINING AND METALLURGY.** This issue of the journal contains five papers presented at a meeting. The subjects covered include metals in electronics, geological occurrence of these elements, factors affecting availability, features of germanium and gallium supply and demand, and gallium arsenide from mine to microcircuit. All papers are abstracted separately. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11652 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

Anon (Inst of Mining & Metallurgy, London, Engl). *Trans Inst Min Metall Sect C* v 97 Mar 1988, Proc of the Twelfth Annu Commodity Meet of the Inst of Min and Metall, London, Engl, Dec 3 1987 p C31-C52.

**097034 FACTORS AFFECTING AVAILABILITY OF ELECTRONIC METALS.** It is the author's contention that the development of markets for electronic metals is hampered by uncertainties about their availability and price. The biggest single problem facing the potential new user is the lack of definitive information on production, consumption and stocks. The paper covers sources, trade policy, stockpiles and pricing. Comments are addressed to the case of gallium arsenide.

**Mathematical Models** See Also DIELECTRIC MATERIALS—Electromagnetic Field Effects; ELECTRIC CONDUCTIVITY—Mathematical Models; ELECTRONS—Tunneling; FERROMAGNETIC METALS—Magnetic Field Effects.

**097035 DEFORMABLE SEMICONDUCTORS WITH INTERFACES: BASIC CONTINUUM EQUATIONS.** A conceptually simple, but nonetheless nonlinear, rotationally invariant and thermodynamically admissible, continuum theory of deformable semiconductors is presented on the basis of (1) general principles of continuum physics including the effects of singular surfaces and energy-carrying interfaces and (2) a systematic use of the principle of virtual power for finite velocity fields. The presence of a singular 'thermodynamic' surface provides proper boundary conditions at the interface, so that no restrictions need to be made concerning the value of surface electric entities in problems dealing with surface-wave propagation. The primitive nonlinearity is essential in that it guarantees obtaining a consistent set of linearized equations about a state exhibiting bias fields.

**097039 SPACE-CHARGE-LIMITED CURRENTS IN MATERIALS WITH NONLINEAR VELOCITY-FIELD RELATIONSHIPS.** A general parametric form of the current-voltage characteristic of space-charge-limited currents (SCLC) is derived in the virtual cathode approximation. The result is used to obtain several exact solutions for the trap-free insulator that is characterized by a nonlinear velocity-field (v-F) relationship. The solutions describe the gradual transition from the regime of constant mobility to that of the field-independent drift velocity. The first-order and second-order corrections to the Mott-Gurney law are then obtained in a closed form for an important class of velocity-field relationships. Exact solutions are also obtained for v-F models that exhibit negative differential mobility behavior. The theory is in good agreement with existing experimental data. The general result is used to specify the condition that allows the anode field as well as the v-F dependence to be extracted from experimental current-voltage characteristics without assuming any a priori v-F relation. 25 refs.

**097041 DEPENDENCE OF LIFETIME ON DESIGN PARAMETERS OF AN nipi DOPING SUPERLATTICE: RESULTS OF SELF-CONSISTENT CALCULATIONS.** This paper presents a scheme for calculating recombination lifetimes in a doping superlattice at arbitrary temperatures and forward biases. The scheme involves the self-consistent calculation of sub-band energies, populations and envelope functions, followed by the calculation of lifetime using overlap integrals. Results of these calculations are then presented for a variety of combinations of layer thicknesses and dopings, all at a temperature of 300 K and a forward bias of 1 V. Our results give room temperature lifetimes as high as approximately 30 ms for n and p layer thicknesses of 750 Angstrom each, i-layer thickness of 50 Angstrom, and dopings in the n and p layers of  $2 \times 10^{18} \text{ cm}^{-3}$ . ## Mechanical Properties

**097045 PREPARATION AND MICRO-HARDNESS STUDIES ON SOME V-VI-VII GLASSY COMPOUNDS.** V-VI-VII group compounds are semiconductors and some of them show ferroelectric, photoelectric, piezoelectric properties. Glassy materials of these group compounds show interesting optical and magnetic optical

properties. The glasses of these materials are used as IR detectors and also as memory storage devices. The initial compounds SbSi, BiSeI and AsSeBr were prepared from elements of Antimony (99.999%), Bismuth (99.999%), Arsenic (99.999%), Sulphur (99.999%), Selenium (99.999%) and resublimed analar grade (99.9%) iodine, taken stoichiometrically by vacuum fusion. Micro hardness studies were done using Leitz pyramidal indenter. The loads were varied from 2 to 100 gms. The effect of varying indentation time for different loads and effect of annealing time with hardness will be discussed. (Edited author abstract)

**097048 IN SITU HIGH-RESOLUTION ELECTRON MICROSCOPY REACTIONS IN SEMICONDUCTORS.** An assessment has been made of the feasibility of performing in situ electron microscopy experiments, under high-resolution imaging conditions at high temperature. The particular field of interest is that of interface reactions in semiconductor systems. It is found that the image quality is sufficiently good, especially with new medium-voltage instruments, that changes in the specimens can be followed by extensive periods of time. Results on the solid phase epitaxial regrowth of silicon compare well with those obtained from high-voltage electron microscopy and Rutherford backscattering spectroscopy studies on the same materials. The behavior of some metal-gallium arsenide reactions (specifically Ti-GaAs and Ni-GaAs) has also been investigated. The influence of extremely thin foils is unpredictable at present. (Author abstract) 32 refs.

**Microstructure** See Also SEMICONDUCTING SILICON—Etching.

**097051 BOND LENGTHS IN III-V TERNARY ALLOY SEMICONDUCTORS.** An analysis was applied to 18 different III-V ternary alloy semiconductors. A thermodynamical approach was taken in order to derive relative numbers or statistics of tetrahedron cells, and then the average bond lengths were theoretically calculated. To this extent, they would give us a basic idea of the microstructure of alloy semiconductors. The theoretical results of  $In_{1-x}Ga_xAs$  and  $GaAs_{1-x}P_x$  agree fairly well with experimental data from extended X-ray absorption fine structures. (Author abstract) 17 refs.

Sasaki, Akio (Kyoto Univ, Kyoto, Jpn); Ichimura, Masaya. *Jpn J Appl Phys Part 1* v 26 n 12 Dec 1987 p 2061-2066.

**097052 HIGH-TEMPERATURE LATTICE THERMAL EXPANSION OF SOME MIXED CRYSTALS OF THE  $CuGe_2P_3$ - $Cu_2GeS_3$  SYSTEM.** In the compounds  $CuGe_2P_3$  and  $Cu_2GeS_3$  the anion sites are occupied by phosphorus and sulphur respectively, and the cation sites are shared by copper and germanium in both the compounds. Therefore, when  $Cu_2GeS_3$  is added to the  $CuGe_2P_3$ , the phosphorus atoms would be replaced by sulphur atoms at the anion sites and germanium by copper at the cation sites. Thus  $Cu_2GeS_3$  forms a continuous series of solid solution with  $CuGe_2P_3$  especially when the former is in the cubic form. As a part of a general programme of X-ray diffraction studies on zinc-blende type semiconductors, the authors have reported data on lattice parameters and thermal expansion of  $CuGe_2P_3 + 0.5 Cu_2GeS_3$  and  $CuGe_2P_3 + 0.8 Cu_2GeS_3$ . This letter reports similar work on  $CuGe_2P_3 + 0.2 Cu_2GeS_3$  and a comparison of the data on thermal expansion of all the compounds. 15 refs.

**097055 SCATTERING THEORY FOR QUASI-ONE-DIMENSIONAL TUNNELING STRUCTURES.** Quantum theoretical studies of semiconductor microstructures are most naturally done in terms of one-dimensional scattering states, which are characterized far from a structure by k-dependent reflection and transmission amplitudes. We have investigated these states using integral forms such as the Lippmann-Schwinger equation. These allow us to obtain global properties of the states and provide the basis for a formal scattering theory of the kind that has been developed for the conventional problem of three-dimensional potential scattering. We find orthonormality relations for the scattering states, the one-dimensional analogues of Wigner's inequality and Levinson's theorem, and associated properties of the complex-momentum transmission amplitude. **097071 TIME-DEPENDENT INFORMATION DEPTH IN OPTICAL PROBING OF SEMICONDUCTOR MATERIALS AND DEVICES.** The authors consider the interaction of a time varying focused light beam with a semi-infinite semiconductor. The volume which the photogenerated carriers probe as a function of time after the light beam is switched on is considered by

introducing an information depth within which the majority of the carriers are generated. The effects of surface recombination velocity and absorption on the information depth are discussed. (Edited author abstract). 20 Refs.

**097072 OPTICAL STUDY OF  $Hg_{1-x}Cd_xTe$  GRADED GAP MATERIAL.** Layers of the ternary compound  $Hg_{1-x}Cd_xTe$  are often graded band gap II-VI semiconducting systems. Epitaxial layers of this compound are obtained by depositing  $HgTe$  from the gaseous phase on  $CdTe$  single crystals under controlled  $Hg$  pressure. The energy gap of this compound changes as a function of layer thickness and thus composition. The molar composition  $x = 0.2$  is required for devices working in the infrared region. The collection efficiency is high enough for photovoltaic application. Optical measurements for selected layers have been performed to get information about the composition and energy gap gradient with layer thickness. 6 Refs.

**097073 ON THE BAND GAP DEPENDENCE OF REFRACTIVE INDICES OF SOME QUATERNARY III-V AND II-VI COMPOUNDS OF DEVICE INTEREST.** With increasing applications of ternary and quaternary alloys of III-V and II-VI compounds in optoelectronic devices like emitters, detectors, modulators and mixers, the materials given are promising candidates. Of the attempts to predict the refractive indices of mixed semiconductor crystals, the model proposed by D.K. Ghosh et al. has been found to be fairly successful. This note demonstrates the credibility of the model in predicting the refractive indices of those crystalline alloys within their miscibility range and compares them with experimental values. 13 Refs.

**097074 ON THE OPTICAL STARK EFFECT OF EXCITONS IN SEMICONDUCTORS.** The so-called optical or dynamical Stark effect of excitons in semiconductors is studied by applying a two-band density matrix approach. It is found that the effect of a Stark-like field induced modification of the excitonic envelope function can be neglected. A pump pulse below the exciton resonance leads to a blue-shift and a bleaching. These two effects are linked in such a way that the shift can at most be of the order of the dephasing rate. The essential features of the effect are found to be present already in the two-level approximation where other resonances and the absorption continuum are neglected. (Author abstract). 10 Refs.

**097075 NONLINEAR REFRACTION AND INCREASING ABSORPTION IN  $HgCdTe$  OPTICAL BISTABILITY AT ROOM TEMPERATURE: AN EXPERIMENTAL STUDY.** The effects of nonlinear absorption in optical bistability as observed at room temperature in  $Hg_{0.815}Cd_{0.185}Te$  s investigated. As intensity is increased, a new feature for  $HgCdTe$  is observed, namely the transition in transmission from anticlockwise hysteresis loops. This transition is not present in reflection. Our observations are consistent with the assumption of thermally induced changes in the nonlinear optical properties of the semiconductor. (Author abstract). 12 Refs.

Cecchi, S. (Istituto Nazionale di Ottica, Florence, Italy); Coppo, P.M.; Salieri, P.; Arecchi, F.T. *Opt Commun* v 67 n 4 Jul 1988 p 305-310.

**097076 LMTO CALCULATION OF THE OPTICAL-PHONON DEFORMATION POTENTIALS OF CUBIC SEMICONDUCTORS.** The optical-phonon deformation potentials of the cubic semiconductors GaP and GaAs have been investigated by LMTO-ASA approach

within the frozen-phonon approximation. Some of the different treatments in frame of the LMTO method are examined and compared with the nonlocal empirical pseudopotential method (NEPM). The investigation indicates that the results of the frozen-potential model, in which the displacement of empty spheres is synchronized with the vibration of atomic spheres, are closest to that of the NEPM in a variety of LMTO treatments. The agreement between this approach and experiment is not inferior to one of the NEPM, thus providing the optical deformation potentials of zinc-blende semiconductors with a feasible ab initio calculation. (Author abstract). 7 Refs. In Chinese.

**097077 DETERMINATION OF THE OPTICAL CONSTANTS  $n$ ,  $k$  OF  $Zn_3In_2S_6$  AND  $Zn_5In_2S_8$  FROM TRANSMISSION MEASUREMENTS.** Thin layers of  $Zn_3In_2S_6$  and  $Zn_5In_2S_8$  laminated compounds are used to obtain interference modulated transmission spectra at normal incidence with unpolarized light. An analysis based on the use of the extremes of the fringes in the transparent region is applied in order to determine the real and imaginary parts of the refractive index, as well as the thickness of the specimens. The equation  $2nd = m\lambda$ , helps to estimate  $n$  in the region of strong absorption so that the optical constants are finally determined in the spectral region 450 to 700 nm. Ellipsometric measurements are used to crosscheck the results at  $\lambda = 632.8$  nm. (Author abstract). 5 Refs.

Kalomiros, J.A. (Aristotle Univ of Thessaloniki, Thessaloniki, Greece); Spyridelis, J. *Phys Status Solidi A* v 107 n 2 Jun 1988 p 633-637.

**097078 OPTICAL PROPERTIES OF  $TiB_2$  MONOCRYSTALS.** Above some temperature, rhombohedral phases of  $TiB_2$  have a disordered cubic structure with respect to cations, that allows their treatment as  $Al^{IV}B^{VI}$  pseudocompounds ( $PbTe$ ,  $PbSe$ ,  $PbS$ ). The wide regions of solid solutions that form  $TiB_2$  with  $Al^{IV}B^{VI}$  compounds confirm the above statement. According to the theoretical investigations rhombohedral phases of  $TiB_2$  on the basis of antimony have an inverse spectrum, but the latter of those based on bismuth is normal. Owing to this there are systems among the solid solutions based on  $TiB_2$  and  $Al^{IV}B^{VI}$  compounds, in which a transition through the gapless state is realized. This stimulates interest in an experimental investigation of the optical properties of rhombohedral phases ( $D_{3d}$ ) of  $TiB_2$ -group semiconductors. In the present note the results of transmission and reflection measurements of n- $TiB_2$  are reported. 10 Refs.

**097079 RADIATIVE AND NON-RADIATIVE POLARITON STRUCTURE OF SUPERLATTICES.** Optical properties of multilayered materials are considered. We emphasize polaritons of semi-infinite superlattices, that is, superlattices which exhibit a free surface. In these thin-film structures, the accumulation of interfaces gives rise to peculiar electromagnetic eigenmodes, distributed as continuous frequency bands. The termination of the superlattice at the surface modifies the density of these modes. In particular, one notices the appearance of isolated branches analogous to surface polariton modes of semi-infinite homogeneous materials. We describe radiative and non-radiative modes, including finite life-time effects, from the point of view of scattering theory, using a Green's function technique. The local density of states of the polariton modes is calculated and provides a complete information on the allowed electromagnetic excitations, as a function of wavelength, at any depth in the superlattice. The results are used to discuss reflectance and attenuated total reflection experiments on superlattices. (Edited author abstract). 18 Refs.

**097080 ELECTROREFRACTION AND ELECTROABSORPTION IN  $InP$ ,  $GaAs$ ,  $GaSb$ ,  $InAs$ , AND  $InSb$ .** Effective-mass theory is used to calculate electric-field-induced changes in optical refraction and absorption (the Franz-Keldysh effect) in five direct-gap III-V semiconductors:  $InP$ ,  $GaAs$ ,  $GaSb$ ,  $InAs$ , and  $InSb$ , covering the 0.88-to-10- $\mu$ m wavelength range. The magnitude of the effect is determined by fitting experimental absorption data. Results are given for photon energies from the bandgap to 100 meV below the gap for applied electric fields from  $3 \times 10^3$  to  $3 \times 10^5$  V/cm. Values of  $\Delta n$  and  $\Delta k$  as large as  $10^{-3}$  to  $10^{-2}$  are found. The results are applicable to integrated-optic devices including switches and modulators. 39 Refs.

**097081 PAIRED TEMPERATURE SPECTROSCOPY (PATS) FOR GAP STATES IN ORDERED AND DISORDERED SEMICONDUCTORS - I. THEORETICAL ANALYSIS.** Paired temperature spectroscopy (PATS) is a recently proposed transient-capacitance-based technique to characterize trap parameters in semiconductors. One constructs a PATS signal by subtracting the capacitance transients at two distinct temperatures. The extrema of this signal contain the information of the trap parameters. We present a detailed theoretical analysis of PATS. The analysis includes studies of the sharpness of the PATS extrema, error estimation and the ability of PATS to resolve traps with proximal activation energies. The analysis is extended to disordered semiconductors where one has a distribution of activation energies. The suitability of PATS is established, particularly, for analyzing metastable defect centers. (Author abstract) 14 Refs.

**097082 THERMOELECTRIC EFFECTS IN THE QUANTUM HALL REGIME.** The transport properties of a disordered two-dimensional semiconductor system are investigated in the limit of high magnetic fields. The longitudinal thermopower as a function of the electron concentration is shown to vanish in the plateau regimes of the Hall conductivity - in agreement with experiments. Similar to the quantum Hall effect, this low temperature phenomenon is due to localization by a random potential. (Author abstract) 26 Refs.

Oscillations See Also SEMICONDUCTOR DIODES, PHOTODIODE—Oscillations.

**097083 RADIAL OSCILLATIONS OF AN ELASTIC SEMICONDUCTOR.** We consider the radial oscillations of a cylindrical tube, under an applied traction on its inner and outer surfaces which are carrying charges and are maintained at constant temperature, the relaxation times and coupling coefficients having been neglected. The material of the tube is taken to be a deformable, transversely isotropic, heat conducting and polarized semiconductor in the presence of an electric field. We look for the interaction of mechanical, thermal and electric fields in the tube. Stress distribution, the velocity and acceleration of the oscillation, temperature field, free electrons and hole charge distribution, the electric intensity distribution at any point inside the tube are determined. That one of the shear stresses, when compared with the purely elastic solutions, does no longer vanish is due to the interaction of the various fields. Oscillations are, on the whole, damped. (Edited author abstract) 3 Refs.

**097085 DEPENDENCE OF LAYER THICKNESS ON FINAL CELL VOLTAGE FOR ANODIC OXIDE FILMS GROWN GALVANOSTATICALLY ON  $Hg_{1-x}Cd_xTe$  ( $x=0.02, 0.16, 0.20, 0.22, 0.34, 1.00$ ).** Anodic oxidation is an established technology for manufacturing insulating layers on the alloy semiconductor  $Hg_{1-x}Cd_xTe$ . Because of the high relative dielectric constant of the anodic oxide, it can be successfully applied in MIS and MISFET devices where a high insulator capacitance for layers thick enough to diminish breakdown effects and technological failure is needed. In order to obtain an oxide layer with a desired thickness, the relation between thickness and process parameters must be known. It was the aim of the present note to investigate the dependence of the anodic oxide thickness on  $Hg_{1-x}Cd_xTe$  on the final cell voltage in the galvanostatic regime over a wide range of  $x$ . 7 refs.

**097086 OBSERVATION OF IN SITU AND EX SITU OXIDATION PROCESSES FOR ZnTe SURFACES BY HIGH-RESOLUTION ELECTRON MICROSCOPY.** The oxidation of ZnTe surfaces, both in situ and ex situ, is studied by high-resolution electron microscopy. For in situ oxidation, the oxidation sequence involved amorphization of the ZnTe crystal as Te is removed by a non-thermal electron stimulated process, with subsequent formation of hexagonal ZnO by oxygen diffusion into the sample. In ex situ oxidation, the main phases present are crystals of ZnO and Te metal, which usually give rise to layered surface regions, in the sequence ZnTe/Te/ZnO, with the large crystals (up to 100 nm) of Te in an epitaxial relationship with the bulk ZnTe and the small ZnO crystals (5 nm) in random orientations. This process involves the diffusion of Zn from the bulk ZnTe to the surface followed by reaction with oxygen in air to form ZnO. (Edited author abstract). 21 Refs.

## Phase Diagrams

**097088  $PbIn_2Se_4$ - $PbGa_2Se_4$  SECTION OF THE QUASI-TERNARY SYSTEM  $PbSe$ - $In_2Se_3$ - $Ga_2Se_3$ .** Using methods of physicochemical analysis, a study was

made of the interaction over the  $PbIn_2Se_4$ - $PbGa_2Se_4$  section of the  $PbSe$ - $In_2Se_3$ - $Ga_2Se_3$  system, and the phase diagram of this section was plotted. It was established that the range of  $PbIn_2Se_4$ -based solid solutions at 300 K amount to 2 mol.%  $PbGa_2Se_4$ . The electrophysical properties of the solid solutions were studied in a wide temperature range. Alloys of  $PbIn_2Se_4$ -based solid solutions are p-type semiconductors with an electric-conductivity activation energy of 1.22-1.00 eV. 3 refs. In Russian.

**097089 PHASE DIAGRAM OF  $CuAl_xIn_{1-x}S_2$  SOLID SOLUTIONS.** The  $CuInS_2$  and  $CuAlS_2$  semiconducting compounds are promising materials for fabricating solar cells.  $CuAlS_2$  a candidate for blue to ultraviolet light emitting diode applications. The aim of the note is to plot the phase diagram of system and to carry out a thermodynamic analysis of the phase equilibrium. The concentration dependences of the heats of mixture both in the solid and liquid phases are sign changing functions with a flex point which is indicative of the complex character of interatomic interactions. 7 refs.

Aksenov, I.A. (Acad of Sciences of the Byelorussian SSR, Minsk, USSR); Makovetskaya, L.A.; Popelnuyk, G.P.; Shilovich, I.P. *Phys Status Solidi A* v 105 n 2 Feb 1988 p K97-K102.

**097090 PHASE RELATIONS AND THE EFFECTS OF ORDERING IN  $(AgIn)_{1-x}Mn_{2x}Te_2$  AND  $CuIn_{1-x}Mn_{2x}Te_2$  ALLOYS.** Polycrystalline samples of the semimagnetic semiconductor alloys  $(AgIn)_{1-x}Mn_{2x}Te_2$  and  $(CuIn)_{1-x}Mn_{2x}Te_2$  were used in lattice parameter, optical energy gap  $E_0$ , and differential thermal analysis (DTA) measurements. The results indicate that in the zinc blende and chalcopyrite ranges of composition, ordering of the manganese can occur at lower temperatures, and a combination of the results is used to delineate the composition and temperature ranges in which disordered  $\alpha$  and ordered  $\alpha'$  chalcopyrite and disordered  $\beta$  and ordered  $\beta'$  zinc blende is the equilibrium structure. While the manganese ordering has little effect on the lattice parameter, it has an appreciable effect on the values of  $E_0$ . This is demonstrated by the different aiming points at  $z = 1.0$  for the  $E_0$  vs.  $z$  lines in the different fields, the values being 2.8 eV for  $\beta$ , 1.95 eV for  $\beta'$ , and 1.35 eV for  $\alpha'$ . (Author abstract). 17 Refs.

**097091 IONOGRAPHIC PATTERNS WITH AMORPHOUS/CRYSTALLINE CONTRAST.** Ion irradiation of thin layers of crystalline semiconductors induces a phase transition to the amorphous state. The concomitant optical contrast between unirradiated, crystalline, and irradiated, amorphous material may be used for pattern fabrication in the submicron range. This process is explained by the example of silicon single-crystal layers on sapphire. (Author abstract) 3 refs.

Kalbitzer, S. (Max-Planck-Inst fuer Kernphysik, Heidelberg, West Ger). *Appl Phys A* v A44 n 2 Oct 1987 p 153-155.

**097092 PRESSURE-INDUCED TRANSITIONS IN AMORPHOUS  $Tl_xSe_{100-x}$  ALLOYS.** The electrical resistivity of bulk semiconducting amorphous  $Tl_xSe_{100-x}$  alloys with  $0 \leq x \leq 25$  has been investigated up to a pressure of 14 GPa and down to liquid-nitrogen temperature by use of a Bridgman anvil device. All the glasses undergo a discontinuous pressure-induced semiconducting-to-metal transition. X-ray diffraction studies on the pressure-recovered samples show that the high-pressure

phase is the crystalline phase. The pressure-induced crystalline products are identified to be a mixture of Se having a hexagonal structure with  $a=4.37$  Angstrom and  $c=4.95$  Angstrom and TlSe having a tetragonal structure with  $a=8.0$  Angstrom and  $c=7.0$  Angstrom. (Author abstract) 15 refs.

**097093 DIELECTRIC ANOMALY AT THE METAL-INSULATOR TRANSITION AS SEEN BY ELECTRON SPIN RESONANCE. 1. ANALYSIS OF THE ESR LINE SHAPE FOR POOR CONDUCTORS.** The shape of the electron spin resonance (ESR) line for itinerant electrons is asymmetric. The asymmetry is due to a microwave phase shift inside the sample. A complete equation for the power absorbed in conducting media is derived in this paper; it includes spin diffusion, sample size and displacement-current effects. This new formalism is appropriate to study the ESR of heavily doped semiconductors. It is shown that ESR may be a powerful technique to measure the dielectric constant in these media. (Edited author abstract) 18 refs.

**097094 APPARATUS AND METHOD OF DETERMINING THE THERMAL EFFECTS OF PHASE TRANSFORMATIONS BY DIFFERENTIAL THERMAL ANALYSIS.** A variety of calorimeters with differing accuracies, complexities, ease of use, and expense are commonly used to determine thermal effects. In a number of cases an express determination of the phase transformation thermal effects, such as melting, is needed. There is practically no information about the thermal effects in complex semiconducting systems in the literature, and available data on the heat of fusion of semiconducting III-V compounds differ by 2-3 times. Consequently, an apparatus and a method for the express determination of thermal effects are proposed in this paper on the basis of a differential thermal analysis apparatus similar to those found in many research laboratories. 6 refs.
